The "Tikker."—Such an arrangement is shown diagrammatically in Fig. 97. In this figure T is a rapidly rotating cog-wheel against which a small metal tongue rests lightly. The use of such an interrupter is the invention of the Danish scientist Pedersen, who used it for reception of signals from the famous arc-transmitting system which bears Poulsen's name. Pedersen called the interrupter a "tikker," and this is the name by which the device is still known.

The cog-wheel T may conveniently be the fastest-moving wheel in the mechanism of a clock. It will be necessary to remove the escapement so that the wheels rotate freely. If the spring is now wound up and the mechanism allowed to run it will go at a tremendous speed and be run down in a few seconds; a governing device must, therefore, be added, and this can easily be done by soldering, or otherwise fixing, a small vane cut out of thin sheet brass to the most rapidly revolving spindle as shown in Fig. 98. Owing to the friction of the air with this vane the mechanism will not be able to "race," and will run nicely for a considerable time. The actual size of the vane for best working will depend on the nature of the clockwork and will have to be determined in individual cases by trial; the larger the vane the slower the mechanism will run. In the writer's own tikker the vane is only ¾ in. across and ¼ in. wide, but it is sufficient to ensure a steady run of about twenty minutes. The only other thing that remains to be done is to fix a light tongue which has to make contact with the cogs of the fastest wheel in the train.

The method of mounting is shown in Fig. 99. A is an ebonite strip, sufficiently thick to be rigid, through which a hole has been made at each end. By means of a bolt and fly-nut one end of the ebonite strip is fixed to a point C in the frame, and that at the other end will come near the wheel T, a hole being made at C to accommodate the bolt. The tongue B is cut to the shape shown in Fig. 100 out of springy sheet brass about the thickness of drawing-paper. An ordinary pair of scissors will cut the brass quite easily, and the

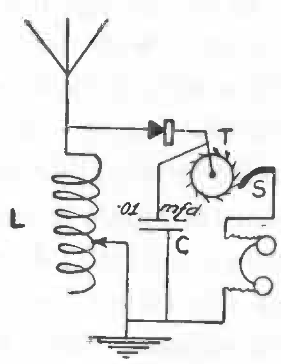

Fig. 97.—Circuit Diagram of Interrupter.

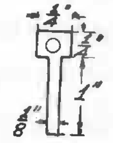

Fig. 100. —Metal Tongue.

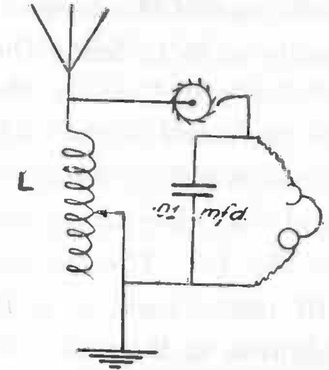

Fig. 101.—Pedersen System of C.W. Reception.

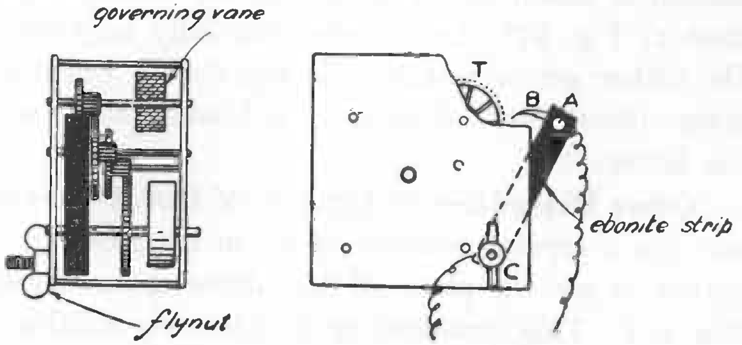

Fig. 98

Fig. 99

Figs. 98 and 99.—Front and Side Elevations of Interrupter.

hole shown in the wide end may be pushed through by any sharp tool. The tongue is fastened to the upper end of the ebonite strip A by means of a nut and bolt through the hole which has been made there, and the thin part of the tongue is given a twist through a right angle so as to bring the free end square with the teeth of the wheel T. A piece of flexible wire is connected to the clock-frame and another to the tongue ; one of these wires is connected to one of the phone leads and the other to one of the detector terminals as shown in Fig. 97. The condenser C, having a capacity of about .01 microfarad, is shunted across the tikker and telephones, as it greatly improves the signals. Some little adjustment of the speed of the tikker may be necessary before good results are obtained. When a C.W. station is tuned in (by means of the variable inductance L, Fig. 97), the detector carefully adjusted and the tikker set in motion, the signals are heard as an intermittent musical note or a hissing note, usually the latter.

Other Methods.—As a matter of fact, Pedersen did not use a crystal detector at all in his receiver. The tikker is put in place of the detector as shown in Fig. 101. This arrangement is extremely reliable, but, in the writer's experience, is not quite so sensitive as when a crystal detector is included. However, as crystal detectors are very liable to go out of adjustment the writer would recommend the method shown by Fig. 101.

Where a crystal detector is to be used, either a good piece of zincite touched by a sharp piece of

bornite or copper pyrites, or a piece of galena touched by a small spiral of 40-gauge copper wire, will be the most suitable. Crystals, like carborundum, which require a battery and potentiometer, cannot be used satisfactorily in conjunction with a tikker. Much depends on getting good specimens of crystal.

A gramophone can be used as a tikker by connecting one wire to the works and allowing the other to rub lightly against the edge of the revolving turntable

CHAPTER XIII

Making a Wavemeter from a Crystal Set

The components of a crystal set—or some of them—can be assembled to produce a wavemeter that gives approximately truthful results.

With a coil of known inductance, a variable condenser, crystal and phones, a useful wavemeter can be rigged up. The circuit is as shown in Fig. 102.

First calculate from the formula:

$$1{,}885 \sqrt{L \times C}$$

(which simply means 1,885 multiplied by the square root of the product of the inductance and capacity) the wave-length range the coil and condenser will give. For example, condenser ·0001 to ·001, and coil, say, 2,000 mhy. = 850 L C to 2,550 L C approx. Next prepare a chart on squared paper (Fig. 103) as follows: Mark off the condenser degrees equidistant on the vertical edge. Start at, say, 900 metres and square the units as follows: 9^2, 10^2, 11^2, 12^2, etc., = 81, 100, 121, 124. 100 − 81 = 19; 121 − 100 = 21. There will be an increase of two in every case after the first number of squares is found; the others need not be worked out. The wave-length scale starts at 900 metres, therefore count 19 squares and mark 1,000 m. from this mark. If 19 squares is too large and half is taken then the increase will be halved.

Calibrating.—When the scale is prepared start the calibrating as follows: Set the receiver to a known wave-length adjustment within the scale or get a station on a known wave that can be relied upon, say G.F.A. on calibration waves. Then listen in on the wavemeter circuit, coupling it closely at first to the C.W. receiver and varying the condenser until a rustling noise is heard, which will be very sharp tuning on the shorter waves. This point will be more quickly found if the aerial terminal of the receiver is tapped with a moistened finger. The clicks heard when a set is oscillating will be heard in the wavemeter when it is

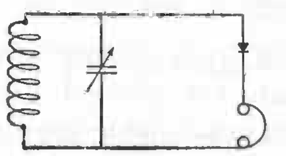

Fig. 102.—Circuit Diagram of Wavemeter.

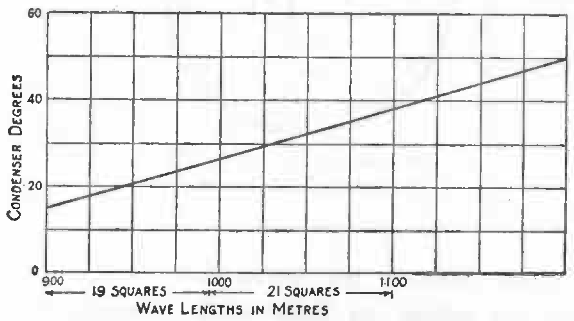

Fig. 103.—Chart for Purpose of Calibration.

in tune and sufficiently coupled. The tuning must be completed without the finger or capacity effect will give a false tune, though the difference is usually small.

The wave-length is marked on the chart at the point corresponding with degrees—wave-length. Two or more such points are plotted and joined and produced, when any wave-length between the limits can be found. To use the wavemeter it is set to the wave-length, and while listening in the receiver is tuned until the hiss is heard ; then transfer on to the receiver and listen for signals. Different values of coils may be used and scales plotted.

If a calibrated condenser is available the chart can be plotted without the aid of the receiver. A buzzer can be used, when the crystal and phones will not be necessary.

CHAPTER XIV

Converting Low-resistance Phones

Meaning of Resistance.—With a few exceptions, it is necessary that the telephone headgear for wireless work be wound to a high resistance, anything from 60 to 4,000 ohms per receiver being general. The statement " high resistance " is perhaps apt to mislead the reader ; what is actually meant, of course, is

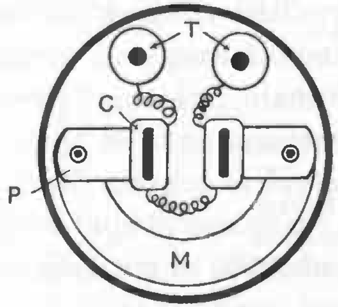

Fig. 104.—Diagram of Interior of Receiver.

that the magnet coils must be wound with a great number of turns of fine wire in order to produce a maximum magnetic effect with very little current. The resultant resistance is, therefore, merely a necessary evil, unavoidable in all magnetic devices which are more or less voltage operated.

Another point about wireless phones is that the diaphragms are much thinner than those used on ordinary commercial telephones. This makes them more sensitive to small variations in the magnetic force from the coils. At the same time, the diaphragms are more easily damaged, an excessive current causing them to buckle.

Construction of Receivers.—The general arrangement of a receiver of the common watch-pattern type is shown in Fig. 104, the ebonite earpiece and diaphragm having been removed. A permanent magnet M of semicircular shape is screwed to the outer containing case, and mounted on the poles are two pole-pieces P, which are bent at right angles and carry the magnet windings C. The ends of the windings are connected direct to the terminals T, which pass through insulated bushes in the metal case and serve to connect the coils C with the main receiving instruments.

The coils C when removed from the ordinary receiver will be found to contain fairly thick wire. The task is to strip them and rewind with much finer wire to a resistance of 2,000 ohms each receiver. Fig. 105 shows the general appearance of the coil when wound, the figures in the sketch corresponding with the reference letters in Figs. 104 and Figs. 106 to 108.

It will be seen that with such a small coil and with only a bent strip of metal P to hold, winding the empty bobbin by hand would be an extremely awkward job ; in fact, it would be almost an impossibility to wind the wire with sufficient evenness to get anything like the required amount on the coils.

Again, the wire being so fine it is necessary to use

great care to avoid breakage, which would mean starting all over again, and also the coil being so small, it would be almost impossible to hold it long enough to get all the wire on at once without the hand becoming cramped.

There are several ways of getting over this difficulty, such as with a winding machine.

Device for Winding.—Perhaps the best method is to use a small electric motor. The arrangement is clearly shown in Fig. 108, E being a small electric 4- or 6-volt motor, using current from an accumulator and having a variable resistance in the circuit to regulate the speed. Clamped to the end of the armature shaft is a circular block of ebonite or fibre B on which the telephone coil C is mounted, being secured in position by means of the clamping screw C S, which passes through the holes in the pole-piece. It will be

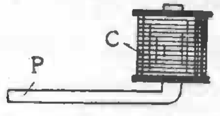

Fig. 105.—Wound Coil on Magnet.

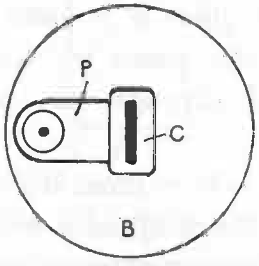

Fig. 106

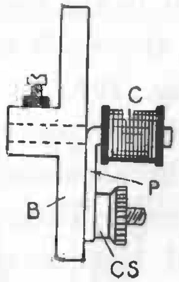

Fig. 107

Figs. 106 and 107.—Magnet and Spool Mounted for Winding.

noticed that the coil C is arranged to rotate as near as possible in the line of the armature shaft, so that, in spite of the coil itself being rectangular in shape, it will revolve with as little wobble as possible. This is very necessary, as any tendency of the coil to revolve eccentrically will tend to break the very fine wire. The ebonite block B is turned up in the lathe and a hole bored through whilst still in the chuck to take the armature spindle; this can either be a good tight fit in the first instance or the block may be clamped on the shaft by means of a small set-screw, shown in Fig. 107. A second clamping screw C S is fitted, to hold the coil C in position for winding. This screw must be accurately positioned to ensure the coil C running true. The best plan is to hold the coil in position and then mark the place for the screw by means of a scriber passed through the hole in the pole-piece P.

Revolving the Magnet.—It is most important that the hole to take the armature spindle be accurately bored, and also that the armature spindle runs true, otherwise the coil C will wobble and difficulty will be experienced, not only in the wire continually breaking, but also in getting it to fill in close to the cheeks of the coil. If the motor E is of the type in which the armature shaft extends at both ends, the opposite end to which the block B is mounted may be used to carry a small knurled knob fitted with a short piece of brass wire about $\frac{1}{8}$ in. in diameter to form a handle. This will prove particularly useful for controlling the motor or for winding portions of the coil by hand.

Winding.—The motor should be connected up to the accumulator and regulating-resistance and tested to see that it is in running order. The block B is then permanently fixed to the armature shaft and one of the coils to be wound clamped in position and trued up. Some fairly thin shellac varnish should be near at hand, together with a strip of silk ribbon, this latter cut to the width of the inside of the coil.

A single layer of silk ribbon is stuck on the core of the coil with shellac varnish, one layer of wire is then wound on and covered with a second layer of ribbon soaked in shellac. The free end of the wire is then carefully brought outside the coil and secured to the clamping screw C S for the time being. It is taken for granted, of course, that the sides of the coil C are already insulated with varnished ribbon or paper; at the same time it is a good plan to stick a small piece of varnished ribbon over the free end of the wire, to insulate it from the subsequent layers of wire

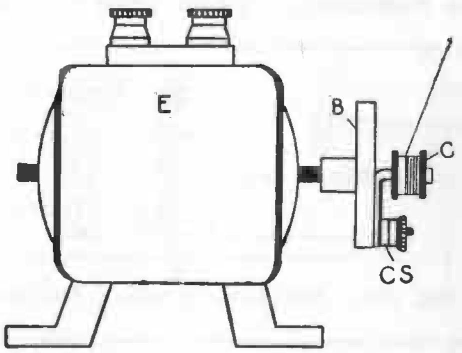

Fig. 108.—Motor with Magnet Mounted.

when these are wound on. The bobbin on which the wire is purchased should be mounted on a small brass rod so that it is free to rotate, and with the wire resting lightly across the second finger of the right hand, the motor should be started on the first speed, gradually increasing the speed of the motor.

If one has access to a gramophone another method of winding is to obtain an empty cotton reel which has a hole through its centre just large enough to fit over the projecting portion of the spindle of the gramophone turntable. Then take the bobbin which

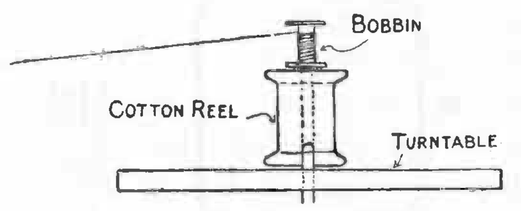

Fig. 109.—Telephone Winding Bobbins.

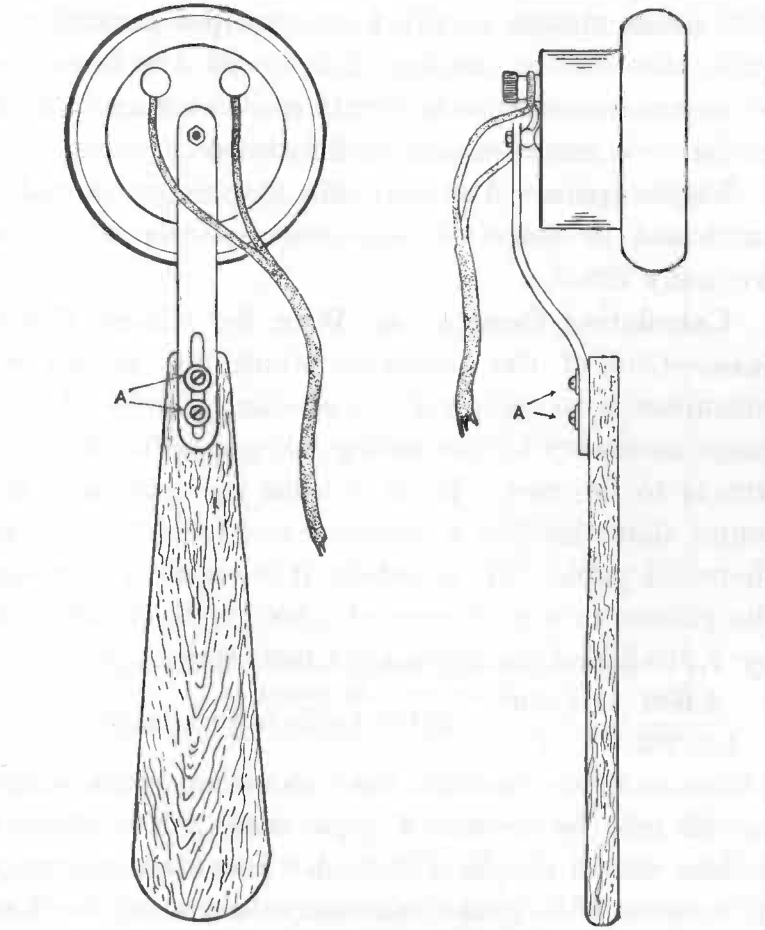
is to be wound and fix it to the top of the reel by means of a spot of glue or sealing-wax. The wire can then be attached to the bobbin and the turntable allowed to revolve as in Fig. 109. The speed at which it revolves can, of course, be regulated by the controller which is fitted to most gramophones.

When the coil is almost full a single layer of silk ribbon should be put on, the last layer of the wire being wound over this, leaving about six turns from the end empty. The top layer is then held in position with the thumb and finger, while an assistant soft-solders a short length of double silk-covered No. 28

S.W.G. wire to the winding. The last six turns will consist of thick wire, when the coil should be covered with two layers of ribbon and the whole thoroughly



Figs. 110 and 111.—Telephones Fitted with Handles.

soaked in shellac varnish and allowed to dry before touching again. The second coil should be treated in the same way.

Assembling.—When both coils are dry they may be remounted on the magnet poles in the receiver case, and the winding connected to the terminals.

Having connected up to the terminals T the whole of the case should be filled with melted paraffin wax up to the level of the top of the coils, the loose connecting wires will thus be firmly embedded and a break in the wire rendered almost impossible.

Diaphragms.—A special thin diaphragm should be purchased in place of the comparatively thick one originally fitted.

Calculating Quantity of Wire for Given Resistance.—One of the problems which the reader will encounter is to calculate the amount of wire of given gauge necessary for rewinding. Suppose No. 42 gauge wire is to be used. From a table of resistances it is found that this has a resistance of 1,910·5 ohms per thousand yards. If, therefore, it is required to rewind the phones to a resistance of 4,000 ohms, divide 4,000 by 1,910·5 and multiply by 1,000, thus :

$$\frac{4{,}000}{1{,}910\cdot5} \times \frac{1{,}000}{1} = 2{,}093 \text{ yards approximately.}$$

This is a better method than calculating the weight, as will now be shown. Copper wire of No. 42 S.W.G. weighs ·14533 lb. per 1,000 yd. To obtain the *weight* of wire of this gauge necessary to rewind to 4,000 ohms the calculation becomes

$$\frac{4{,}000}{1{,}910\cdot5} \times \frac{1{,}000}{1} \times \frac{\cdot14533}{1{,}000} = \cdot304175 \text{ lb.}$$

The difficulty of gauging this amount of wire is at once apparent, apart from the fact that the weight

given does not and cannot take the weight of the covering into consideration.

Testing Phones.—The test commonly used for phones was by means of the handiest and weakest of batteries—a penny and a two-shilling piece, between which a bit of moist paper was placed. The end of one wire from the phones was connected to the " copper," and then the silver coin touched lightly (and repeatedly) with the end of the other wire.

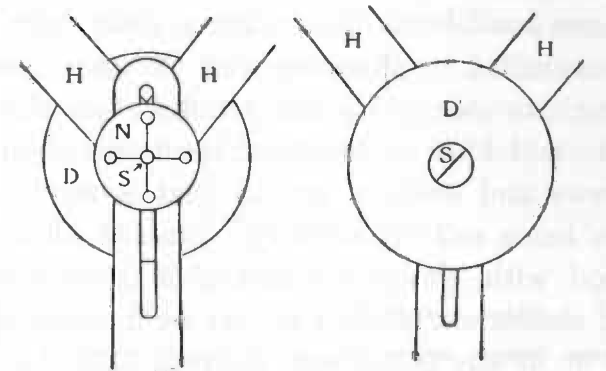


Fig. 112 Fig. 113

Figs. 112 and 113.—Outside and Inside View of Improved Head-band.

Nowadays a similar test is made with a single piece of sheet aluminium, which should be damp. Simply connect one wire of the phone to one end of the aluminium plate, and then touch the plate with the other wire, when, if the phone is properly adjusted each contact will cause a click in the phones.

Another method of testing phones is less difficult and perhaps more efficient than testing by the " weak battery " or sixpence and penny method.

The two leads from the earphones are connected to the two terminals of an ordinary electric bell. No battery whatever is put in circuit. The clapper is pressed forward to the bell and then quickly released. It will vibrate several times before coming to rest. A similar vibration will take place and will be heard plainly in the phones. The explanation of the action is that there is a small amount of magnetism in the magnet of the bell which usually works it.

Handles for Phones.—Ladies often complain of the phone head-band disarranging their hair. This can be remedied by disconnecting the head-band and attaching to short wooden handles, as shown in Figs. 110 and 111. A length of hard dry wood and a few screws and washers are all that is required, the sketches being self-explanatory. Smooth all edges off the wood with glasspaper and give it two or three coats of shellac varnish, or it may be finished in black enamel or in any other way desired. Fig. 110 shows a back view of the phone and link connected to the wooden handle by the screws and washers A, and the side view and general arrangement is clearly shown in Fig. 111. Another method of eliminating the difficulty is to cut out of pasteboard (or other suitable material) two discs 2 in. in diameter. Remove the screws at each side of the head-bands. Pass a screw through the centre of each disc and replace on the head-bands. Fig. 112 shows the outside view, and in this figure D is the disc, H the head-bands, N the nut and S the screw. Fig. 113 (inside view) shows how the attachment shields all moving parts.

CHAPTER XV

The Morse Code

Most owners of crystal receiving sets will be interested in learning the Morse code, for it is interesting to be able to pick up and translate the messages sent between the various ship and shore stations. One excellent method of memorising it is to learn the code in four different groups, the easiest signs being in the first group, which should be learned thoroughly.

First Group.

Fig. 114 shows another method of memorising the Morse code. The code is learnt rapidly simply by visualising the code letters as superimposed upon the alphabetical letters. On thinking of any letter the mind conjures up a mental picture of it and of the dots and dashes of the Morse code lying on it and actually forming part of its shape. The twenty-six letters can be learnt in as many minutes, but only practice, practice, and yet more practice at sending and receiving can make perfect.

There's Money in Knowing How!

Knowing how to do "odd jobs" and repairs, and how to make things for the home, means the saving of expense in many directions. Most men could be "handymen" but lack the necessary knowledge.

"WORK" is a long-established weekly which supplies this knowledge in a simple, straightforward manner. Its articles are full of working details and explanatory diagrams, and are written in simple, non-technical language. Every issue contains several pages devoted to solving, in comprehensive answers, the difficulties of readers.

As a practical guide for the amateur it is unrivalled and unique.

As a mine of information it is inexhaustible.

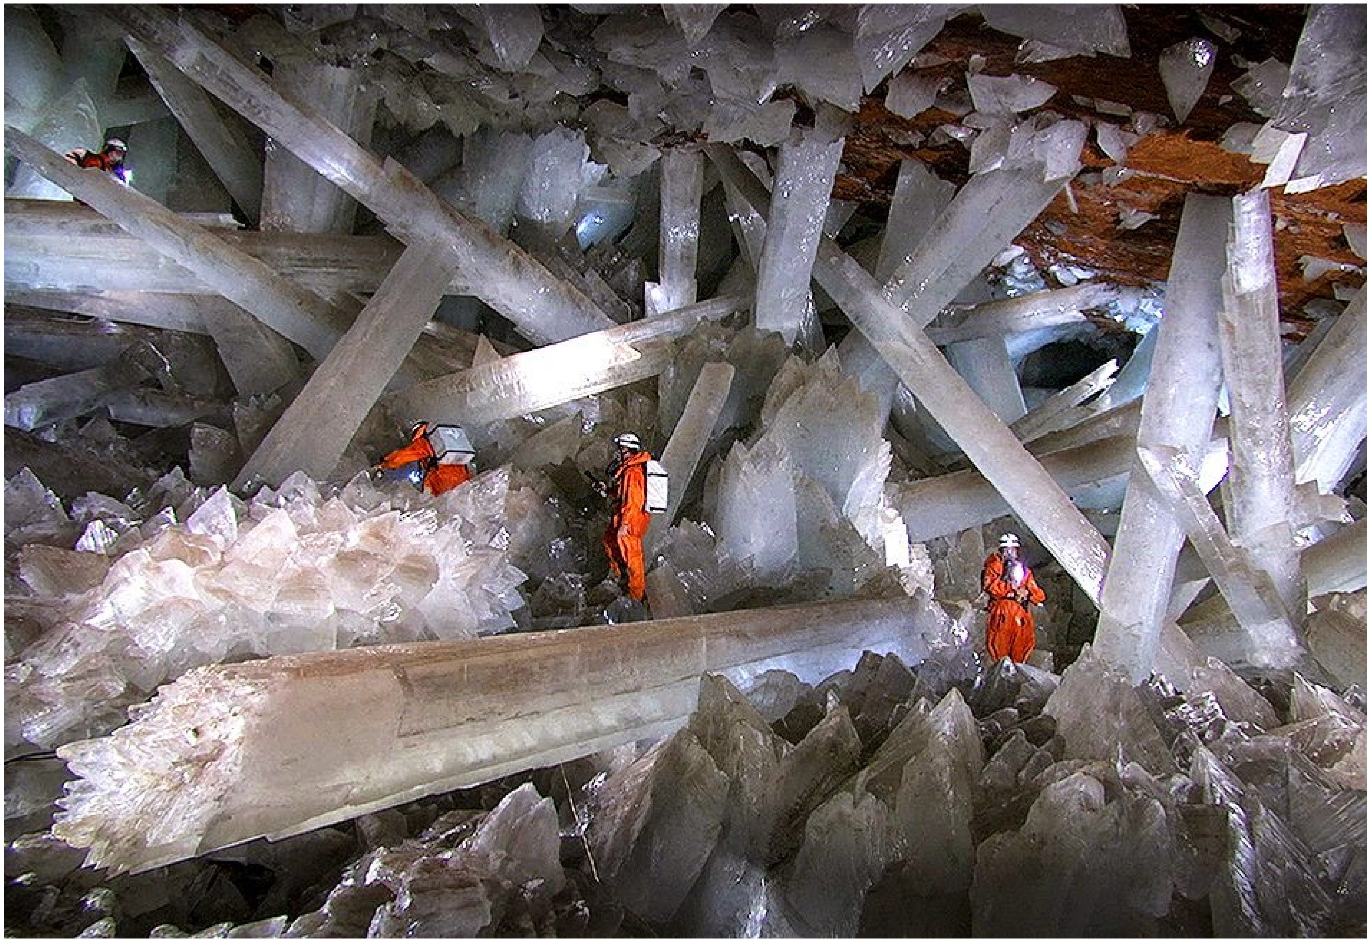
Cave of the Crystals



Cave of the Crystals

The Cave of the Crystals is a natural marvel in Chihuahua, Mexico. Its main chamber houses some of the largest natural crystals ever discovered, hence the name. The magma within makes the cave unbearably hot and humid, and thus it remains largely unexplored.

Nevertheless, this subterranean spectacle is unquestionably one of the world’s most remarkable displays of natural mineral formations.

Cave of the Crystals Map

Cave of the Crystals Facts

The Cave of the Crystals is connected to the Naica Mine, 300m (980 ft.) below the ground in Naica, Chihuahua, Mexico. Despite the Naica Mine having been worked for centuries, the Cave of the Crystals remained undiscovered until the year 2000, when two miners, pursuing traces of silver, broke into the extensive subterranean chamber. Just days later, an iron door was erected in order to protect the entrance.

Whilst the cave is referred to singularly, as the ‘Cave of the Crystals’ (Cueva de los Cristales), it is in fact made up of three co-joined caves, with one far larger than the others.

This gigantic cavern is home to towering stacks of selenite; rising so tall that humans appear miniscule in comparison. In fact, the tallest crystals have been measured at 11m (36 ft.) high, weighing approximately 55 tonnes.

These giant crystals have experienced steady slow growth over the past half a million years. Approximately 2-3 miles (3-5km) under the surface is a giant pool of magma. The caverns became flooded over time as a result of groundwater seeping in. This water was rich in gypsum minerals, and the heat generated by the magma worked like a cooker, maintaining a steady heat for 500,000 years. The gypsum in the water then transformed into the translucent selenite crystals that we see today. Whilst up until now the crystals have grown steadily and slowly, they will grow no further unless the cave floods once again.

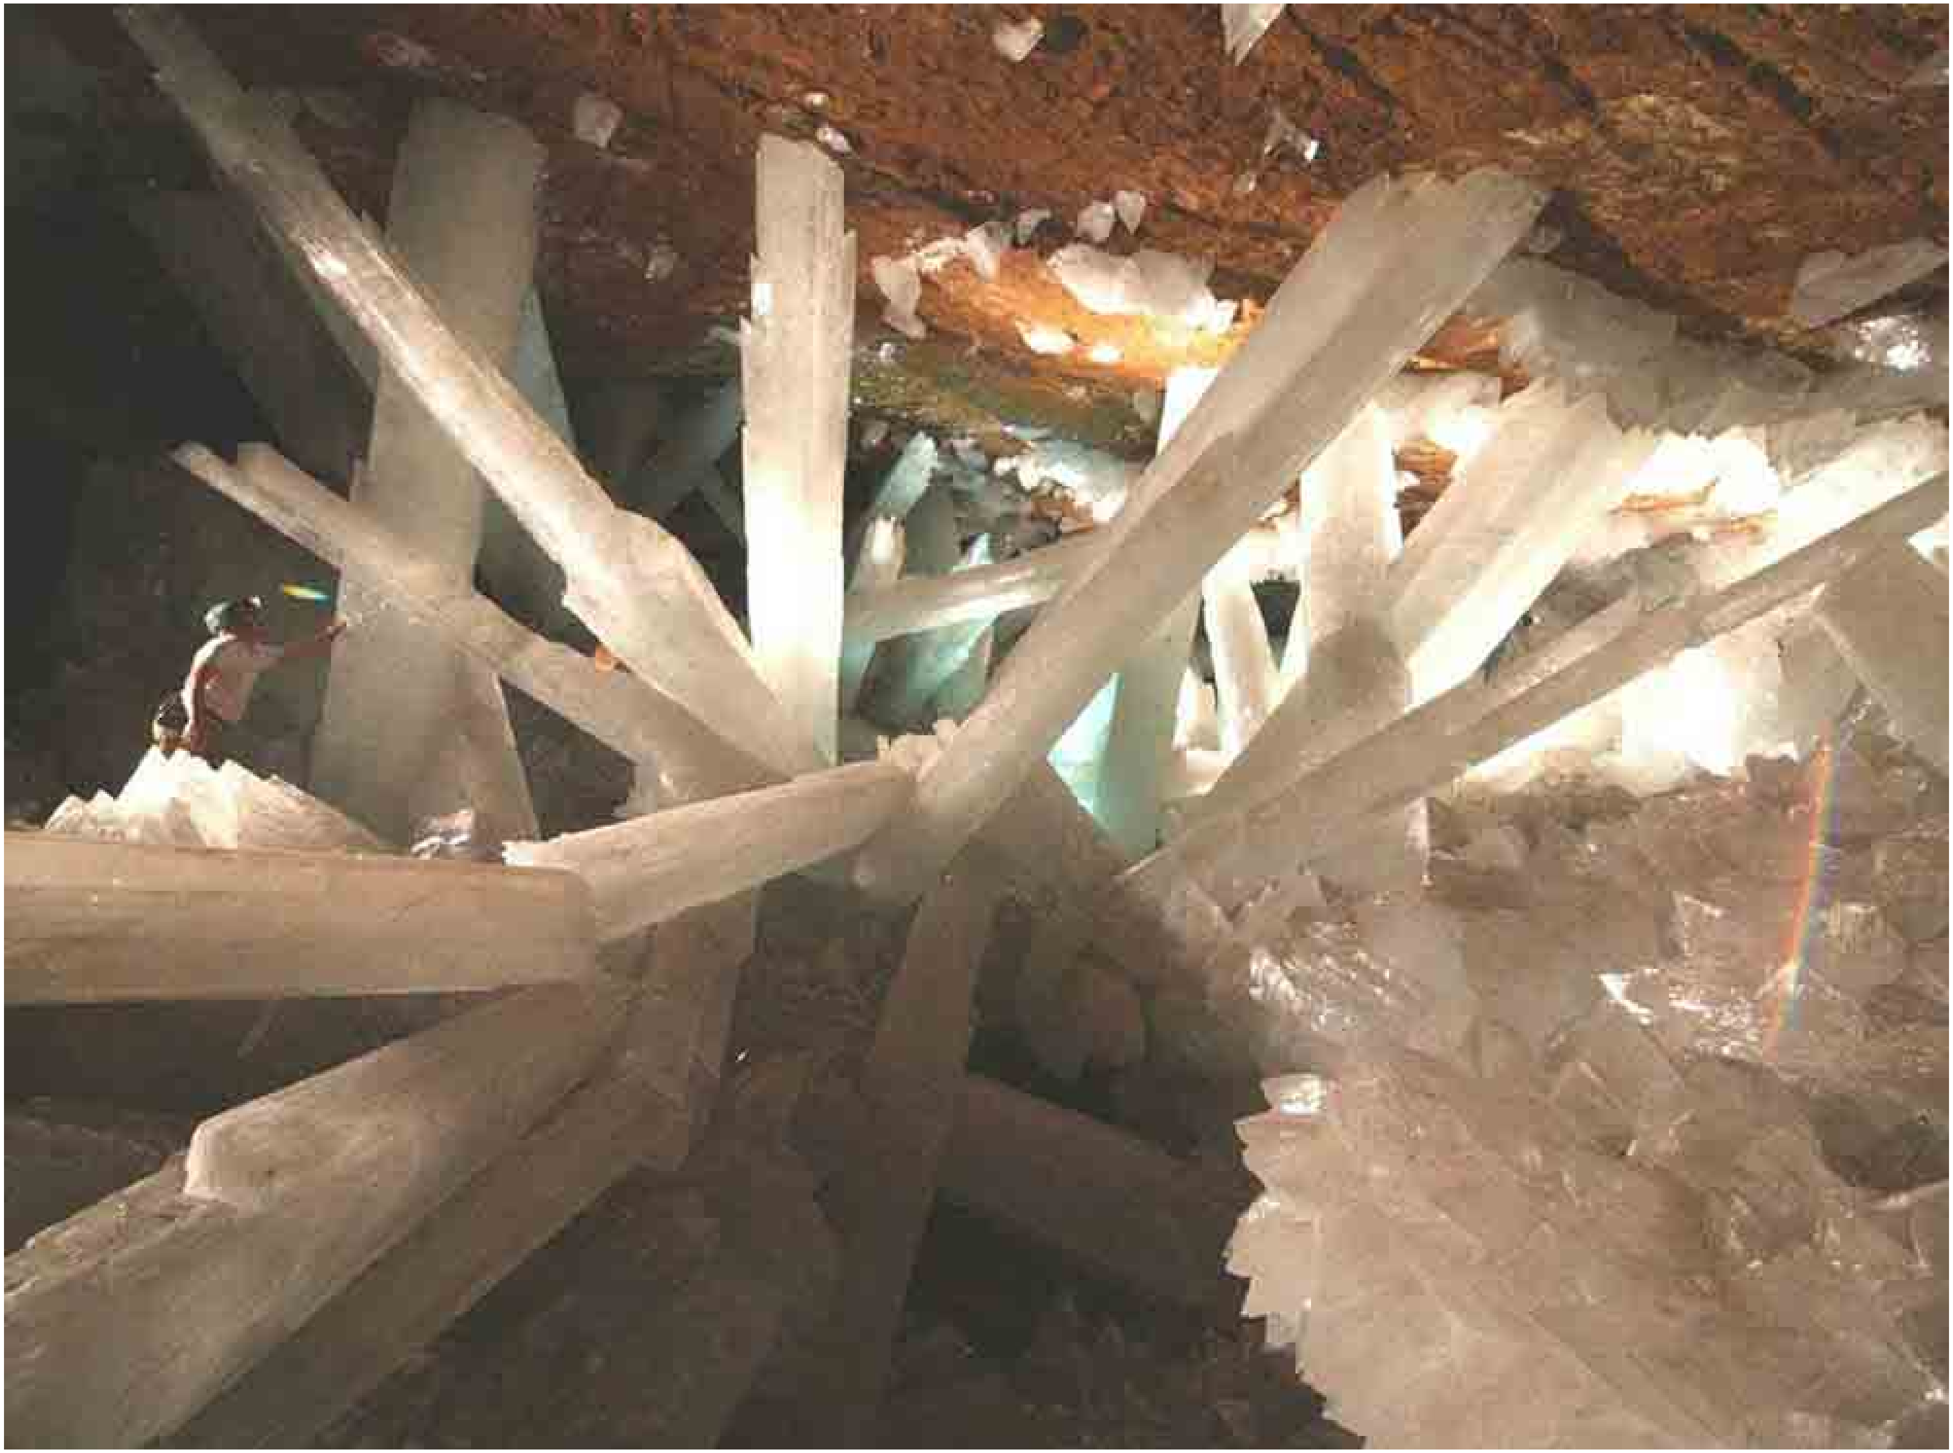
Beneath the cave lies a pool of magma, rising up from the Earth’s core. This heat from this magma makes the cave unbearable for any substantial amount of time. In fact, no human can spend more than a mere few minutes inside the cave. Temperatures of 150°F (65.6°C) have been recorded in the main chamber, whilst the smaller caverns are slightly cooler at 100°F (37.8°C). To add an extra layer of danger, conditions are close to 100% relative humidity.

The story of a miner who managed to bypass the protective iron door illustrates the aforementioned risks perfectly. Despite knowing the risks, he had entered the chamber with plastic bags filled with air. This, he hoped, would buy himself enough time to enter and steal some of the precious crystals within. Alas, the man was found dead the next day; cooked, as though he were food in an oven.

The Naica mine is still active, and should you wish to visit, it is possible to do so with prior approval. However, bear in mind that only the upper caverns are available for access (under supervision), with the lower caverns currently considered too dangerous due to extreme temperatures. Only scientists and employees are able to access these prohibited areas.

BEAUTIFULWORLD.COM

BEAUTIFULWORLD.COM



The Naica Mine of Chihuahua, Mexico, is a working mine that is known for its extraordinary crystals. Naica is a lead, zinc and silver mine in which large voids have been found, containing crystals of selenite (gypsum) as large as 4 feet in diameter and 50 feet long. The chamber holding these crystals is known as the Crystal Cave of Giants, and is approximately 1000 feet down in the limestone host rock of the mine.

The crystals were formed by hydrothermal fluids emanating from the magma chambers below. The cavern was discovered while the miners were drilling through the Naica fault, which they were worried would flood the mine. The Cave of Swords is another chamber in the Naica Mine, containing similar large crystals.

The Naica mine was first discovered by early prospectors in 1794 south of Chihuahua City. They struck a vein of silver at the base of a range of hills called Naica by the Tarahumara Indians. The origin in the Tarahumara language seems to mean "a shady place". Perhaps here in the small canyon there was a grove of trees tucked away by a small canyon spring.

From that discovery, until around 1900, the primary interest was silver and gold. Around 1900 large-scale mining began as zinc and lead became more valuable.

During the Mexican Revolution the mine was producing a great deal of wealth. Revolutionary troops entered the town and demanded money from the owners. One of them was assassinated when he refused to pay, causing the mine to shut down from 1911 to 1922.

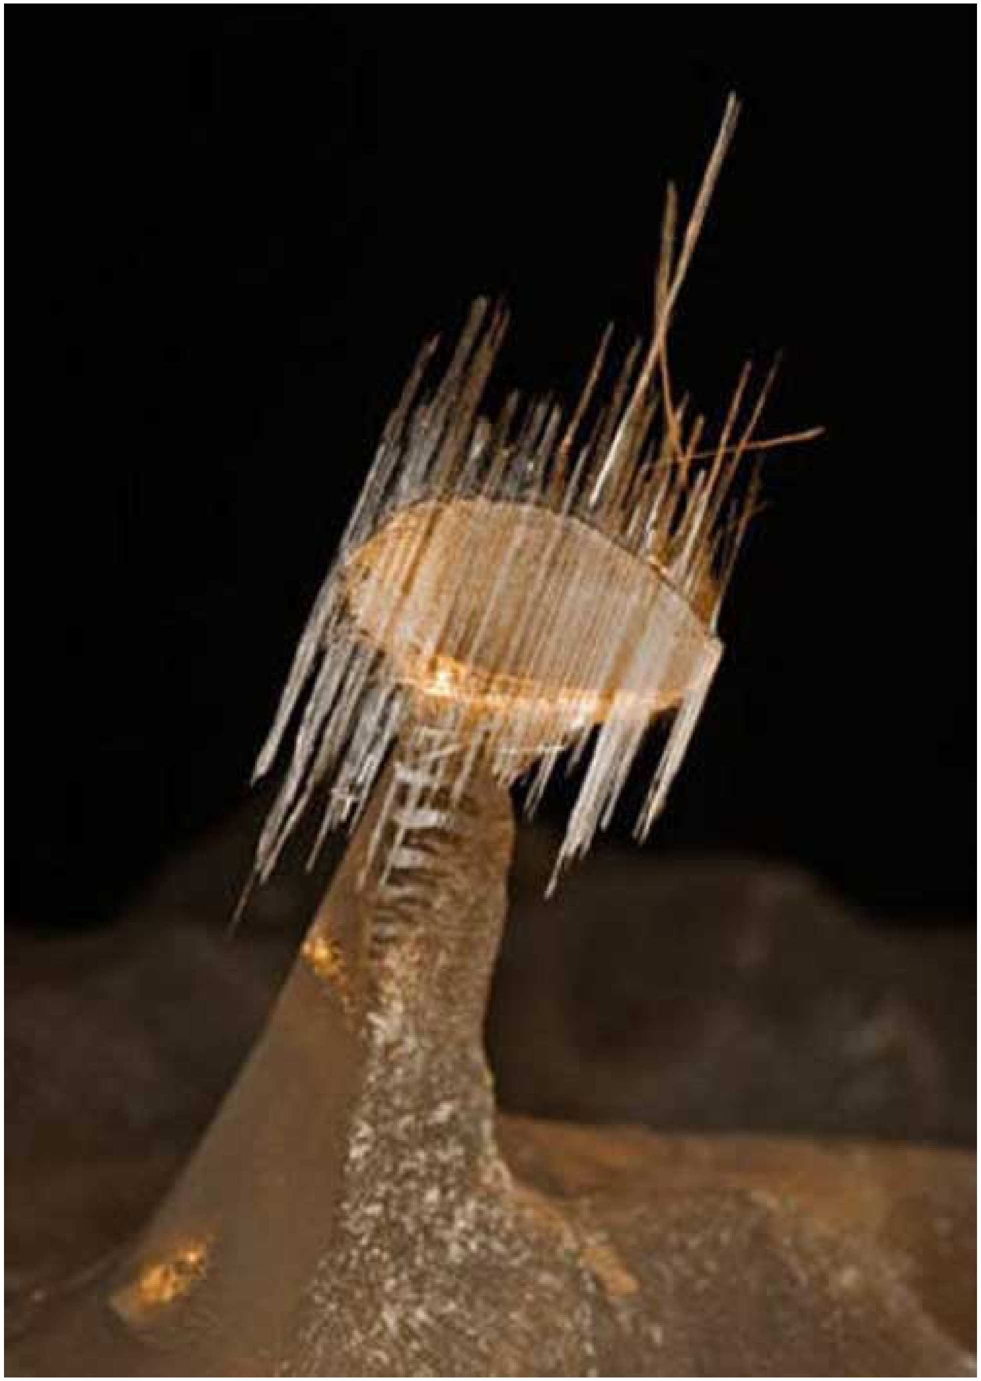
Just before the mine was closed, the famous Cave of Swords was discovered at a depth of 400 feet. Due to the incredible crystals, it was decided to try to preserve this cave. While many of the crystals have been collected, this is still a fascinating cave to visit. In one part there are so many crystals on one of the walls, they appear to be like an underwater reef moving in a gentle undulating motion in an ocean current.

In April 2000, brothers Juan and Pedro Sanchez were drilling a new tunnel when they made a truly spectacular discovery. While Naica miners are accustomed to finding crystals, Juan and Pedro were absolutely amazed by the cavern that they found. The brothers immediately informed the engineer in charge, Roberto Gonzalez. Ing. Gonzalez realized that they had discovered a natural treasure and quickly rerouted the tunnel. During this phase some damage was done as several miners tried to remove pieces of the mega-crystals, so the mining company soon installed an iron door to protect the find. Later, one of the workers, with the intention of stealing crystals, managed to get in through a narrow hole. He tried to take some plastic bags filled with fresh air inside, but the strategy didn't work. He lost consciousness and later was found thoroughly baked.

When entering the cave our group is issued helmets, lanterns, rubber boots, and gloves. One must then be driven by truck into the main mining tunnel called Rampa Sn. Francisco. While the vertical drop is approximately 1000 feet, the drive is almost a half mile long. The heat steadily increases and women have been observed to begin "glowing". The truck stops in front of a concrete wall with a steel door. The intense heat can prevent brain functioning.

At the end of the tunnel there are three or four steps into the aperture of the cavern itself. It is in this short tunnel. In this short distance the temperature and humidity goes from being uncomfortably warm to literally a blast furnace.

Momentarily, the penetrating heat is forgotten as the crystals pop into view on the other side of the "Eye of the Queen". The entire panorama is now lighted and the cavern has a depth and impressive cathedral-like appearance that was not visible on earlier trips with just our headlamps.



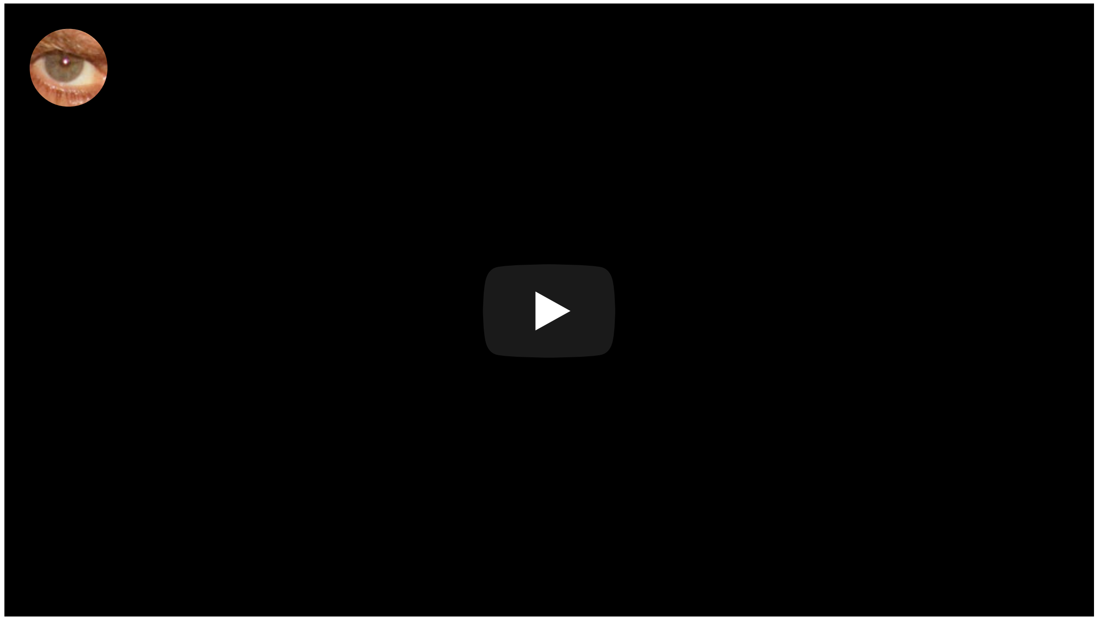
When inside the great cathedral of crystals, the pressure of intense heat create a gamut of emotions and perhaps hallucinations. One can only remain for a short period of time.

Geologists report that these natural crystal formations are incredibly complex, yet so simple. They have a magical or metaphysical personality independent of their chemical structures. There is a magma chamber two to three miles below the mountain and that heat from this compressed lava travels through the faults up into the area of the mine. Super heated fluids carry the minerals the miners are seeking as well as form the crystals. The mine is ventilated; otherwise, it could not be worked. Some parts, however, are not air-conditioned, such as the Cave of the Crystals, and there you feel the heat from the magma deep below. The fluids travel along the Naica fault, enter voids in the bedrock, and then form entirely natural structures that are not easily explained scientifically.

In April 2000, the mining company became confident that the water table on the other side of the fault had been lowered sufficiently to drill.

When they did this, it is almost as if a magical veil of reality was breached and an entirely new world was discovered. Two caverns filled with the Earth's largest crystals were immediately revealed. More discoveries are expected to be made in this magical kingdom of intense natural beauty.

Selenite, the gypsum crystal, named after the Greek goddess of the moon, Selene, due to its soft white light, is said to have many metaphysical and healing benefits. Selenite powder has been used cosmetically for thousands of years to enhance one's natural beauty. It is believed that this crystal assists with mental focus, growth, luck, immunity, and soothes the emotions.



In the News ...

Naica's crystal caves hold long-dormant life BBC - February 20, 2017
Scientists have extracted long-dormant microbes from inside the famous giant crystals of the Naica mountain caves in Mexico - and revived them. The organisms were likely to have been encased in the striking shafts of gypsum at least 10,000 years ago, and possibly up to 50,000 years ago. It is another demonstration of the ability of life to adapt and cope in the most hostile of environments. "Other people have made longer-term claims for the antiquity of organisms that were still alive, but in this case these organisms are all very extraordinary - they are not very closely related to anything in the known genetic databases," said Dr Penelope Boston. The new director of Nasa's Astrobiology Institute in Moffett Field, California, described her findings here at the annual meeting of the American Association for the Advancement of Science (AAAS).

Crystals Break Slow Growth Record Seeker - September 13, 2011
Buried a thousand feet below Mexico's Naica mountain, the "Cave of Crystals" are the slowest growing ever measured. Researchers have measured the slowest crystal growth ever, which created the massive, underground gypsum crystals found in Mexico's Naica mine. Some crystals may have taken as much as a million years to form, growing by the width of a hair each century. The largest crystals in the mine are at 36 feet long and more than three feet across.

Yet another crystal set am broadcast band radio

ralph klimek 2001

Why do I or the world need yet another crystal-set design ?

This little project was motivated by me wanting to show the kids some cool technology. A radio that required no batteries or no source of external power, save that so generously provided by the advertisers of commercial AM broadcast stations. I revived for me rather nice memories of when I was very young trying to coax the last bit of performance from my earliest radios. It was allways a tradeoff between loudness and selectivity. In Melbourne Australia this really only meant being able to discriminate between the government stations at 620 and 770 khz which ran a 50KW transmitter and the more numerous commercial stations between 800 and 1600Khz any only running only 5KW. The meant in practice, being only able to resolve the big government radio and the commercials were reduced to a cacophony all trampling on each other. In those days nearly all the commercials carried horse racing or football on the weekends and this made for amusing listening. Often they would all call the same horse race and you could make out 5 stations at once blabbling out the same race call.

The classic crystal set design that is still taught to kids requires a coil of high inductance, chosen to resonate with what was the standard broadcast gang of 415pF max.

This is actually a rather poor choice. It means a poor Q at the low end and allmost NO Q at the high end, which is why here in Melbourne the commercials could not be discriminated. That meant the "cool" stuff, the pop music and shock jocks could not be heard by me. So I acquired a taste for govenment news and solid classical music. I remember falling asleep while listening to the Week in Business or the haunting sounds of "In Choirs and Places" (radio 3AR) just before nightly close down with one of those horrible crystal earpieces (I called them "infecto-phones") making my ear very sore. But it was worth it because one of those shows in the sixties was the inspiring ABC Weekly Science Report which would lead me on to better things.

So this silly little project caused me to revisit the concept of Q and bandwidth and resonance. The classical crystal set performance was ruined by poor understanding of Q. The classical crystal set inductor has high inductance, presumeably to resonate with a cheap low maximum value variable capacitor. High inductance is not a bad thing if that coil has low resistance, but at RF that is hard to do.

This radio's resonator has very small inductance and very high capacitance. Performance is not limited by the inductors resistance but only by the loading. The load is nothing more that the losses in the antenna and the rectifier. The diode is ,off course, germanium. It feeds a step down transformer, not of audio design, but a mains frequency plug pack transformer which drives high impedance (600ohm) voice coil headphones. Any cheap ones will do. The coil should be wound with the heaviest gauge wire to hand, the ferrite core is optional, it serves merely to shorten the length of wire required and to make the coil size practical. Allthough not done here, the coil should be tapped half way to provide for 2 octaves of tuning. The large tuning capacitance effectively absorbs the capacitance of the antenna.

Now in practice, with an antenna that consists of nothing more than a 10 meter long heavy gauge wire running along the back fence, less than 3 meters above the ground and a good earth, this radio can resolve all of Melbournes' stations with minimal interference. The really suprising thing, it is possible to drive a large diameter loud speaker with this radio. I wouldnt call it loud, but rather, call it noticeable. At late night it could even be described as objectionable!

...and someone else is paying for the power!

	old broadcast gang parrelled to give 900pF Max	Inductor has about 30 to 40 turns of 16 gauge wire

PREFACE

The Publishers make no apology for reviving interest in the crystal set. For too long the technical press has immersed itself in an orgy of complex superheterodyne receivers and television equipment, all of which is necessarily expensive. In the 1920's, crystal set construction was a fascinating and inexpensive pastime indulged in by the majority of boys of that day. Today this pleasurable hobby can be even more attractive, the introduction of the germanium crystal diode and high performance coils, has opened up new paths which will capture the interest of boys of all ages. Perhaps most important of all, not only can a receiver capable of impeccable reproduction be produced without any technical knowledge; but the cost is no greater than that of a few visits to the cinema

INTRODUCTION

Before any attempt is made to construct a receiver, it is necessary to examine the problems which surround the crystal set, so that the best can be obtained from any of the designs attempted.

Firstly, it must be understood that the crystal set as it is to-day does **not** provide any amplification. It relies entirely on what is fed into it via the aerial and earth system and gives a very faithful replica of the original transmission.

From this it will be obvious that the aerial and earth system must be as efficient as possible if the final results are to be in any way outstanding. This because these are the only means by which the signals are fed to the receiver.

Secondly it is necessary to understand the nature of the transmitted signal, then it will be easy to understand the working of the set and to appreciate the function of each of the components.

When crystal sets first became popular, very little information was generally available, at least, not in a form that school-boys could understand.

We all built sets of all shapes and sizes, with coil designs that had to be seen to be believed, but very few of us had much idea of how they worked.

I well remember the case of a cousin of mine who, in those days acquired a magnificent variable capacitor or condenser as it was then called, this instrument had a most impressively engraved dial of polished ebonite, brass vanes and nickel plated end plates. Having observed similar dials on several highly priced commercial receivers in the town, he at once ripped out the somewhat tattered coil from the family receiver and replaced it with this device. The profound silence which ensued caused considerable amazement and dismay until a better informed adult explained the mysteries of L and C to him. Readers of this manual, however, will be better informed and there is no risk of failure with any of the designs described provided the instructions are carefully followed.

The Signal

To commence, we will assume that an orchestra is playing in a broadcasting studio. Since the principle of radio transmission is electrical it is necessary to change the sound produced by the orchestra into an electrical equivalent. This is carried out by the microphone, which picks up the sound and changes it into minute electric currents.

As they appear at the output of the microphone they are too small to be of use and accordingly are passed through a high power amplifier. These amplified currents could now be transmitted, but unfortunately, as we shall learn, owing to the inherent nature of the signal in this state, transmission over any useful distance would be impractical.

When the music from the orchestra is transformed into electrical currents they are in the form of alternating currents, usually called A.C., that is they rise to a maximum in one direction, fall to a minimum, rise to a maximum in the opposite direction and then fall to minimum again. This process is repeated over and over again. One complete rise and fall in each direction is called a cycle and is drawn in Fig. 1. Every time a note is struck on a piano, vibrations are sent out which reach the ear enabling you to hear it. These vibrations are also spoken of as cycles, they rise and fall in intensity the same way as an alternating current. The number of cycles radiated by any given note over a period of one second are referred to as its frequency. Middie C on the piano sends out 261 cycles every second and is known as having a frequency of 261. The microphone also " hears " the note and in the case of middie C produces minute A.C. at 261 cycles. This can be drawn as in Fig. 2, the only difference between Fig. 1 and 2 is, that the time factor is given so that the frequency can be identified. The higher the pitch of a note the higher the frequency and the lower the pitch the lower the frequency. On a piano the frequency of the top note is 3515 cycles and that of the lower 27 cycles. Those of you who have listened to an organ in a concert hall will have noticed that when a very deep note was played, it sounded like a growl to the ear, but the vibrating fre-

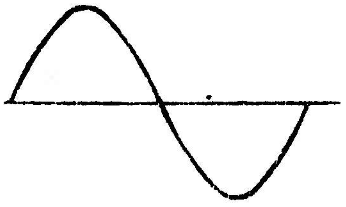

FIG 1

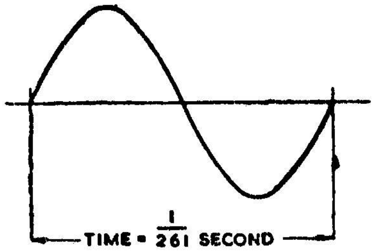

FIG 2

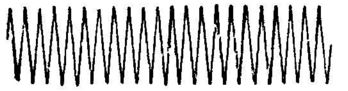

FIG 3

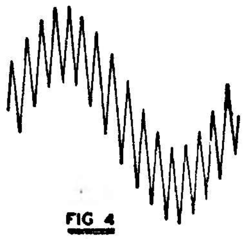

FIG 4

quency could be distinctly felt through the seat. Higher notes have too high a frequency to be observed in this manner.

The range of sounds which can be detected by the human ear are known as audio or low frequencies. From this you will understand that a low frequency amplifier is one which amplifies sound.

So that the transmitter will carry the programme over a useful distance it is necessary to radiate high frequencies. Now, as explained, the programme to be transmitted consists of low frequencies, and to overcome the difficulty, the transmitter generates A.C. of high frequency and combines it with the low frequencies. It will now be understood that the transmitted signal consists essentially of two different parts, a high and a low frequency content.

Fig. 3 gives a representation of the high frequency signal generated by the transmitter. In the case of the London Home Service, the frequency is 908000 cycles.

When referring to a high frequency signal on the medium or long wave-band it is usual to express the frequency in thousands of cycles, thus 908000 cycles becomes 908 kilo-cycles, which in turn may be abbreviated to 908 k/cs. It might at first be thought that by adding the low frequency or L.F. signal to the high frequency or H.F. carrier a form such as in Fig. 4 would result, such a combination is useless, and, so that the original L.F. content can be satisfactorily extracted by the receiver, the L.F. signal must vary the amplitude or output power of the H.F. signal as in Fig. 5.

It is in this form that the signal arrives at the receiving aerial. The aerial in itself is incapable of discriminating between one signal and another, and countless signals will be collected by the aerial at any one time. Many of these are too weak to be of use but the stronger ones must be sorted out since there is no point in receiving several programmes at once.

Fig. 6 shows the basic circuit of the input to a crystal. The coil L possesses a quality known as inductance, and the capacitor C, that of capacitance. If the coil had no capacitance whatever across it, all signals arriving at the aerial would be effectively short circuited to earth. As a matter of interest, it is impossible to obtain this state of affairs since even without any additional capacitor any coil **must** contain a certain amount of self capacitance.

By combining a coil and capacitor as in Fig. 6 a peculiar effect is observed, at one particular frequency, the signals are not short circuited to earth, but are developed across the coil. In other words the combined effect of L and C no longer provides a short circuit, **but only at one particular frequency.** If the value of C is altered the effect will be observed at a different frequency; likewise by altering L the frequency at which the effect will take place can be changed. There is a name for this phenomena, the frequency at which it occurs with any given L and C combination is known as the **resonant frequency.**

The values of the coils and capacitors shown in this manual have been carefully chosen so that resonance will be obtained at all frequencies where stations are broadcasting. Broadcasting stations work in bands of frequencies, those of major interest to crystal set constructors are the medium wave-band 1200 k/cs—600 k/cs and the long wave-band 300 kc/s—150 k/cs.

Usually a variable capacitor is used with a fixed inductance to cover one band and an additional coil switched in to increase the inductance to cover the other. In this way the L and C combination can be adjusted to provide resonance at the desired frequency of any given station. In other words you can **select the** station you want by varying C, that is turning the dial of the variable capacitor. This procedure is referred to as tuning. Having selected or tuned the required station it still remains necessary to change the form of the signal back to that of the original transmission. This process is called detection or de-modulation.

Examination of Fig. 5 will show that the signal has been duplicated, in other words, as it rises in one direction it also rises equally in the other. In this form the signal is useless since each half of the signal cancels the other, and if this signal is applied to a pair of headphones silence will result. Obviously some provision must be made to get rid of the unwanted half of the signal, and it is here that the crystal detector must be considered. This device will pass current in one direction only, ignoring any signal in the opposite direction, so that if the signal of Fig. 5 is passed through such a crystal, that of Fig. 7 will result. There is still the H.F. content to be reckoned

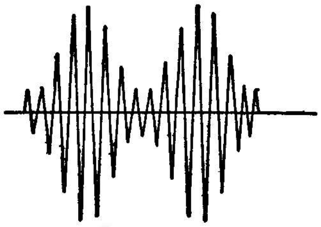

FIG 5

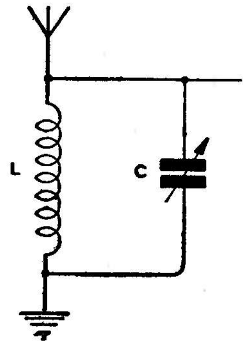

FIG 6

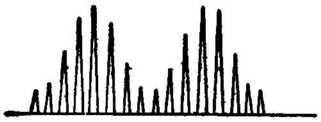

FIG 7

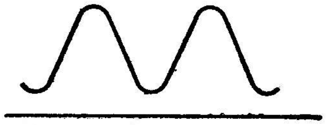

FIG 8

with, fortunately this is easily dealt with, a capacitor connected across the headphone terminals effectively disposes of this, leaving only the audio or L.F. content, as shown in Fig. 8. This audio content, which is a faithful replica of the original transmission is fed to the headphones. These in turn reverse the process of the microphone and transform the electrical currents into sound waves acceptable to the human ear.

Briefly then, your requirements are as follows:—

(1) A good aerial and earth installation, to make the most of the available signals.
(2) A receiver containing:—
  (a) Some form of coil and capacitor (L & C) combination to select or tune in the wanted station.
  (b) A crystal to get rid of the unwanted half of the signal (detection).
  (c) A fixed capacitor across the headphones to get rid of any remaining carrier.
(3) A pair of sensitive high resistance headphones.

Aerials

By this time the intending constructor will be able to appreciate the necessity of a good aerial. It is a point which cannot be over-emphasised. Assuming that you are in the fortunate position of being able to erect an outdoor aerial there are two main considerations, height and length.

One of the best that can be used is the inverted L shown diagramatically in Fig. 9.

It should be erected as high as is practical, every foot counts. The horizontal wire, that is the aerial proper, should have a minimum length of 60′ to which of course the length of the down lead is added. Where it is impossible to erect an aerial with an ideal horizontal length, a compromise must be effected.

Fig. 10 shows a three wire spreader aerial which gives quite a good effective length.

Suitable wire for a receiving aerial will not set any problems, stranded copper about 7/22 gauge is the best. 7/22 means that it consists of 7 strands of 22-gauge wire. This wire may be obtained covered, and for the present purpose is better than the plain or enamelled kind.

Note that insulators are used between the actual aerial wire and its anchoring supports, it is important that these are used, otherwise leakage will occur which will of course spoil its efficiency. Fig. 11 and 12 show how the wire may best be attached to two of the most common types of insulator available. Fig. 11 is of porcelain and is usually referred to as an egg insulator, whereas Fig. 12 shows a more modern (and more expensive) type in glass. If you are using the glass pattern, one is usually sufficient at each end of the aerial, but with the egg type two should be used. No doubt many readers will not be in a position to erect an out-door aerial, and must necessarily be content with an indoor installation.

The next best thing to a good out-door aerial is a replica constructed in a loft. If this form of construction is used, care must be taken when feeding the down lead to avoid close contact with the wall of the house. At the point where the lead feeds under the eaves, a length of rubber tubing can be used to cover the wire. The lead is fed through one of the small spaces left for ventilation purposes. A general idea is given by Fig. 13.

A less elaborate but quite effective aerial can be obtained by using a bed-spring. A length of 7/22 copper insulated wire is connected between the receiver and the spring. The spring should first be cleaned with emery cloth. Remove about 2″ of insulation from the wire and bind it tightly round the prepared spring. The joint may be covered with insulating tape which is obtainable from all electrical stores for a few pence.

Such aerials are quite popular since so many crystal sets are built for bedroom use.

When an aerial is required in the living room, the picture rail can be conveniently used. Insulated screw-eyes are fixed at intervals of about 3 feet along the rail, the wire is firmly anchored to one of them, and stretched right round the room until you arrive back at the starting point. By use of one of the insulated screw-eyes, the wire is secured and the down lead fed to the receiver. The idea is illustrated in Fig. 14.

Soldering

Before leaving the subject of aerials, a few words on soldering will not come amiss. Down leads on outdoor aerials should be soldered, and the same applies to loft types. Apart from aerial leads; earth leads and all the connections in the receiver will require soldering.

For the type of soldering necessary in radio construction an electric iron is the best solution. One of the small types marketed by Adcola or Henleys will be found admirable for the job. These are excellent for actual set construction but are hardly large enough for soldering the down lead to an outdoor type of aerial. Here the heat is dissipated much more quickly and a larger iron is required in order to get the solder to flow.

Ordinary irons which may be heated by a gas flame can be obtained very cheaply from most ironmongers' stores. Assuming the use of such an iron, first heat the iron until the copper bit is giving off a green coloured flame, the iron is now at the correct operating temperature. The bit is now discoloured or oxidised and its tip

should be quickly cleaned with an **old** file which should be kept specially for the purpose. A better idea is to obtain a small block of sal-ammoniac and rub the tip of the hot iron on it. This will clean the tip of the bit perfectly. Next take a length of cored solder such as Ersin Multicore, and melt a little on to the prepared tip faces, now smooth it evenly over the surface with a piece of old rag (be very careful not to burn your fingers) the iron is now "tinned" and ready for use. When heating the iron, be very careful not to let the bit overheat or get red hot, otherwise the tinned surface will be destroyed and the whole process will have to be gone through again.

An electric iron will not overheat, and the tinning will last much longer than with ordinary types, and since the heat does not deteriorate there is less likelihood of making faulty joints.

Having obtained a tinned iron, the process of soldering joints is remarkably simple and anyone with a little patience can acquire the art in a very short time.

To solder two copper wires together: clean the wire with emery cloth, apply a prepared iron and some cored solder to it, the solder will flow evenly over the wire thus tinning it. Repeat the process with the remaining wire and then twist the two together. Now apply the iron to the joint from the underside and the cored solder to the joint on top. Solder will flow evenly over the joint. Remove both iron and solder and allow to set. The solder will harden or set in a few seconds but during this period the joint must not be touched or moved, as otherwise the joint will be "dry" and quite useless mechanically or electrically. On radio components, tags for soldering are already tinned though if they are old, or discoloured it is best to re-tin them. Normally, however, it is only necessary to twist the connecting wire to it and apply the iron and solder as explained.

Remember: **never** apply the solder to the iron and then the iron to the joint, always apply the iron **and** the solder to the joint. It is however a good thing to apply a little solder to the iron tip even when it is perfectly tinned just before making a new joint.

One final "DON'T," you will have noticed that the solder referred to is "cored," that is, it contains resin and other substances through its centre, plain solder as used by electricians and plumbers will not do, as it is the resin or flux

as it is called which makes the solder flow evenly and permits a good electrical joint.

Equally important do not attempt to use a separate flux or soldering fluid with plain solder or to "help" the cored solder; since these are almost certain to cause eventual corrosion and will destroy any components that have been contaminated.

Earths

The provision of a good earth is just as important as the rest of the installation.

Much disappointment would be avoided if this fact were not lost sight of, to avoid any slip up in this direction I am proposing to outline several well tried and efficient earth systems.

If it can be obtained, an earth rod, specially designed for the purpose provides the basis of a good earth connection. These were very popular some years ago when the majority of receivers were either crystal or battery operated, but in these days of modern mains driven sets they are not often used and consequently not always readily available.

Fig. 15 shows how it is used. First excavate a hole to a depth of three feet and fill with a mixture of soot and coke. Drive in the earth rod, which is a hollow copper tube, perforated. The lead to the receiver is connected at the top, and should be of covered 7/22 gauge, as used for the aerial system. Though not obvious it is important that this lead-in should be in covered wire, otherwise a number of indifferent earth contacts are likely to be made at various points along its length until it reaches the set. This is very undesirable and will spoil the efficiency of the system. It is essential to keep the soil surrounding the rod moist, which is one reason why the tube is hollow, and care must be taken to pour water into the tube at intervals.

A very efficient earth is the percolative type also popular at one time. Due to the chemicals used, it will extract moisture from its surroundings, thus maintaining a permanently moist earth.

It should be installed as in Fig. 15b.

The container is of copper or zinc, anything else will quickly rust away, again a good quantity of coke is used. Fill the container with a mixture of sal-ammoniac and coke, and then bury in coke as illustrated. This earth will not require further attention. It is possible to use powdered calcium chloride instead of sal-ammoniac but unless a chemist can be persuaded to make some up it is better to stick to sal-ammoniac.

If a zinc container is not available and you do not use or cannot easily get coke, Fig. 15c should be used. This makes a better earth than many so-called "earths" that I have come across. Obtain as large a tin as possible, make a number of holes as shown. Solder the lead in the bottom and fill it with sal-ammoniac. Replace the lid and bury in the ground. The tin will eventually rust away, but the replacement cost is negligible.

If it is quite impossible to make direct contact with the ground, a water pipe must be pressed into service. This should be a main pipe feeding straight to ground and not a hot water pipe or one fed from a tank. Scrape the pipe clean and twist the lead in tightly around it, a copper clip is even better. Do not attempt to solder on to the water pipe; since cold water is flowing through the pipe, it is extremely unlikely that your soldering iron will heat up the water supply sufficiently to allow a sound electrical joint, though you may spring a leak.

No attempt should be made to utilise gas pipes; the possibility of causing a fire is certainly very remote but, they make incredibly bad earth connections due to a number of joints made before true ground is reached. These joints are at best only semi-conductors, at least from an electrical standpoint.

Headphones

Since the late war there have been a large number of head-phone sets available on the surplus market. These may be roughly divided into two types, high-impedance and low-impedance. For the crystal sets detailed in this book high-impedance 'phones are required and the low-impedance pattern will not be suitable unless a matching transformer is used. As this is likely to cost more than the rest of the installation including the set, it will be as well to avoid them.

High-impedance types have an impedance of 2000Ω to 4000Ω whereas the low-impedance types are usually 600Ω.

The remaining consideration is weight; often cheap headphones are very heavy and uncomfortable to wear, every endeavour should be made to obtain 'phones as light in weight as possible.

Crystals

All the sets shown in this book have been designed to work with modern germanium crystals rather than the older galena crystal.

These germanium crystals require no adjustment, which, in itself, removes the main objection to this class of receiver. Suitable crystals are available from the following manufacturers and on the surplus market: Mullard, G.E.C., Brimar, Westinghouse and B.T.H. They are of robust construction, some in glass, others in ceramic or plastic, but must not be subjected to heavy knocks, otherwise the contact point may become dislodged.

From the information given, you should now be able to install an excellent aerial and earth system, and have some idea of how the crystal set works, so it is time to pass on to the actual receiver construction.

CONSTRUCTION 1

If you examine the following circuits you will find that each one is different. In most cases the difference lies in the coil design and/or the method by which the crystal and aerial is tapped into it. Each of these circuits has its own particular advantage to suit different conditions and the ideal circuit in some localities is not necessarily the best in others. It is not just a matter of a given circuit giving louder results than another, if it were there would be no point in showing more than one.

The main problem is to obtain adequate selectivity without reducing the volume level.

A receiver is said to be selective when it tunes sharply, a set with poor selectivity allows the stations to spread over the dial and when used near a transmitter will receive the local stations mixed together, which of course is useless.

Consider Fig. 16a, this is a very simple receiver, with no special attempt to provide any great amount of selectivity. In areas where signal

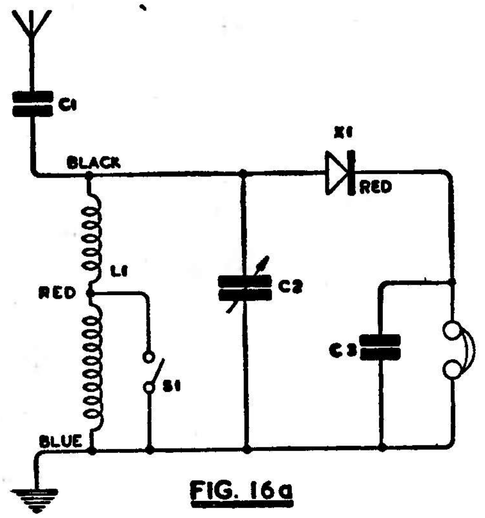

FIG. 16a

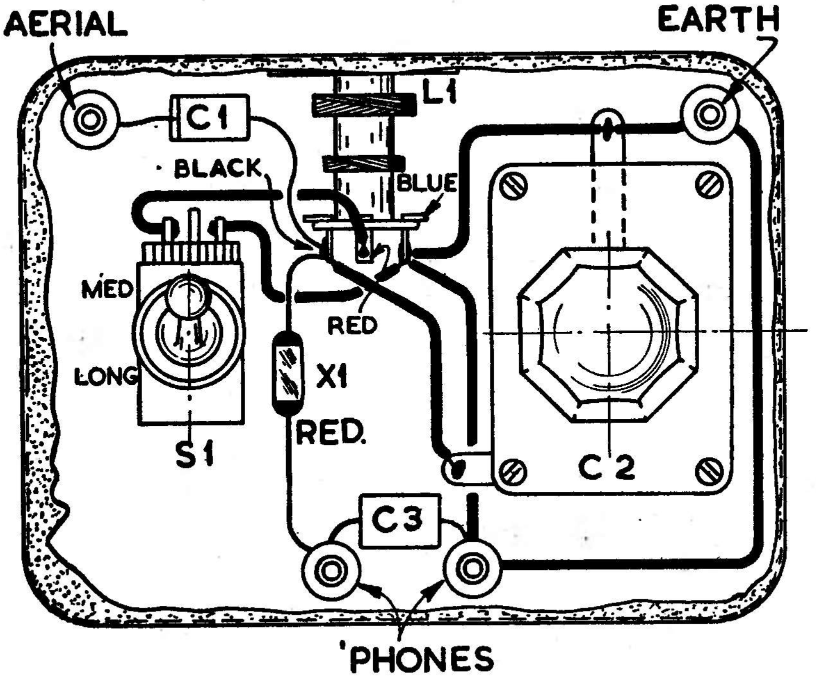

LID SHOWN BROKEN AWAY TO REVEAL POSITION OF COMPONENTS.

FIG 16 b

strength is not high, or a short aerial is used, it will probably be ideal.

It would have been quite easy to increase the selectivity by providing a tap on the coil for the aerial as in Fig. 17a, but unfortunately, as the selectivity is increased overall volume is likely to decrease, so that unless you live close enough to the transmitter to have a large signal available and therefore need the selectivity, the circuit of Fig. 16a will be quite satisfactory.

Capacitor C1 is to prevent the aerial damping the circuit too heavily because this would flatten the tuning unnecessarily, however with small aerials it may be better to take the aerial direct to the black tag on L1. The signals are selected or tuned by L1 and C2, X1 is the crystal and C3 the capacitor across the 'phones to prevent unwanted carrier or R.F. reaching the 'phones.

A practical diagram (Fig. 16b) is provided showing the layout and all the wiring. You will require nuts and bolts to fix the coil, about ½", 4BA size will do, the other parts have locking nuts provided. An old 2-oz. tobacco tin makes a very good container and keeps the size down. Note that the metal box is connected to earth. With the exception of AC/DC receivers the metal work on any receiver or amplifier is connected to earth.

When S1 is open as in the diagram, the set will tune in long-wave stations, but when closed the medium wave-band will be received.

Components List, Fig. 16a

C1	100pF mica capacitor.
C2	500pF tuning capacitor, solid dielectric.
C3	1000pF mica capacitor.
X1	Germanium crystal.
L1	Crystal Set Coil. R.E.P.
S1	Single Pole toggle switch.
4	Insulated wander-plug sockets and plugs.
1	2-oz. tobacco tin (or similar container).

Make sure that the wander-plug sockets are of the **insulated** type, otherwise the metal case will join all the sockets together electrically.

Try to follow the theoretical diagram when wiring, a little practice will soon enable you to wire up a set without a practical diagram, which is a great advantage because often only the theoretical diagram is given when circuits are detailed in the technical press.

Fig 28 on page 34 gives a list of symbols used on the theoretical diagrams, so that you can readily identify the components.

2

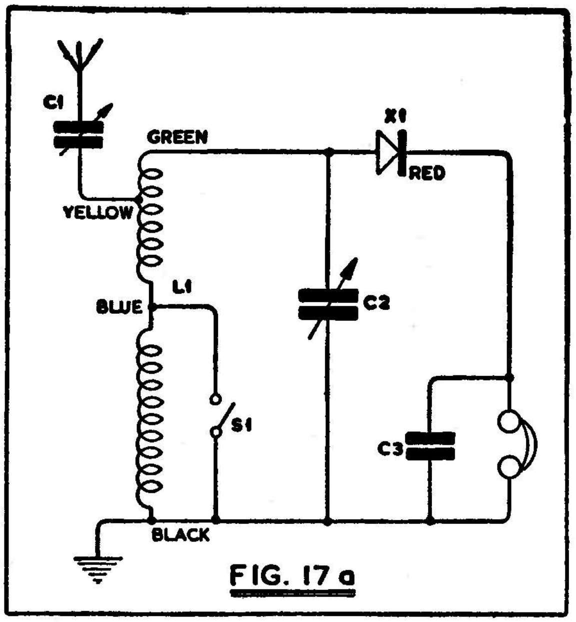

FIG. 17a

Fig. 17a circuit is similar in many respects to that of Fig. 16a. The difference is purely one of selectivity, tuning will certainly be sharper, and even with comparatively inefficient aerials the design will put up a very good performance. There is no reason why the construction should not follow the same lines as the previous receiver but, by enlarging the set a little and using an air spaced tuning capacitor, the efficiency is improved. Observe that the colour coding on the coil, an R.E.P. Dual Range (Blue Box) is different from that of the Crystal set coil used on the previous design, and make sure it is correctly wired in.

C1 is a mica compression capacitor, often referred to as a "trimmer" and because it is adjustable, permits the set to be matched to aerials of varying lengths. Construction is carried out on a square panel of bakelite, perspex or wood, as shown in Fig. 17b. Perspex being clear like glass presents a most attractive finish, provided the set is neatly wired. It must be drilled slowly, however, otherwise the generated heat of the drill will make the hole wander, and spoil the panel.

After the set has been wired and tested a small wooden container can be made to house the completed set.

When carrying out reception tests, a little experiment is well worth while, to get the best out of the set. Try removing the germanium crystal from the green tag on L1 and connecting it to yellow, at the same time removing the lead from C1 to yellow and connecting it to green. Once the best arrangement has been found the wiring can be left permanently in that position. Note that two tags on the coil are unused, this is intentional because on this circuit the extra winding connected to these tags is not required. With the switch S1 closed, the coil will cover the medium wave-band, and when open, long wave stations can be received. It is customary to abbreviate the expression medium wave-band to M.W. and long wave-band to L.W.

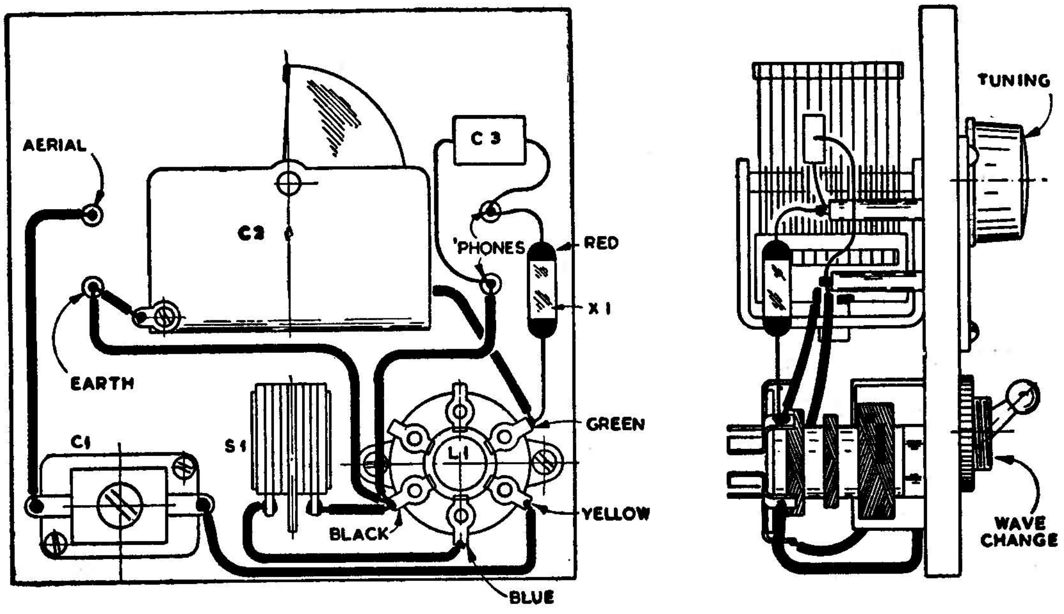

FIG. 17b

3

The design shown in Fig. 18a and 18b is more flexible than either of the preceding sets. That is, it can be varied to suit local conditions to a greater extent than the first two sets. This is made possible by the large number of taps provided on the coil.

You will notice that in this instance the coil is home-constructed on a cardboard former and is much larger than commercially produced coils. Coils wound in this manner are called **solenoids**, the turns are wound on side by side; in this case to a depth of some three inches. The diameter of the coil is made purposely large so as to obtain high efficiency. Modern commercial coils are invariably wave-wound and quite often are litzendraht which is the German for litz wire. This wire is made up of a number of strands of fine copper wire, each strand is enamelled to insulate it from the others, the whole is then silk covered. Litzendraht is more efficient than solid copper wire, and by using this and wave-winding, manufacturers can produce an efficient coil which is also small. Unfortunately wave-wound coils cannot be produced without a complex winding machine and home-constructed coils must take the solenoid form. It would be possible to use litzendraht but it is not easy to obtain by the reel, it is most expensive, and is difficult to handle. This last point is because at termination points, each strand must be cleaned of its enamel before a joint is made, and if one strand is broken, its advantage over plain copper wire is lost. How-

FIG. 18a

ever, by using a former of reasonably large dimensions an efficient coil can be produced cheaply using ordinary copper wire.

The wire must be firmly secured at the start and finish of the windings. Pierce three small holes about ¼″ apart ½″ from the end of the former. Pass the wire through the first from the outside, return it through the second and pass it back again through the third. Leave some 6″ of wire at the end to make off the connection. It will now be possible to wind the turns on tightly without wire slipping.

Count on ten turns and make a loop 1″ long. The method of preparing loops is shown in Fig. 18a, loops or taps should always be made in this manner, never by baring the wire and soldering a further length of wire to it. Carry on with the winding, making off the taps every ten turns as directed until the coil is complete.

Construction is carried out on a wooden base-board and front panel. Secure the coil to the base-board as shown on Fig. 18b, mount the remaining components and proceed with the wiring.

When testing out, it will be found that the further the aerial is tapped down the coil towards the earth end, the greater the selectivity. A position should be found which permits separation of local stations without excessive loss of sensitivity.

The crystal tap is adjusted for best results and different settings of C1 tried out, when choosing the best position for the aerial tap.

FIG. 18 b

4

A most unusual design is reproduced in Fig. 19a.

It first appeared in America about three years ago, and it certainly does offer some advantage over more conventional sets. The tuning circuits are duplicated and two crystals are used, so the circuit may be described as a full-wave receiver. Signals received will certainly be louder than with simple sets, but care must be taken with the coil winding, as with the other receivers using home-made coils, otherwise results will be disappointing. Be very careful to ensure that all three windings are in the same direction, this is very important.

The distance between each winding should be ¼". After the coil has been wound it is a good plan to warm it before a fire and paint the windings with "Durafix." Heating the coils makes the "Durafix" run freely. This substance sets quite hard and there will be no risk of the windings loosening. A small quantity of enamelled wire will cover the requirements of this coil, a 2 oz. reel will provide more than sufficient.

Before wiring in the germanium crystals, examine them carefully, note that one end is coloured red or in some cases marked with a positive sign thus +. You will notice, the sign is the same as the addition symbol used in arithmetic.

It is essential that both the red or positive ends are connected together, note that this is clearly marked on Fig. 19b. The receiver cannot work if

ALL COILS WOUND IN SAME DIRECTION.

FORMER CAN BE BAKELITE, OR WAXED CARDBOARD TUBE.

FIG. 19a

one of the crystals is connected the reverse way round.

A baseboard and panel form of assembly is used for this set which looks quite attractive if housed in a small polished cabinet. Dimensions are not at all critical but Fig. 19b gives a general idea of the layout that should be used. To avoid any unnecessary losses the coil should be mounted on perspex.

Obtain two strips of perspex 5½" long by ½" wide, drill fixing holes at both ends of each strip. It is best to clamp the two together when drilling these holes. Place one strip on the board in position, then put the coil and remaining strip over the first one and screw down. The coil will be clamped neatly and rigidly into position.

Twin socket bakelite strips are used to carry the aerial/earth and 'phone connections, if desired terminals mounted on pieces of bakelite could be used. These socket strips can be purchased from most shops selling components. If feet are not provided, drill two holes and screw into the edge of the base-board. Tag-strips are used to anchor some of the wires from the coil, and the germanium crystals. These also can be purchased for a few pence. At least two tags are necessary on one, and three on the other, though if the strips have more tags than required it is of no consequence. C3-C4, the ganged tuning capacitors have trimmers fitted, this should be stipulated when purchasing, and when first operating the set these small trimming capacitances are set about half-way. The idea of these trimmers is, that they compensate for any difference between the self-capacity of the tuning coils. With the switch S.1 open, that is in the OFF position, turn

in a station at the high-frequency end of the band, that is with the vanes of C3-C4 towards the disengaged position. Adjust C1 for maximum volume, without interference from other stations. Now adjust the trimmers for loudest headphone strength. It may be necessary to run over the adjustments several times for best results. Once they are correctly set, the trimmers require no further adjustment. The tuning coil covers the M.W. band, 1500 kc/s. to 600 kc/s., as the capacitor C3-C4 is advanced and the vanes start to mesh, the frequency to which the receiver tunes **decreases** so that with the vanes disengaged the set is tuned to 1500 kc/s. approximately and at full mesh, 600 kc/s. Switch S1 is used as follows, for stations **lower** in frequency than 850 kc/s it should be in the ON position with the contact closed, but for stations **higher** in frequency, it is in the OFF position. As an example both the London Home Service and London Light Programme transmitters on the M.W. band operate at a higher frequency than 850 kc/s. If any doubt exists as to the operating frequency of a given station, reference should be made to the Radio Times which quotes both wave-lengths and frequency. If you know the wave-length in metres, it is simple to find the frequency. Divide 300,000 by the wave-length in metres, the dividend equals the frequency in kilocycles, i.e., 300,000 ÷ 300 metres=1,000 kc/s. In the same way, dividing 300,000 by the frequency in kilocycles will produce the wave-length in metres.

To use the receiver, tune in the signal by C3-C4, adjust C1 for maximum volume without allowing stations to overlap.

Whenever crystal sets are discussed, constructors are apt to think in terms of medium-wave reception. When you consider that at least 98% of published circuits are designed for this band (sometimes with the long-wave band thrown in as an afterthought) it is understandable. However, if you can provide a good outdoor aerial (and an equally good earth) there is a lot of fun to be had listening to the short-wave bands. This receiver is designed specially for short-wave reception.

A metal chassis is used for construction, these can be obtained ready made in aluminium from most good supply houses. It can be quite small and on the original model a 6″ x 4″ was used. Low loss components are used so as to obtain greatest efficiency on the short wave bands. The coil is a commercial product which plugs into a 4-pin base. Best results were obtained on the 3mc/s to 7mc/s band though coils covering other bands are available.

Note that the tuning capacitor C1 is smaller than normally used and has a maximum capacitance of 140pF.

Coil type 706/R covers the 3mc/s to 7mc/s band, but the set is equally satisfactory on the M.W. band, and to cover this coil type 706P should be used. This coil has an iron dustcore which can be adjusted to make the coil cover the required band. The effect of the core is as if turns were being added or removed from an ordinary coil. When dealing with the short waves it is customary to refer to the frequencies in terms of mega-cycles (mc/s) rather than kilo-cycles. One mega-cycle is equivalent to 1000 kilo-cycles, that is 1,000,000 cycles.

Layout and wiring can be clearly followed from Fig. 20b and a theoretical diagram is shown in Fig. 20a. Care should be taken when arranging a mounting for the aerial terminal. The best plan is to cut a 1″ hole in the chassis, mount the aerial terminal on a piece of perspex and screw into the chassis. This avoids any unnecessary losses between aerial and chassis. The earth terminal is screwed directly into the chassis.

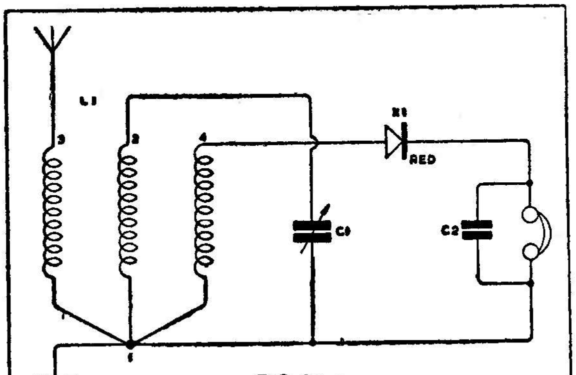

FIG. 20 a

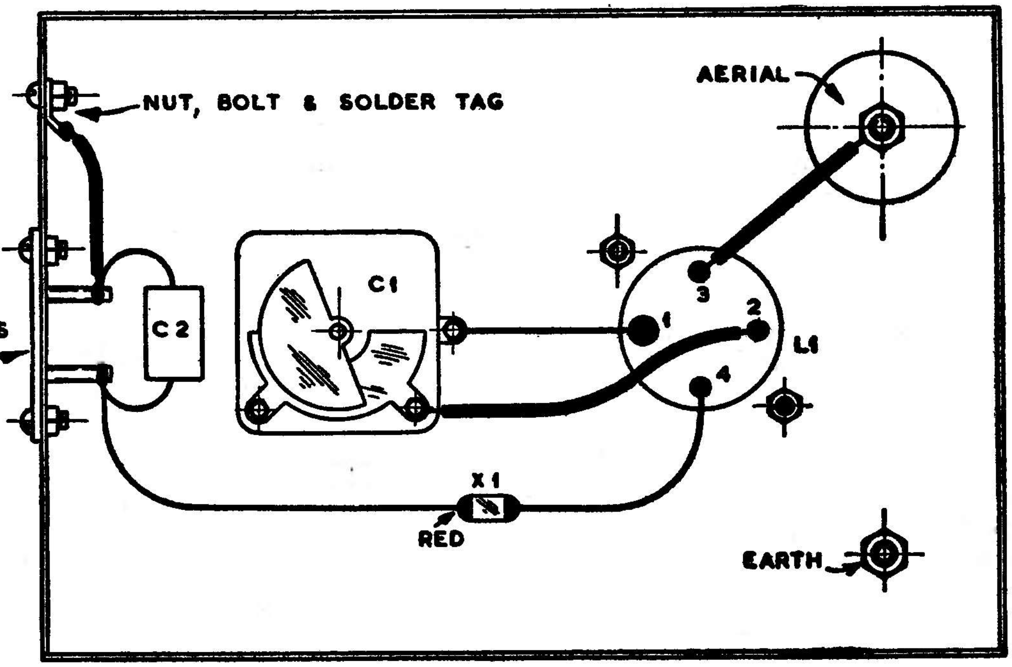

FIG. 20 b

Wiring as shown in Fig. 20a is likely to give the best results, but other arrangements are possible and to get the best out of the set they should be tried.

Refer to Fig. 20a. The aerial is connected to pin 3 on L1, C1 to pin 2 and X1 the crystal to pin 4. If you have a long aerial try this combination—Aerial to pin 4, C1 to pin 2, and the crystal to pin 3. Connections to pin 1 are not altered. In a few cases the following arrangement may prove best. Crystal and C1 to pin 2, aerial to pin 3, pin 4 left free and again pin 1 is unaltered.

Tuning on the short-wave bands is more critical than on the medium waves so tune very slowly over the band and remember signal strength is likely to vary from day to day.

6

Fig. 21a-b is yet another design from America and appeared in Radio Craft some years ago, designed by Mr. W. J. Spain. The original used a silicon crystal which preceded the development of the germanium. Results are certainly very good though of course on the model built here, a germanium crystal was used. Selectivity can be adjusted to suit all conditions and even at short distances from local stations. Good volume can be obtained without the programmes overlapping. Home made coils are used and for best results a 75′ outdoor aerial is desirable.

Baseboard and panel construction is used, which can conveniently be housed in a small wooden cabinet.

Operation is a little more complicated than some of the other designs, but the results certainly merit the extra trouble taken. As with the other receivers much of the success obtainable is due to the coils and these must be carefully made otherwise results will be disappointing.

Layout and wiring can be followed quite easily from Fig. 21b and requires no special comment.

First make the coils. L1 is a tapped coil, the taps should be made in the same way as shown in Fig. 18b. It consists of 90 turns of 22 D.C.C. (double cotton covered) copper wire tapped at the following number of turns, 5, 10, 15, 25, 30, 40, 50, 60, 70 and 80. The former used has a diameter of 2". L2 is also wound on a 2" diameter former, this coil however is not tapped, it consists of 110 turns of 38 D.C.C. or enamelled copper wire. Great care must be taken when handling this wire, it is quite fine and in the hands of the inexperienced will easily break.

After wiring has been carried out the set can be put into operation.

Selectivity is controlled by S2, in position B tuning is broad but in position A it can be quite sharp.

When searching for a station switch S2 to B. Tune the station and switch S2 to A. The frequency range is controlled by the position of the tap on L1, a good plan is to start with the 5 turn tap on L1.

FIG. 21 b

Keep S1 open and C1 for tuning, adjusting the tap on L1 for best results. Very powerful signals are best brought in with S1 closed. When using C1 and adjusting the taps on L1, switch S2 is kept in the A position.

It will be found that C2 acts as a fine control on C1. One division of the tuning dial on C1 is roughly equal to a movement of 20 divisions on C2.

Note that the coils are mounted at right angles to one another and that in this instance wood has been used as far as possible, an aluminium or other metal chassis is not suitable.

7

A very useful receiver for both medium and long-wave reception is possible with the circuit of Fig. 22a-b. A home-made coil is used. On the original a 1¼" diameter former was used but in fact this is not very critical and a 1½" former could be used. An interesting point is the construction of the long-wave coil section. Solenoid coils as used for the medium wave-band are not efficient if the length is too great relative to the diameter. Now as the long-wave section has 300 turns, if wound as a solenoid the winding length would be very great and a lot of efficiency would be lost. To overcome the difficulty the coil is pile wound. If the whole coil were to be wound in one pile it would still be inefficient because of the capacity formed in the winding, but by dividing it into five sections a coil of reasonable efficiency results. The same remarks concerning winding apply to this coil as to all the others in

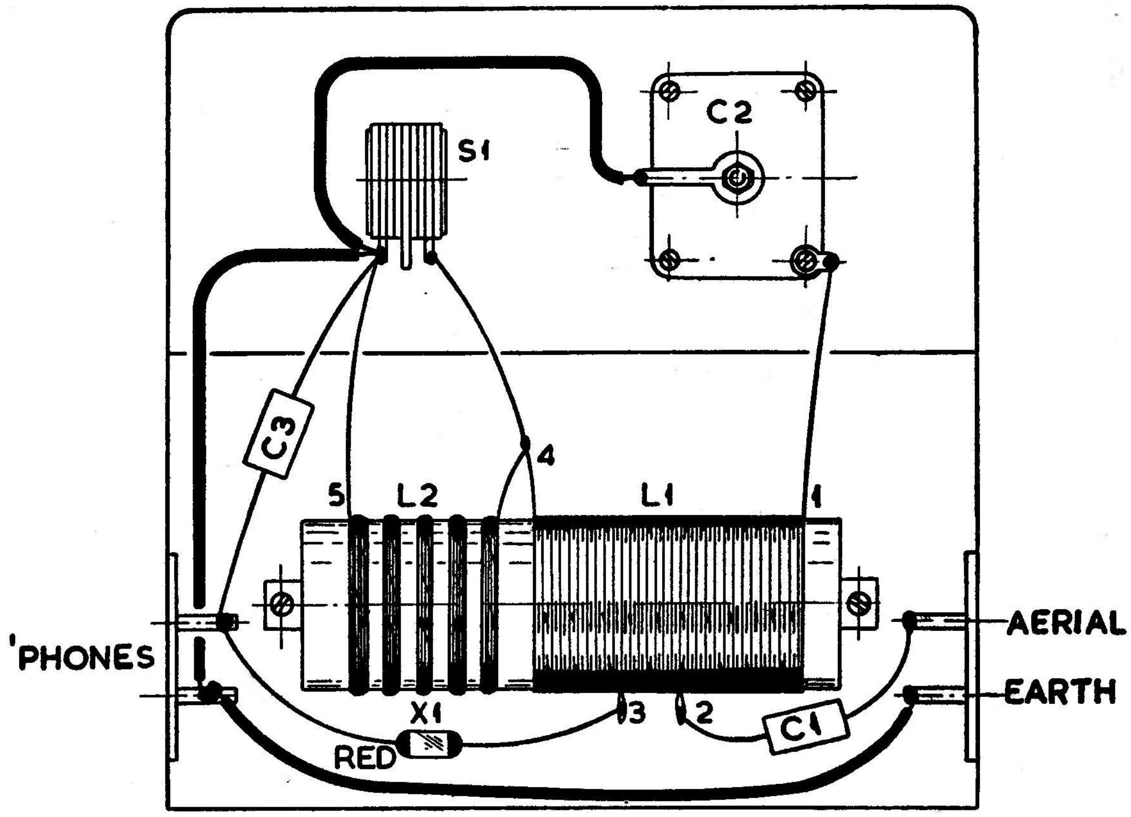

FIG. 22 b

this book, and readers should not, by this time, encounter any difficulties.

The design provides good selectivity with good sensitivity, and provided the set is not required to operate within a few miles of a powerful transmitter, no trouble will be encountered from interference between adjacent stations.

A wooden base-board and front panel is best for this design, and the wiring and layout can be clearly followed from Fig. 22b. Switch S1 is open for long-wave reception and closed for the medium-wave band.

Coil mounting can be on the same principle as for the full-wave design Fig. 19a-b.

8

If you look at all the other circuits shown in this book you will find that in each case the tuning capacitor and tuning coil are in parallel, this is by no means essential and the circuit of Fig. 23a shows a series arrangement that is the tuning capacitor is between the coil and earth instead of being wired up across it. This design also appeared in **Radio Craft** a few years ago.

An interesting point is that the coil is a conversion adapted from another type of component. To make this coil you must obtain an old I.F. transformer as used in superheterodyne receivers.

You will require one designed to work anywhere between 450 and 470 kc/s. Some of the very early ones worked at 110 kcs/ but these are unsuitable.

The I.F. transformer must also be of the type tuned by an iron dust core at each end.

Dismantle the transformer, remove the parallel capacitors and mounting wires so that you are left with two coil bobbins and their former. Be very careful when un-soldering the wires from the supports because the coils are usually wound in litzendraht and must remain intact. Remove 25% (approximately) of the turns from one coil which we will call the secondary, and completely remove the iron dust slug from this coil, now cut the former in half, and mount as in Fig. 23a. Warm the coils with heat from your soldering iron or from a fire and gently slide the coils into position at the ends of the former as in Fig. 23a. The wax will set again holding the coils in their new position.

Note that the wires from the coils are connected to tags on the mountings. These are pieces of bakelite, and usually the original end pieces used on the I.F. transformer can be used.

A word about soldering litzendraht. Do not attempt to use emery paper. Prepare the end of wire by removing the outer silk covering and dip the end in methylated spirits. Ignite with a match and after about five seconds wipe with a cloth held between finger and thumb. This will quench the flame and will remove all traces of enamel from the wire. It is a good plan to experiment with the odd length of wire removed from the secondary coil. If the coils prove to be constructed of ordinary copper wire, it can of course be prepared with fine emery cloth in the normal manner.

Components List, Fig. 23a

C1	500pF variable capacitor.
X1	Germanium Crystal.
L1	See Text.
4	Plugs and sockets or terminals.

Wiring is straight forward as can be seen from Fig. 23b and requires no explanation.

Operation is as follows, selectivity is controlled by varying the distance between coils with the wing nut, and to an extent by the position of the primary iron dust core. Remember that the aerial and earth installations are as important with this set as with any other crystal receiver. No parallel capacitance appears necessary across the 'phones, the set works quite happily relying on the self-capacitance of the head-phones.

FIG. 24 a

Most enthusiasts like to build their own coils but when it is a question of something really small combined with efficiency a commercial coil is the obvious choice.

Fig. 24a-b uses a tobacco tin or a similar container just as the design shown in Fig. 16a.

This receiver however is a little more selective and is more suitable than the earlier design, if you are near a transmitter or have a very long aerial. Take great care to connect the coil according to the colours shown on the diagrams. Sockets are used for wave-changing, this cheapens the cost a little and they are just as efficient.

10

In certain cases, signals from the local transmitter are too powerful to permit a crystal set with a normal coil to be of much use. I myself live in Hertfordshire a few miles from the London transmitters, and find a more elaborate circuit is necessary. Now in radio circles it is a well-known fact that the greater the number of tuned circuits, the greater the overall selectivity. Look at Fig. 25a, you will see that the usual L and C tuning arrangements have been duplicated. This type of circuit is known as a Band-Pass Filter. There are many kinds of such filters, this particular type is an inductively-coupled filter, note that energy from the first half (L2) is conveyed to L3 by way of two small inductors L1 and L4.

Tuning is quite sharp and the "feel" of the set is quite different from that of single coil designs. A small chassis is ideal for construction. 6"x4"x2½" was used on the original, though it could have been smaller.

Fig. 25b gives the layout and wiring.

Take particular notice that L1-2-3 is mounted horizontally and at right angles to L4-5-6, this is to prevent the coupling from being too "tight" which would ruin the idea of the filter. A good aerial and earth is of course necessary. It may be found on test that the selectivity is too great

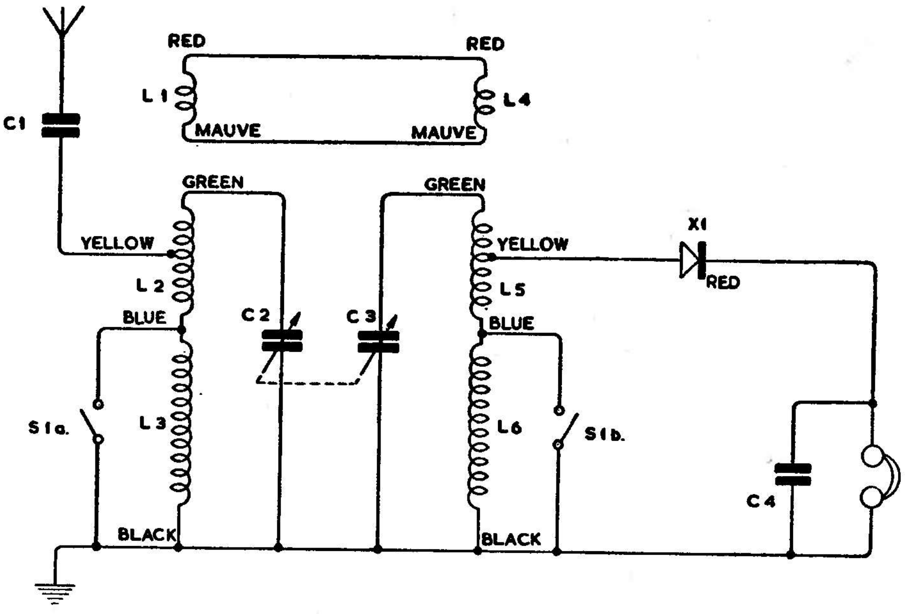

FIG. 25 a.

and that volume has suffered. This can be ingeniously overcome by connecting a very small capacitance between the two Green tags on the coils. The simplest way is to connect it across the fixed vane connections on C2-C3. Values for this extra capacitance are a matter for experiment usually a value between 10pF and 47pF is sufficient. A small 50pF trimmer could be used and adjusted to suit. The ideal setting is to enable powerful adjacent stations to be received just short of overlap so that as much volume as possible is obtained.

There is one point to be observed with the ganged capacitor. It should be of the type fitted with trimmers though of course, there is no reason why you should not fit them yourself. These are to allow for differences between coils to be balanced out, and consist of a small variable capacitance across each main section.

When setting up the receiver, first set each trimmer at half way and tune in a station near the high-frequency end of the band (vanes nearly out) adjust the trimmers for maximum volume. If extra coupling capacity is added as described, try adjusting them further.

Once properly set up, no further adjustment is necessary.

Another band-pass circuit is shown in Fig. 26a. This time home-made coils are used. This filter is not inductively coupled but entirely capacitive, relying on C3. As in the previous circuit it must be adjusted to give just sufficient " broadness " to the tuning to provide adequate volume without station overlap. To avoid unwanted coupling a screen is mounted between the coils, this is necessary because due to the size of the coils they would be bound to couple quite tightly without it. Such precautions were not necessary with the circuit of Fig. 25a, as the commercial coils are much smaller physically and the risk of unwanted coupling reduced.

The coils for this receiver are for medium wave reception only, this keeps the size down. Coil winding procedure has already been fully explained, and covers all the requirements of these coils. Base-board and panel construction is used, and for more accurate tuning since the coils are home-made, separate tuning capacitors are recommended. Fig. 26b gives the layout and practical wiring.

X1	Germanium Crystal.
4	Terminals or plugs and sockets.

For those who do not wish to bother with these a ganged capacitor can be used, but tuning may not be as good as with separate ones. The screen mounted between the coils is of aluminium or copper and should be about 1″ higher than the coils and the same length as the baseboard depth.

FIG. 26 b

12

Fig. 27a-b uses a band-pass filter for tuning, and the coils are home-constructed.

With this design a ganged capacitor is quite suitable as the coils tune quite accurately. It is essential that the coupling condenser C3 is **non-inductive,** there will be no difficulty in obtaining a new component of this pattern but it is as well to avoid old components which may not employ this form of construction.

Receivers using this type of filter are used to the best advantage when situated a short distance from a powerful transmitter and if selectivity is not important this particular design is not the most suitable.

Both medium-waves and long-waves are catered for: consider L1-2-3, this is the first half of the filter.

L1 is the aerial coupling coil, with S1 closed, the medium-waves are received. This coil is inductively coupled to L2 and L3. Again with S2 open L2 and L3 combined cover the long-waves and when S2 is closed the medium waves are covered.

Tuning for this half of the filter is by means of the capacitor C1, which is one half of the ganged capacitor. A screen is erected between the two sets of coils comprising the filter, and coupling is effected by C3, an earth return for the coils is provided by R1.

L4 and L5 operated in a similar manner to L2 and L3, tuning is by means of C2, the remaining section of the ganged capacitor. You will realise that the coils must be accurately wound otherwise tuning will not remain constant between the two sections over the band.

The ganged capacitor should be fitted with trimmer capacitors when purchased so that the two circuits can be balanced.

You will have noticed that this circuit uses three sets of switch contacts. A three-pole two-way wafer switch is the best choice otherwise either two or even three separate switches are necessary. All the necessary coil details are given in the diagrams, the tap on L4 is made in the same way as shown for other coils in the manual. One other component used only on this design, is the resistor R1, its size is not important because the current flowing is so small it can be ignored.

A ¼ watt rating is adequate, its precise value is not critical so that a 20% tolerance component is quite suitable.

Resistors are coded by colours and the 1000Ω type you require will bear the following sequence. At one end will be painted three coloured rings.

SYMBOLS USED IN THE CIRCUITS DESCRIBED.

FIG. 28

The first one is BROWN which represents 1, the first figure of the value, the second BLACK, this indicates the second numeral is nought, and the third colour is RED which tells us that two further ciphers or noughts are added to give the total value. From this you can see, we have 1 plus a nought equalling 10, plus two further noughts which total 1000. Some earlier types of resistor were painted differently, the whole body colour represented the first figure, one tip was coloured to represent the second figure, and a painted dot in the centre gave the number of ciphers to be added.

There are no other special points regarding construction except perhaps that if a long aerial is used, a small 100pF capacitor might be tried in the aerial lead to prevent damping the first tuned circuit.

When setting up the receiver, tune to a station at the high-frequency end of the M.W. band and set the trimmers for loudest volume, no other adjustments are necessary.

CONCLUSION

The twelve receivers described are representative of the best crystal set designs available to-day. Their construction will provide many hours of useful enjoyment, and the results will give lasting pleasure.

A final word about components, if no actual maker is specified, any good class component can be used. Switches, fixed and variable capacitors and crystals, are available from numerous manufacturers all of which are invariably of excellent quality. Where a particular manufacturer's product is called for, the specification should be adhered to. The commercial coils specified are freely available from most supply houses specialising in components for constructors, but in case of difficulty write to Bernards (Publishers) Ltd., The Grampians, Western Gate, London, W.6, who will, on receipt of a S.A.E. be pleased to supply the address of your nearest stockist. Coil formers are not always easy to obtain and in this case advice should be sought from Post Radio Supplies, 395, Queensbridge Road, London, E.8, who will be pleased to help in any way possible.

[57] ABSTRACT

A new alternating current process and system for treatment of blood and/or other body fluids and/or synthetic fluids from a donor to a recipient or storage receptacle or in a recycling system using novel electrically conductive treatment vessels for treating blood and/or other body fluids and/or synthetic fluids with electric field forces of appropriate electric field strength to provide electric current flow through the blood or other body fluids at a magnitude that is biologically compatible but is sufficient to render the bacteria, virus, parasites and/or fungus ineffective to infect or affect normally healthy cells while maintaining the biological usefulness of the blood or other fluids. For this purpose low voltage alternating current electric potentials are applied to the treatment vessel which are of the order of from about 0.2 to 12 volts and produce current flow densities in the blood or other fluids of from one microampere per square millimeter of electrode area exposed to the fluid being treated to about two milliamperes per square millimeter.

FIG. 19

ALTERNATING CURRENT SUPPLIED ELECTRICALLY CONDUCTIVE METHOD AND SYSTEM FOR TREATMENT OF BLOOD AND/OR OTHER BODY FLUIDS AND/OR SYNTHETIC FLUIDS WITH ELECTRIC FORCES

FIELD OF INVENTION

This is a continuation-in-part application of prior U.S. patent application Ser. No. 07/562,721 filed Aug. 6, 1990, now abandoned

This invention relates to novel electrically conductive methods and systems employing electrically conductive vessels provided with electrically conductive surfaces for use in subjecting blood and/or other body fluids and/or synthetic fluids such as tissue culture medium to direct treatment by alternating current electric forces.

BACKGROUND PROBLEM

It is now well known in the medical profession and the general public that blood collected in a blood bank from a large number of donors may be contaminated by contaminants such as bacteria, virus, parasites and/or fungus obtained from even a single donor. While screening of donors has done much to alleviate this problem, the screening of donors can and does miss occasional donors whose blood is unfit for use. When this occurs and the unfit blood is mixed with otherwise usable blood, the entire batch must be discarded for transfusion purposes. Because of this problem, the present invention has been devised to attenuate any bacteria, virus (including the AIDS HIV virus) parasites and/or fungus contained in blood contributed by a donor to the point that any such contaminant is rendered ineffective for infecting a normally healthy human cell, but does not make the blood biologically unfit for use in humans. Similar problems exist with respect to treatment of other body fluids, such as amniotic fluids. The treatment method and system is also applicable to mammals other than humans.

In addition to the above, there is a need for methods and systems for the treatment of blood and other body fluids both in in-situ processing wherein the treated blood and/or other body fluids are withdrawn from the body, treated and then returned to the body in a closed loop, recirculating treatment process that is located near but outside the patient's body, or the treatment can be effected through implanted treatment system components.

In co-pending United States application serial No. 07/615,800 entitled "Electrically Conductive Methods and Systems for Treatment of Blood and Other Body Fluids with Electric Forces"-Steven Kaali and Peter M. Schwolsky, inventors, filed concurrently and co-pending with this application, a similar treatment method and system employing direct current excitation potentials is described and claimed. The disclosure of co-pending application Ser. No. 07/615,800 hereby is incorporated into this application in its entirety.

SUMMARY OF INVENTION

The present invention provides new electrically conductive methods and systems using alternating electric current excitation potentials for treating blood and/or other body fluids, such as amniotic fluids, and/or synthetic fluids such as tissue culture medium from a donor to a transfusion recipient or to a storage receptacle, or for recirculating a single donor's or patient's blood or other body fluids. The treatment can be accomplished in a treatment system external of the body or by implant devices for purging contaminants using a novel electrically conductive vessel for direct electric treatment of blood or other body fluids, such as amniotic fluids, with alternating current electric field forces of appropriate electric field strength to attenuate such contaminants to the extent that bacteria, virus, fungus, and/or parasites contained in the blood or other body fluids are rendered ineffective to infect and/or affect normally healthy human cells. The treatment, however, does not render the blood or other body fluids biologically unfit for use in humans or other mammals after the treatment. The new methods and systems according to the invention achieve these ends without requiring time consuming and expensive processing procedures and equipment in addition to those normally required in the handling of blood or other body fluids or synthetic fluids. The invention can be used to achieve the electric field force treatment during the normally occurring transfer processing from a donor to a recipient or to a collection receptacle, or recirculation of a single donor's or patient's blood or other body fluids, such as amniotic fluids.

BRIEF DESCRIPTION OF DRAWINGS

The above and many other objects, features and attendant advantages of this invention will be appreciated more readily as the invention becomes better understood from a reading of the following detailed description, when considered in connection with the accompanying drawings, wherein like parts in each of the several figures are identified by the same reference characters, and wherein:

FIG. **1** is a diagrammatic, fragmentary, elevational view of a new blood transfer system using a novel alternating current electrically conductive treatment vessel in the form of conductive tubing to directly treat blood being transferred to a storage receptacle with electric field forces according to the invention;

FIG. **2** is an enlarged, horizontal cross sectional view of the novel electrically conductive tubing treatment vessel taken across lines **2—2** of FIG. **1**;

FIG. **3** is a longitudinal, vertical sectional view of the novel electrically conductive tubing treatment vessel taken along the staggered section lines **3—3** of FIG. **2**;

FIG. **4** is a view similar to FIG. **2** showing a different construction of the novel electrically conductive tubing treatment vessel;

FIG. **5** is a view similar to FIG. **3**, taken along the staggered section lines **5—5** of FIG. **4**;

FIG. **6** is a diagrammatic, fragmentary, elevational view showing a different modification of a novel blood transfer system using a novel electrically conductive tubing treatment vessel, and which employs a blood pump and a blood flow regulator;

FIG. **7** is an enlarged cross sectional view, similar to FIG. **2** that shows an electrically conductive tubing treatment vessel fabricated from longitudinally extending, integrally molded strips of alternate polarity, conductive polymer interconnected by integrally molded, insulating, longitudinally extending strips made of polymer or other insulating material;

FIG. **8** is a diagrammatic, fragmentary elevational view showing a different form of a blood transfer system according to the invention wherein a small electrically conductive vessel in the form of a short piece of tubing and a miniaturized battery power source are implanted in the arm of a human being to provide a novel electrically conductive blood and other body fluid treatment system which operates in a closed loop, recirculating manner;

FIG. **9** is a partial, diagrammatic sectional view of the upper arm portion of a human being and shows in greater detail the construction of a specially designed miniaturized, electrically conductive treatment vessel with associated miniaturized battery electric power source and DC to AC power converter for use in the implant treatment system shown in FIG. **8**;

FIG. **10** illustrates the details of construction of a somewhat different form of miniaturized electrified treatment tubing for use in an implanted treatment system of the type shown in FIG. **8** and built according to the invention;

FIGS. **11** and **11A** illustrate still a different construction for the electrified treatment tubing for use in practicing the invention wherein the tubing has a square or rectangular cross section with upper and lower conductive sides and intervening right and left sides separating the two conductive sides made from plastic or other suitable electrical insulating material;

FIG. **12** is a perspective top and side view of a novel electrified, closed, octagonally-shaped, flat, box-like treatment vessel having an enlarged cross sectional area relative to the cross sectional diameter of the inlet and outlet tubes supplying the interior of the treatment vessel;

FIG. **12A** is a partial, cross sectional view of the enlarged treatment vessel shown in FIG. **12**;

FIG. **13** is a perspective view of a second form of enlarged cross sectional area treatment vessel having an exterior shape similar to that of FIG. **12**, but wherein the electrically conductive electrodes of the treatment vessel comprise interleaved conductive plates with one set of alternate ones of the plates being electrically insulated from the remaining set, and wherein different polarity electric potentials are applied to the respective sets. If desired, the electrode plates may be formed from an electrically conductive porous material;

FIG. **13A** is a partial, cross sectional view taken through the electrically conductive treatment vessel shown in FIG. **13**;

FIG. **13B** is a sectional view taken through staggered line **13B**—**13B** of FIG. **13A**;

FIG. **14** is a longitudinal sectional view of still a different form of enlarged diameter electrified treatment vessel wherein the vessel is in the form of an elongated cylinder, and the sets of conductive electrodes mounted therein are concentrically arrayed within the interior of the treatment vessel and maintained at different electric potentials;

FIG. **14A** is a cross sectional view of FIG. **14** taken through plane A—A;

FIG. **15** is an enlarged longitudinal sectional view of still another form of an enlarged cross sectional area treatment vessel according to the invention wherein the electrically conductive electrodes of the treatment vessel are comprised by longitudinally extending needle-like electrodes with alternate ones of the needle-like electrodes being provided with opposite polarity electric potentials;

FIG. **15A** is a cross sectional view of the treatment vessel shown in FIG. **15** taken through plane A—A of FIG. **15**;

FIG. **16A** is a partial cross-sectional view taken through **16A**—**16A** of FIG. **16**;

FIG. **16** is a perspective view of still another form of enlarged cross sectional area treatment vessel according to the invention wherein the treatment vessel comprises a relatively large block of insulating material having parallel, longitudinally extending, open ended tubes formed through its length. The tubes are provided with electrically separated, opposed, parallel extending conductive plate electrodes which have opposite polarity electric potentials applied thereto. The ends of the tubes open into and are supplied from, or supply, respective reservoirs formed on the respective ends of the central block of insulating material containing the tubes, with inlet and outlet conduits for body fluids to be treated connected to the free ends of the respective reservoirs;

FIG. **17** is a perspective view of an enlarged cross sectional area treatment vessel similar to FIG. **16** wherein the body of the treatment vessel is cylindrical in nature;

FIG. **18** is a diagrammatic, fragmentary elevational view of a human blood or other body fluid treatment system according to the invention employing one of the larger cross sectional dimension fluid treatment vessels shown in any one of FIGS. **12–16** of the drawings, and which is suitable for use in a continuous flow through recirculating body fluid treatment system; and

FIG. **19** is a diagrammatic, fragmentary elevational view of still another human blood or other body fluid, closed loop, recirculating treatment system according to the invention designed for use with the enlarged diameter fluid treatment vessels illustrated in FIGS. **12–16**, and which employs both inlet and outlet fluid pumps on each side of the treatment vessel. With this arrangement the system can be operated in an intermittent manner to allow batch treatment of the body fluids to fully take place before passage of the body fluids being treated back to the patient.

BEST MODE OF PRACTICING INVENTION

FIG. **1** is a schematic illustration of one form of a novel blood and other body fluid treatment system according to the invention. FIG. **1** shows an electrically conductive blood and/or other body fluid treatment vessel constructed according to the invention which is in the form of intravenous tubing **11** interconnected between a hypodermic needle **12** and a blood storage receptacle **14**. The needle **12** is inserted in an artery or vein of the arm **13** of a blood donor and the tubing **11** leads from the arm **13** to the receptacle **14**. Alternatively, the system could be set up to transfer blood from the storage receptacle **14** to the arm of a recipient or could be designed to recirculate the blood through electrified tubing **11** back to the donor. The electrically conductive tubing **11** may be of any desired length as indicated by the break at **15** so that it can be appropriately set up to lead from a comfortable position for the donor from whose arm **13** the blood is being taken to a proper storage location for the receptacle **14**. The greater the length of the electrified portion of tubing **11**, then the more extended is the exposure of the blood (or other body fluid) to the electric field force effects and low level, biologically compatible current flow through the body fluid being treated thereby assuring adequate electrification treatment of the fluid without impairing the biological usefulness of the blood or other body fluid being treated.

FIG. **2** is a cross sectional view of the electrically conductive tubing **11** taken through plane 2—2 of FIG. **1**. The tubing **11** may be from 1 to about 20 millimeters in inside diameter, although it may be larger or smaller in diameter depending upon the intended application. For example, if the blood transfer system is for the purpose shown in FIG. **6**, then the tubing may have a cross sectional dimension of about 5 millimeters. However, if the intended use is in an implanted blood treatment system, such as shown in FIG. **8**, then the tubing diameter must be designed to result in a flow-through rate corresponding to the natural circulatory blood flow rate of the patient in which the system is implanted, and must be long enough to assure effective electrification treatment at the flow rate selected. The tubing **11** is formed from plastic, rubber, medical grade polymer, or other suitable material which is compatible with human fluids and/or tissue. A plurality of physically separated, electrically conductive surface segments form opposed, parallel electrodes shown at **16** and **16A** on the inside of tubing **11** from electrically conductive materials such as platinum, platinum alloys, silver, silver or platinum covered alloys, or other similar conductive materials such as conductive polymers, or silver or platinum covered polymers which are compatible with human fluids and tissue. The spacing between opposed electrodes **16** and **16A** is of the order of 1 to 19 millimeters and perhaps may be more or less dependent upon the application and the conductivity of the body fluids being treated.

FIG. **3** is a longitudinally extending sectional view along the axis of tubing **11** taken through staggered section lines 3—3 of FIG. **2**. From FIG. **3** of the drawings it will be seen that the electrically conductive surface segments **16** and **16A** all comprise longitudinally extending, zebra-like stripe or strip electrodes which extend longitudinally in parallel with the longitudinal axis of the tubing **11**. In between each longitudinally extending conductive stripe electrode **16** or **16A** is a longitudinally extending electric insulating area **17** which electrically isolates the alternate electrically conductive, zebra-like stripe electrodes **16** and **16A** one from the other.

As best shown in FIG. **3**, a first set of alternate electrically conductive surface stripes **16** are electrically connected in common to a first annular terminal buss **18** which circumferentially surrounds the tubing **11** and is embedded within the sidewalls of the tubing **11** at a suitable point along its length. The design is such that the first annular terminal buss **18** is electrically isolated from the remaining second set of alternate, electrically conductive surface stripe electrodes **16A** and is electrically connected through a conductor terminal **19** to an alternating current source of electric excitation potential. AC source **20** may comprise the output from an AC to AC voltage converter for converting 110 volt AC potential to the desired 0.2 volts to 12 volts for use in the invention. For those treatment systems which are to be implanted as described hereafter, the AC source may comprise a miniaturized DC to AC converter for converting the DC voltage from a miniaturized battery to low voltage (0.2 to 12 volts) AC. As best depicted in FIG. **2**, all of the first set of positive electrically conductive stripes **16** are physically and electrically connected in common to the first annular terminal buss **18** so that all of the conductive stripes **16** are maintained at a constant, alternating current electric excitation potential.

A second annular terminal buss **21**, which circumferentially surrounds the tubing **11**, is embedded within the tubing **11** at a point along its length displaced from the position of the first annular terminal buss **18** and is spaced inwardly towards the inside diameter of the tubing relative to the first annular buss **18**. By this arrangement it is possible to electrically connect the remaining second set of alternate electrically conductive surface stripes **16A** in common to the second annular terminal buss **21** in a manner such that the second annular terminal buss is electrically isolated from the first annular terminal buss **18** as well as the first set of alternate electrically conductive surface stripes **16**. As shown in FIG. **3**, the second annular terminal buss **21** is provided with an outside terminal conductor connection **22** for connecting the annular buss **21** and annular buss **18** across AC source **20** as shown in the system drawing of FIG. **1**. The second set of alternate electrically conductive surface stripes **16A** are all provided with internal connector studs which physically and electrically connect all of the **16A** stripes in common to the second annular terminal buss **21** so that all of these conductive stripes will be maintained at a potential opposite to that from the potential applied to the first set of electrically conductive stripes **16** by annular buss **18**.

As described earlier, the AC source of electric potential **20** may constitute an AC to AC converter for converting 110 volt AC to 0.2 to 12 volt AC or a DC to AC converter for converting 12 volt DC to 0.2 to 12 volt AC. The AC source **20** is connected to the conductor terminals **19** and **22** through electric supply conductors **23** and **24** preferably by a double pole, double throw, on-off control switch **25**. In preferred embodiments of the invention, voltage controlling variable resistors **26** and **27** also are included in the electric supply conductors **23** and **24** in order to control the value of the excitation voltage developed between the alternate sets of conductive surface stripes **16, 16A**.

In operation, the donor whose blood is to be taken, or the recipient who is to be given blood, or is to have his or her blood recycled, is made comfortable on a cot with his or her arm **13** extended and the interconnecting electrically conductive tubing **11** having the hypodermic needle **12** for withdrawal, or supplying, or recycling of blood set up as shown in FIG. **1**. When both the donor/recipient and the system is in readiness, the control switch **25** is closed so that an electric field is built up across the oppositely disposed electrically conductive zebra-like stripes **16, 16A**, etc. Voltages of the order of from 0.2 to 12 volts are applied to the conductive surfaces **16, 16A** For this purpose it is important to note that the hypodermic needle should be electrically isolated via conventional electrically insulating IV tubing from any of the zebra stripe electrodes **16, 16A** so that the donor/recipient does not receive a shock. By this precaution, he or she will not even be aware of the existence of the electric field within the electrically conductive tubing **11**. With the treatment system thus conditioned, the hypodermic needle is inserted into a vein in the donor's/recipient's arm and blood is withdrawn, given, or recycled through the tubing **11**.

As the blood passes through the electric fields produced within the electric conductive tubing **11** it will be subjected to and treated by biologically compatible electric current flow through the blood or other body fluid with a current density of from one microampere per square millimeter (1 $\mu A/mm^2$) of electrode cross sectional area exposed to the fluid to about two milliamperes per square millimeter (2 mA/mm^2) dependent upon field strength of the electric field gradient existing between electrodes **16** and **16A**, the space between the electrodes **16**, **16A** and the conductivity (resistivity) of the body fluid being treated. Recent experiments have proven that exposure to electric fields induced by supply voltages in the range produces electric current flow through blood of the order of 1 to 100 microamperes. Effectiveness is dependent upon length of time of treatment in conjunction with the magnitude of the biologically compatible current flow. For example, treatment of virus in media at 100 microamperes for 3 minutes has been observed to substantially attenuate (render ineffective) the AIDS virus. Similar treatment at other field strength values and lengths of time will have a similar attenuating effect on bacteria, virus, parasites and/or fungus which are present in blood or other body fluids being treated. By controlling the length of time and field strength values that blood is subjected to the electric field forces, undesirable contaminants such as virus, bacteria, fungus and/or parasites will be adequately attenuated to the point that they are rendered ineffective by the sustained action of the electric current flow as the blood travels from the hypodermic needle **12** to the storage bag **14**, or vice versa, or in a recycling mode. The length of travel of the blood through the sustained electric field induced current flow also can be adjusted so that the blood is subjected to the electric field force for time periods of the order of from one to six minutes at least. At the current values noted above this is believed adequate to attenuate (render ineffective) bacteria, virus (including the AIDS virus), parasites and/or fungus entrained in blood or other body fluids, but does not render the fluids unfit for human use or impair their biological usefulness.

The species of the invention shown in FIGS. **2** and **3** is advantageous since it is possible to fabricate the treatment tubing by preforming the conductive segments **16** and **16A** on the tubing walls while it is in a flat planar condition, and then rolling the walls into tubular form using a suitable mandrel. The adjoining longitudinal edges of the planar member after rolling are thereafter heat sealed along a longitudinally extending seam located within one of the electrically insulating sections **17**. Particular attention must be paid to the juncture of the ends of the annular terminal busses **18** and **21** during the rolling and heat sealing steps to assure that good electrical interconnection and continuity at these junctures of the annular terminal busses is provided in the completed treatment tubing. The conductive electrode segments **16**, **16A** may be electro-deposited, chemically formed, separately formed conductive polymer surfaces, or conductive foil or wires adhesively secured to the side walls of the tubing **11** in advance of the rolling and sealing using techniques well known in the printed circuit and integrated circuit manufacturing technologies.

FIG. **6** is a diagrammatic, fragmentary, elevational view of a modified blood treatment system using the novel electrically conductive treatment tubing in accordance with the invention. In the FIG. **6** embodiment of the invention, a blood pump **28** of conventional, commercially available construction is inserted in the tubing **11** at some point along its length. The blood pump **28** is electrically isolated from the zebra striped conductive surfaces **16**, **16A** by suitable insulators **29** formed on the blood input-output connections of pump **28**. Provision for electrically bypassing the blood pump **28** (if need be) is made through the shunt conductors **30**, **30A** which maintain electrical continuity of the alternating current excitation potential applied to the conductive stripes **16**, **16A** on each side of pump **28**. For convenience, the alternating current excitation source **20** and its connection to the electrically conductive tubing **11** has not been shown in FIG. **6** but would have to be provided. A separate source of excitation current for running the blood pump **28** is provided from a conventional 110 volt alternating current source through the input terminals **31**, **31A**.

In systems employing a blood pump, it may be desirable in some applications to provide a blood flow regulating valve **37** inserted in the system at the output of blood pump **28** and within the by-pass loop **30**, **30A** for the conductive stripes **16**, **16A**. By thus controlling blood flow, the electrified transfer system safely can be employed in a closed loop recycling system for withdrawing blood from a patient,. electrically treating the blood as described above and then returning the electrically treated blood to the patient. This procedure is referred to herein as recycling. The system of FIG. **6** also can be used in those situations where the blood flow of a donor's blood is not sufficient to assure supply of an adequate amount of blood to or from the collection receptacle **14** or other recipient. It may also be desirable to have a blood flow regulating valve such as **37** in non-pump systems.

FIGS. **4** and **5** of the drawings show another embodiment of the invention wherein the electrically conductive treatment tubing **11** includes electrically conductive electrode segments **32** and **32A** which are in the form of zebra stripes that extend radially around the inside diameter of tubing **11** in spaced-apart, alternating polarity, conductive annular bands **32** and **32A** separated by insulating surface bands **11I** which serve to electrically isolate the respective first set of conductive zebra stripes **32** from the second set of conductive zebra stripes **32A**. The first set of alternate ones of the electrically conductive annular stripes **32** are electrically connected in common to a first longitudinally extending terminal buss bar **33** that is embedded within tubing **11** in parallel with the longitudinal axis of the tubing and electrically isolated from the remaining second set of alternate electrically conductive annular stripes **32A**. The first longitudinally extending terminal buss bar **33** is designed for connection to one output terminal of a source, such as **20**, of alternating current electric excitation potential through a supply conductor connection **35** on the exterior surface of the tubing **11**.

A second longitudinally extending terminal buss bar **34** is embedded within the body of tubing **11** and is electrically connected to the remaining second set of alternate electrically conductive annular stripes **32A**. The second longitudinally extending terminal buss bar **34** is electrically isolated from the first longitudinally extending terminal buss **33** and the first set of altefnate electrically annular stripes **32**. Terminal buss bar **33** is designed for connection to a second output terminal for the alternating current source of electric excitation potential. For this purpose an input supply conductor connection **36** is directly connected through the exterior surface of tubing **11** and to the second longitudinally treatment extending terminal buss bar **34**.

In operation, the embodiment of the invention shown in FIGS. **4** and **5** is physically arranged in a blood treatment system in the manner illustrated in FIG. **1** of the drawings with the positive polarity and negative polarity zebra annular stripes being connected to the respective output terminals of AC source **20** via control switch **25**. If required, a blood pump such as **28** and blood flow regulating valve **37** shown in FIG. **6** can be included in the blood transfer system employing electrified tubing as shown in FIGS. **4** and **5**.

Similar to the system shown in FIG. **1**, a blood transfer system employing the embodiment of the invention shown in FIGS. **4** and **5** would be electrically excited in advance of injection of the hypodermic needle **12** into the arm of a blood donor so that all blood passing through the tubing **11** will be subjected to electric forces produced between the alternate polarity annularly formed conductive bands **32** and **32A**. Experience with the invention will establish what length is required for the electrification field. However, for initial installations the length of the electrified field as related to the flow of blood through electrified tubing **11** should correspond to at least the 1-6 minute treatment time mentioned earlier. This is achieved by using an extended array of the alternate annular zebra bands **32** and **32A** of adequate length to assure thorough subjection of blood to electric current flow produced between the alternating polarity zebra stripes **32** and **32A**. The electric field force intensity applied to the blood by means of the electrified tubing is anticipated to be of the order of from 0.2 to 12 volts similar to the embodiment of the invention shown in FIGS. **1-3**.

In place of supplying continuous alternating current excitation to the conductive stripes **16, 16A** of FIGS. **2** and **3** or **32, 32A** of FIGS. **4** and **5**, it also is possible to excite these electrically conductive segments of tubing **11** with pulsed waveform direct current excitation potentials. For use in this manner, the pulse rate of the pulsed waveform excitation potentials must be sufficiently high to maintain continuous current flow through blood being treated. In addition, it may be desirable to couple a bank of storage capacitors in parallel across respective pairs of opposite polarity electrically conductive segments **16, 16A** and **32, 32A** where operation in a pulsed DC mode is desired.

FIG. **7** of the drawings is a cross sectional view of another embodiment of the invention which is substantially different from those previously described. In FIG. **7**, the material used for fabrication of the tubing **11** is one of the new space-age polymer materials which can be either highly electrically conductive, insulating, or semiconducting and may have values of conductivity ranging from essentially fully conductive to insulating. In the embodiment of the invention of FIG. **7**, the conductive surface areas on the inside diameter of the tubing **11** are actually formed into segments, such as **11C**, of the cross sectional area of the tubing **11** fabricated from the highly conductive polymer material. The intervening segments of the tubing **11I** which separate the conductive segments **11C** are integrally formed from the highly insulating polymer material. Suitable positive polarity and negative polarity potentials are applied to the exterior surface areas of alternate ones of the sets of conductive polymer segments **11C** from a source of electric potential via the conductors **23** and **24** as illustrated schematically in FIG. **7**.

It will be appreciated that the embodiment of the invention shown in FIG. **7** is much simpler and hence less expensive to make in that it requires fewer processing steps than the embodiments of the invention shown in FIGS. **1-6**. In other respects, the embodiment of the invention shown in FIG. **7** would be used in a blood transfer system similar to that shown in FIG. **1** or **6** with or without a blood pump **28** and blood flow regulating valve **37** to effect transfer of blood from a donor to a receptacle or recipient in the event of a transfusion or recycling. During the blood transfer process, again it would be necessary to provide alternating current excitation potentials across the spaced-apart, alternate sets of electrically conductive polymer segments **11C** prior to passing blood through the tubing **11**. This will assure that all of the blood being transferred is subjected to the electric field forces produced between the alternate conductive surfaces **11C**. As a variation of the FIG. **7** embodiment, which visualizes that the segments **11C** and **11I** all extend longitudinally and parallel to the longitudinal axis of tubing **11**, it would be possible, but more elaborate to design, to employ alternate radially surrounding annular conductive segments **11C** and interlacing insulating segments **11I** similar to FIG. **5**, but such fabrication would require somewhat more complex terminal buss bar electric supply connections **23** and **24** than those shown in FIG. **7**.

FIG. **8** is a fragmentary, diagrammatic, elevational view showing a form of blood treatment system according to the invention wherein a small electrically conductive vessel **41** in the form of a short piece of electrified tubing and a combined miniaturized DC to AC converter and battery power source **42** are implanted in the arm of a human being. The electrified tubing **41** may be in the form of any of the prior disclosed electrified tubing structures described with relation to FIGS. **1-7**, but which are fabricated in miniaturized form so that the tubing **41** and power package **42** can be inserted in a section of or surrounding a vein **44** of the arm **13** of a patient whose blood is being treated. The implantation is such that the blood through the patient's vein **44** naturally is pumped through the short piece of electrified tubing **41** while circulating blood to the hand of the patient to thereby form a closed loop, recirculating, implanted treatment system that comprises an integral part of the circulatory system of the patient being treated. Because the parameters of such an implanted system are necessarily small, a single passage through the implanted electrified tube **14** may accomplish relatively little attenuation of contaminants in the blood. Therefore, it is the repeated passage of small portions of the patient's blood continuously twenty-four hours a day and for as many days as are needed which will gradually attenuate the contaminants to the point where they are rendered ineffective as described earlier.

FIG. **9** is a partial, fragmentary, sectional view of the upper arm portion **13** of a vein or artery of a patient in which a treatment system according to the invention has been implanted, and shows in greater detail the construction of a specialized, miniaturized, electrically conductive treatment vessel with associated miniaturized battery electric power source and DC to AC converter for use in an implanted treatment system as shown in FIG. **8**. In FIG. **9**, the electrified vessel **41** is in the form of an outer housing **45** that is in the shape of a football which is implanted within the interior walls **44** of an artery or a vein. The outer housing **45** is comprised by a central, cylindrically-shaped portion **45M** of solid conductor such as platinum which is biocompatible with human blood and tissue and has integrally formed, conically-shaped porous ends **45C** which are attached to and form an electrically conductive screen grid (at the same potential) as the mid portion **45M**. The conical end portions **45C** both are perforated and may be in the nature of a screen or mesh wire and of the same material composition as the mid portion **45M**. Disposed within the outer housing **45** is a inner housing **46** which is tear-drop shaped and secured within the central portion **45M** of the outer housing by suitable insulating support spider legs **47**. The inner housing **46** likewise is formed from platinum or other suitable biocompatible conductive material and has supported within its interior a miniaturized AC source comprising a miniaturized battery and AC to DC converter **42** secured to the conductive walls of inner housing **46** by conductive support legs **48**. The support legs **48** serve as terminal connectors from one terminal of AC power converter **42** to the inner housing **46** so that it is maintained at one polarity excitation potential. The remaining opposite polarity terminal of miniaturized AC source **42** is connected through an insulated conductor **49** to the central portion **45M** of outer housing **45** whereby the entire outer housing including the meshed conical end portions **45C** are maintained at an opposite polarity potential from the inner housing **46**.

Prior to implantation in a patient, the electrified vessel shown in FIG. **9** is activated by connection to AC source **42** so that an electric field gradient is produced across the space between the inner and outer housings **45** and **46**. Following implantation of the activated, electrified treatment vessel **41**, its presence in a vein or artery will cause all blood flowing through the vein or artery to pass between the side walls of the inner and outer housings **45** and **46** so as to be subjected to the electric field force gradient existing in these spaces. The presence of the electric field forces will induce a current flow through the blood passing between the interior and outer housings as explained above which will result in attenuating bacteria, virus, parasites and/or fungus which are present in the blood as contaminants. Here again, because of the relatively small portion of the total blood flowing in a patient that will be treated by the device within a given time period, it is the repeated, recycling process treatment of the blood over a prolonged period of time that will result in attenuation of the contaminants in the blood to the point where such contaminants are rendered ineffective as described earlier.

In order to further assure adequate treatment of the blood of a patient receiving the implant device, it is recommended that the blood be treated in an external treatment processing facility such as described earlier in FIGS. **1** and **6** or to be described hereinafter with relation to FIGS. **18** and **19** in which the total capacity of the treatment system is greater whereby substantial attenuation effect can be achieved in a comparatively shorter time period yet to be determined, and then the in vitro implant treatment system such as shown in FIGS. **8**, **9** and **10** can be used to maintain the attenuated condition and to prevent any subsequent build up of contaminants after the initial treatment, if determined to be desirable.

FIG. **10** is a fragmentary, diagrammatic view of a partial vein or artery **44** showing in greater detail the cylindrical or tubular electrified treatment vessel **41** originally described with relation to FIG. **8**. This implant treatment vessel **41** is miniaturized so that it is in effect an open-ended cylinder in shape and has a diameter comparable to that of a large vein or artery and so that it can be grafted or implanted into the vein or artery as illustrated in FIG. **10**. The tubular treatment vessel **41** may be designed pursuant to FIGS. **2** and **3** of the drawings, for example. For this application, the battery source of power and interconnected DC to AC converter **42** are annular in shape and are slipped over the tubular treatment vessel **41** in the manner shown. In FIG. **10** a longitudinal sectional view of the hollow annular-shaped treatment vessel **41** and AC power source **42** is illustrated. At the point where the battery driven AC power source **42** fits over the tubular treatment vessel **41**, the respective terminals of the AC power source **42** are exposed to engage the corresponding positive and negative supply terminals **19** and **22** of the tube **41** so that the resulting structure has a minimum exterior profile to facilitate implantation. From a comparison of FIG. **10** to FIG. **9** of the drawings, it will be appreciated that the FIG. **9** treatment vessel introduces some flow restriction in the vein or artery in which it is implanted and for this reason the construction shown in FIG. **10** is preferred.

FIGS. **11** and **11A** of the drawings illustrate a construction for the electrified treatment vessel **51** wherein the treatment vessel is in the form of square or rectangular cross sectionally-shaped open-ended tubing. The treatment tubing **51** provided with a square or rectangular shape so that provision of opposed, parallel conductive electrode surfaces **51U** and **51L** is greatly simplified as best seen in FIG. **11A** of the drawings, which is a cross sectional view taken through plane **11A—11A** of FIG. **11**. By fabricating the upper and lower surfaces of the tubing **11** from electrically conductive material such as platinum, etc., and separating the upper and lower surfaces **51U** and **51L** by electrically insulating side walls **52R** and **52L**, provision of the electrically isolated, opposed, parallel electrode surfaces is simplified and the resulting treatment vessel introduces minimum restriction to flow of blood. By connecting the upper surface **51U** to one terminal of the AC power source **42** and connecting the lower surface **51L** to the opposite terminal, AC electrification of the interior area of the tubing wherein the fluids to be treated flow is readily achieved with a greatly simplified electrode structure. Variations of this structural feature wherein the side insulating surfaces **52R** and **52L** are curved with their concave surfaces facing each other and the cross sectional area of the upper and lower conductive surfaces **51U** and **51L** tailored to provide a desired current density, tubular treatment vessels such as shown in FIGS. **11** and **11A** could be readily provided for use in implantation devices such as that illustrated in FIG. **8**.

FIG. **12** is a perspective view of a novel, electrified, closed, octagonally-shaped, flat, box-like treatment vessel **60** according to the invention which provides an enlarged cross-sectional area relative to the cross sectional diameter of the inlet and outlet tubing supplying the interior of the treatment vessel whereby increased through-put of a fluid being treated can be achieved in a given time period. The treatment vessel **60** shown in FIG. **12** is comprised essentially of upper and lower, octagonally-shaped, flat insulating plates **61** and **62**, respectively, of an insulating material which is compatible with human blood and/or other body fluids. Disposed immediately below and above the upper and lower plates **61** and **62** are octagonally-shaped, conductive electrode members **63** and **64**, respectively, which are separated and electrically isolated one from the other by a surrounding electric insulating gasket member **65**. The entire structure is sandwiched together and held in assembled relation by threaded thru-pins **66** as best seen in FIG. **12A** of the drawings. The insulating gasket **65** which may be of teflon defines an open space **67** between the two conductive electrode members **63** and **64** into which the blood or other body fluid to be treated is introduced via inlet and outlet conduits **68** and **69**. Alternating current electric potentials are applied across the respective conductive plates **63** and **64** to produce an electric field force across the intermediate space **67** through which the fluids being treated flow between electrode plates **63** and **64**. By thus structuring the treatment vessel, increased treatment surface area is provided to the blood or other body fluid flowing through the space **67** whereby in a given time period an increased quantity of fluids can be treated.

FIG. **13** is a perspective view of another form of enlarged cross sectional area treatment vessel **70** having an exterior shape similar to that of the treatment vessel shown in FIG. **12**. The electrified treatment vessel shown in FIG. **13** differs from that in FIG. **12**, however, in the construction of its electrically conductive electrodes which comprise a plurality of interleaved, conductive, flat, electrode plates **71** and **71A**. The electrode plates **71** are secured in and project inwardly from a right hand (RH) conductive end plate **73R** as shown in FIG. **13A**. The alternate set of flat electrode plates **71A** are secured to and project inwardly from a corresponding conductive end plate **73L** on the left hand end of the treatment vessel **70**. The conductive end plates **73R** and **73L** and coacting insulating side plates **72** which insulate the conducting end plates from one another, form an octagonally-shaped box frame which is closed by upper and lower insulating top and bottom insulating plates **74** and **75**. The conductive end plates **73R** and **73L** have a central opening formed therein into which inlet and outlet tubes **76** and **77** are secured as best seen in FIG. **13** for providing inlet and outlet flow through connection to the treatment vessel **70**.

The alternate sets of flat electrode plates **71** and **71A** extend parallel to one another and are provided with alternating current electric potentials supplied across the respective sets of interleaved electrode plates via the respective conductive end members **73R** and **73L**. If desired, the respective flat conductive electrode plates **71** and **71A** may be fabricated from a perforated material as shown in FIG. **13B** of the drawings. Also, it may be desirable that some form of thermal insulation, or a thermally controlled chamber be provided around the exterior of the treatment vessel **70** as indicated by the thermal insulation **78** shown in FIG. **13A**.

In operation, electrified treatment vessel **70** shown in FIGS. **13, 13A** and **13B** functions in essentially the same manner as was described earlier with respect to FIGS. **1-7** to effect attenuation of contaminants such as bacteria, virus and fungus contained in blood and/or other body fluids being treated in the flow through treatment vessel of FIG. **13**.

FIG. **14** is a longitudinal sectional view of still another form of enlarged cross sectional area, electrified treatment vessel **80**. The treatment vessel **80** shown in FIG. **14** is in the form of an open-ended, elongated cylinder **81** whose cylindrical walls are fabricated from an insulating material which is biocompatible with human blood and/or other body fluids and whose open ends are closed by circular-shaped conductive end pieces **82** and **83**. Inlet and outlet tubular openings **84** and **85** are provided to the interior of cylindrical housing **81** through centrally formed apertures in the circular end plates **82** and **83**. Within the interior of the cylindrical, insulating housing **81** at least two, separate, concentric, perforated, cylindrically-shaped electrode members **86** and **87** are provided which extend longitudinally through the interior of the outer cylindrical housing **81**. The first set of concentric, perforated, electrically conductive electrodes **86** is embedded in and supported by the conductive end plate **82** which serves as an electrical terminal for applying electric potentials to all of the concentric electrode member **86**. Similarly, the concentric, perforated, conductive electrode member **87** is physically supported by and electrically connected to the conductive end plate **83** for the supply of alternating current potentials thereacross. Additionally, if desired, one or more additional perforated concentric electrode members similar to **86** may be spaced apart from the inner concentric electrode member **86** outwardly along the diameter of the circular end member **82** with additional perforated concentric electrode members **87** being sandwiched between the two electrode members **86** and spaced apart therefrom so as to provide an electric field force between all the spaced apart, separated electrically conductive electrode members **86** and **87**. Additionally, if desired, a conductive surface **89** may be formed around the interior walls of the outer, insulating cylindrical housing member **81** and electrically connected to the conductive end plate **82** or **83**. This will assure that the entire interior of the treatment **80** vessel cross sectional area is crossed by the electric field force and all blood or other body fluid passing the cylindrical housing member **81** is subjected to biologically compatible low electric current flow as a consequence of the alternating current electric fields produced between the different concentric electrode members including the coated surface **89** within the interior insulating housing member **81**.

In operation, the embodiment of the invention shown in FIG. **14** and **14A** operates in substantially the same manner as described with relation to earlier embodiments of the invention to assure production of biologically compatible electric current flow through the blood or other body fluid being treated in the treatment vessel **80**.

FIG. **15** is a longitudinal sectional view of still another embodiment of an enlarged cross-sectional area treatment vessel **90**. The treatment vessel **90** again comprises an outer, hollow, open-ended cylindrically-shaped, insulating body member **91** whose open ends are closed by electrically conductive, circular end plates **92** and **93**, respectively. Inlet and outlet tubular openings **94** and **95** are provided through the central axial opening in the conductive end plates **92** and **93** for passage of blood and/or other body fluids being treated into the interior of the treatment vessel **90**. The conductive end plates **92** and **93** have respective sets of opposite polarity potential needle-like electrodes **96** and **97**, respectively, projecting therefrom inwardly into the interior of the treatment vessel **90**. Alternating current electric potentials are applied to the respective conductive end plates **92** and **93** through respective AC supply terminals indicated at **98** and **99**. If desired, and in order to assure complete saturation of the entire volumetric area within treatment vessel **90** with electric fields, a conductive coating similar to that shown at **89** in FIG. **14** can be provided to the inner surface of the hollow, cylindrically-shaped outer body member **91** of treatment vessel **90**.

FIG. **15A** is a cross sectional view taken through plane A–A of FIG. **15** and shows how the array of needle-like electrodes appear within the interior of the treatment vessel **90**. In operation, the treatment vessel **90** will function in substantially the same manner as has been described previously with relation to earlier described embodiments of the invention.

FIG. **16** is a perspective view of still another form of enlarged cross sectional area treatment vessel **100** according to the invention and FIG. **16A** is a partial cross sectional view taken through plane **16A—16A** of FIG. **16**. The treatment vessel **100** comprises a relatively large rectangular-shaped block **101** of electrical insulating material which is biocompatible with blood and/or other human body fluids. The insulating block **101** has a plurality of parallel, longitudinally extending, open-ended, tubular-shaped openings **102** formed therein through the entire length of the block. The tubes **102** are provided with electrically isolated, opposed, parallel extending conductive plate electrodes **109** as best shown in FIG. **16A**, which have alternating current electric potentials applied thereacross. One set of these electrodes, formed for example by the lower electrode **109** in each tube, extend out to and engage a conductive surface coating formed on one end of the insulating block, for example **101R**, and the remaining upper electrodes **109** form a second set which extend out of the left hand end of the tubes and contact a conductive coating formed on the remaining end **101L** of block **101**. Alternating current electric potentials are connected across the respective conductive surfaces **101R** and **101L** so that a potential difference exists between the sets of electrodes **109** within each longitudinally extending tube in block **101**. The ends of the tubes **102** open into and are supplied from, or supply, respective header reservoirs **103** and **104** formed on the respective opposite ends of the block of insulating material **101**. Each of the reservoirs **103** and **104** has a centrally formed opening for receiving either an inlet tube **105** applied to header **103** or an outlet tube **106** secured to header **104** for supply of blood or other body fluids to be treated to and from the treatment vessel **100**. If desired, a blood pump or other fluid pump can be inserted between the supply tube **105** and header **103**, or between outlet tube **106** and the or outlet from the header reservoir **104**, or both. Alternatively, both inlet and outlet pumps can be used. In operation, the electrified treatment vessel **100** shown in FIG. **16** functions in the same manner as those species of treatment vessels described previously.

For some treatment applications, it may be desirable to provide exhaust vents such as shown at **107** and **108** in FIG. **16** to the inlet reservoir **103** and/or the outlet reservoir **104** with the vents that can be selectively operated by valves that can be automatically or manually controlled for venting off gases that might be trapped in the tops of reservoirs and which otherwise might interfere with the proper operation of the electrified treatment vessel. In a similar manner, suitable venting apparatus may be provided to other of the large cross sectional area electrified treatment vessels described previously.

FIG. **17** is a perspective view of still another enlarged cross-sectional area treatment vessel **110** which is similar in all respects to the treatment vessel shown in FIG. **16** with the exception that the body or block of insulating material **101** through which the elongate tubular openings are made, is cylindrically shaped as illustrated in FIG. **17**. In other respects, the embodiment of the invention shown in FIG. **17** would be identical to FIG. **16** in the fabrication and operation of its component parts including the reservoir headers **103** and **104** and would operate in a similar manner.

FIG. **18** is a diagrammatic, sketch of a human blood or other body fluid treatment system employing one of the larger cross-sectional dimension fluid treatment vessels **60**, such as any one of those shown in FIGS. **12–17** of the drawings. The particular fluid treatment system shown in FIG. **18** is for a continuous flow-through recirculating body fluid treatment wherein blood is withdrawn from the arm **13** of a patient and supplied through IV tubing **111** to a commercially available blood pump **28** and thence to an electrified treatment vessel **60**. The treatment vessel **60** may be like any of the treatment vessels described with relation to FIGS. **12–17** of the drawings wherein the blood or other body fluid being treated is exposed to a low voltage, low current electric current flow for attenuating to the point of rendering them ineffective, any contaminants entrained in the blood, such as bacteria, virus and fungus. The treated blood appearing at the output of the treatment vessel **60** then is recirculated back through IV tubing **112** to the arm **13** of the patient whose blood or other body fluid is being treated. If desired, IV tubing **111** and **112** could also be treatment tubing such as described in FIGS. **1–7** and **11**. This could provide double treatment for the fluid if that were desirable. In the event that the entire treatment does not take place in an air conditioned, temperature controlled room, then it may be desirable to provide a temperature controlled enclosure indicated by dotted lines **78** around at least the pump **28**, electrified treatment vessel **60** and the interconnecting IV tubing sections **111** and **112** in order to assure maintaining a substantially constant viscosity of the blood or body fluid being treated.

Normally, the system of FIG. **18** would be used in a continuous flow-through recirculating treatment system wherein blood from the patient's arm **13** is supplied through pump **28** to the treatment vessel **60** where it is treated and then discharged back through tubing section **112** to the arm of the patient. The flow rate of the blood thus processed would be adjusted to correspond substantially to the natural flow rate of blood circulated through the patient's body to the extent possible.

In addition to operation in the above manner, it would also be possible to operate the system of FIG. **18** in a stopped-flow, batch treatment manner wherein the blood pump is intermittently stopped to allow for more extended electrical treatment of the blood or other body fluid contained in the treatment vessel **60** during the period of time (referred to as the dwell time) that the blood pump is stopped thereby assuring fuller electrification treatment and the greater attenuation of the bacteria, virus, parasites and/or fungus entrained in the blood.

FIG. **19** is a diagrammatic sketch of a form of closed loop, flow-through recirculating treatment system according to the invention that is somewhat similar to the system shown in FIG. **18**. FIG. **19** differs from FIG. **18** in that an inlet pump **28** and an outlet pump **28'** are connected to, respectively, the intake to and outlet from the electrified treatment vessel **60**. If desired, an inlet control valve **113** and an outlet control valve **114** also can be interconnected between the inlet pump **28** and the intake to the treatment vessel **60** and between the output from the treatment vessel **60** and the intake to the outlet blood pump **28'**. These inlet and outlet control valves indicated at **113** and **114** preferably are automatically operated in a time sequence which allows the system of FIG. **19** to be operated as a two pump, start-stop flow through system. When operated in this manner, the first pump **28** is allowed to operate and discharge blood from the arm **13** of the patient to be pumped into the treatment vessel **60** and thereafter is closed off with both the inlet and outlet valves **113** and **114** in their closed condition. At this point electrification treatment of the blood or other body fluid takes place for a predetermined, scheduled time period to assure adequate attenuation to the point of rendering ineffective the contaminant bacteria, virus, parasites or fungus. Upon completion of the pre-scheduled treatment period, the outlet valve **114** is opened and outlet pump **28'** actuated to return the treated blood to the arm of the patient **13**. Operation in this semi-continuous, start-stop, batch fashion will assure that adequate electrified treatment of the blood has been accomplished while achieving this end in a somewhat continuous manner suitable for use in a closed loop, recycling blood treatment process.

PRACTICAL USES OF INVENTION

While the disclosure herein presented has been directed to principally the electrical treatment of blood, it is believed obvious to those skilled in the art that the invention can be applied with corresponding effect to other body fluids which are electrically conductive for the treatment of contaminants such as bacteria, virus, parasites and/or fungus contained therein. Further, while voltages of the order of from about 0.2 volts to 12 volts AC have been indicated as preferable, it is possible that certain virus may be attenuated (or attenuated at a faster rate) if they are subjected to greater electric current magnitudes of the order of 500 microamperes for shorter time periods. Acceptable current magnitudes normally would require an excitation voltage of from 0.2 to 12 volts. However, in certain cases where faster or more complete attenuation of the contaminants in body fluids may be desired under certain circumstances and conditions, the excitation voltage supplied to the conductive tubing may in fact exceed the 0.2 to 12 volt range indicated for most treatments.

Although it is uncertain what is specifically causing the attenuation of the contaminants (virus, bacteria, parasites and/or fungus), some possible explanations have been put forward. One is that the attenuation is caused simply by the direct affect of the electric current and voltage. Another entails the following. When a voltage is applied to the electrodes, a small current will flow through the electrically conductive medium. The applied voltage and ensuing current will induce changes in the complex biologically active fluid. Current can flow through the media if positive and/or negative charges are transported through said media. The transport might induce changes in the charge distribution of the biologically active molecules thus changing their biological activity. Furthermore, the voltage and current can induce the production or elimination of different ions, radicals, gases and/or PH levels which may affect, alone or in combination, the biologically active molecules and/or cells. The above products of the electrical processes may either be very short lived and stay in the close proximity of the electrodes or can diffuse or mix in the bulk of the media and react with the biologically active molecules or cells to result in their attenuation.

Having described several embodiments of new and improved electrically conductive treatment methods and vessels for use in practicing the novel method for the treatment of blood and/or other body fluids with electric field forces and treatment systems employing the same, it is believed obvious that other modifications and variations of the invention will be suggested to those skilled in the art in the light of the above teachings. It is therefore to be understood that changes may be made in the particular embodiments of the invention described which are within the full intended scope of the invention as defined by the appended claims.

What is claimed is:

1. An electrically conductive vessel for direct electric treatment of bacteria, and/or virus, and/or parasites and/or fungus entrained in blood and/or other body fluids and/or synthetic fluids contained within or flowing through the vessel in the presence of electric field forces, said electrically conductive vessel being fabricated with only biologically compatible material contacting the fluid being treated and with an array of at least two or more spaced-apart, opposed electrically conductive electrode segments formed of biologically compatible conductive material on or in the interior surface of the vessel and exposed to blood or other fluids contained in or flowing through the vessel, said electrically conductive electrode segments being electrically isolated from each other and extending over or through a portion of the length of the vessel, and means for applying low voltage alternating current non-biologically damaging electric potentials to the electrically conductive electrode segments whereby electrical field forces are produced between the electrically conductive electrode segments that induce biologically compatible current flow through the blood and/or other fluids contained in or flowing through the vessel so as to attenuate bacteria, virus, parasites and/or fungus contained in the blood and/or other fluids by the action of the electric current flow therethrough to thereby render the bacteria, virus, parasites and/or fungus ineffective while not impairing and maintaining the biological usefulness of the fluids.

2. An electrically conductive vessel according to claim **1** wherein the low voltage alternating current electric potentials are in the range from about 0.2 volts to 12 volts and induce electric current flow densities in the blood or other fluids of from one microampere per square millimeter ($1\ \mu A/mm^2$) to about two milliamperes per square millimeter ($2\ mA/mm^2$).

3. An electrically conductive vessel according to claim **2** wherein the vessel is in the form of tubing and is inserted in a flow-thru blood treatment system between a hypodermic needle employed to withdraw and/or supply blood from a donor and/or to a recipient and/or a blood storage receptacle or to a patient in a blood recycling system.

4. An electrically conductive vessel according to claim **2** wherein the vessel is part of a system and is in the form of tubing and a blood pump is inserted in the tubing between a donor and a recipient or a receptacle, and the system further includes means for electrically isolating the blood pump from the electrically conductive vessel, means for regulating blood flow rate from the blood pump output and means for maintaining electrical continuity throughout a desired length of the conductive vessel.

5. An electrically conductive vessel according to claim **2** wherein the vessel is in the form of tubing and the electrically conductive electrode segments are in the form zebra stripes which extend longitudinally parallel with the longitudinal axis of the tubing with the alternate electrically conductive electrode stripes being separated by alternate electrically insulating stripes for electrically isolating the alternate electrically conductive electrode stripes one from the other, a first set of alternate ones of the electrically conductive electrode stripes being electrically connected in common to a first annular terminal buss formed on and circumferentially surrounding the tubing and electrically isolated from the remaining second set of alternate electrically conductive electrode stripes, said first annular terminal buss being designed for connection to one supply terminal of a source of alternating current electric excitation potential, and a second annular terminal buss circumferentially surrounding the tubing and electrically connected to the remaining second set of alternate electrically conductive electrode stripes, said second annular terminal buss being electrically isolated from the first annular terminal buss and the first set of alternate electrically conductive electrode stripes and being designed for connection to a second supply terminal of a source of alternating current electric excitation potential.

6. Electrically conductive tubing according to claim **5** wherein the tubing is inserted in a flow-thru blood treatment system between a hypodermic needle employed to withdraw and/or supply blood from a donor and/or to a recipient and/or a blood storage receptacle or to a patient in a blood recycling system.

7. Electrically conductive tubing according to claim **5** wherein a blood pump is inserted in the tubing between a donor and a recipient and/or a receptacle, and the tubing is a part of a system which further includes means for electrically isolating the blood pump from the electrically conductive tubing, means for regulating blood flow rate from the blood pump output, and means for electrically interconnecting the input and output sides of the tubing around the blood pump and the blood flow regulating means whereby electrical continuity is maintained throughout a desired length of the tubing.

8. An electrically conductive tubing according to claim **2** wherein the vessel is in the form of tubing and the electrically conductive electrode segments are in the form of zebra stripes which extend radially around the inside diameter of the tubing in alternating conductive and insulating annular bands whereby alternate conductive bands are electrically isolated one from the other by respective insulating bands, a first set of alternate ones of the electrically conductive annular electrode stripes being electrically connected in common to a first longitudinally extending terminal buss that is formed on the tubing in parallel with the longitudinal axis thereof and electrically isolated from the remaining second set of alternate electrically conductive annular electrode stripes, said first longitudinally ext ending terminal buss being designed for connection to a first supply terminal of a source of alternating current electric excitation potential, and a second longitudinally extending terminal buss electrically connected to the remaining second set of alternate electrically conductive annular electrode stripes, said second longitudinally extending terminal buss being electrically isolated from the first longitudinally extending terminal buss and the first set of alternate electrically conductive annular electrode stripes and being designed for connection to a second supply terminal of a source of alternating current electric excitation potential.

9. Electrically conductive tubing according to claim **8** wherein the tubing is inserted in a flow-thru blood treatment system between a hypodermic needle employed to withdraw and/or supply blood from a donor and/or to a recipient and/or a blood storage receptacle or to a patient in a blood recycling system.

10. Electrically conductive tubing according to claim **9** wherein a blood pump is inserted in the tubing between a donor and a recipient and/or a receptacle, and the tubing is part of a system that further includes means for electrically isolating the blood pump from the electrically conductive tubing, means for regulating blood flow from the output of the blood pump, and means for electrically interconnecting the input and output sides of the tubing around the blood pump and blood flow regulating means whereby electrical continuity is maintained through a desired length of the tubing.

11. An electrically conductive vessel according to claim **2** wherein the walls of the vessel itself are formed from electrically conductive polymer material that is compatible with human tissue and blood and/or other body fluids with the electrically conductive portions being formed into desired patterns of spaced apart electrically conductive electrode segments physically interconnected by integrally formed electrically insulating tubing walls portions which electrically isolate a first array of electrode segments from a second array of electrode segments.

12. An electrically conductive vessel according to claim **11** wherein the vessel is in the form of tubing and the electrically conductive electrode segments are in the form of zebra stripes which extend longitudinally parallel with the longitudinal axis of the tubing with the alternate electrically conductive electrode stripes being separated by alternate electrically insulating stripes for electrically isolating the alternate electrically conductive electrode stripes one from the other, a first set of alternate ones of the electrically conductive electrode stripes being electrically connected in common to a first annular terminal buss formed on and circumferentially surrounding the tubing and electrically isolated from the remaining second set of alternate electrically conductive electrode stripes, said first annular terminal buss being designed for connection to one supply terminal of a source of alternating current electric excitation potential, and a second annular terminal buss circumferentially surrounding the tubing and electrically connected to the remaining second set of alternate electrically conductive electrode stripes, said second annular terminal buss being electrically isolated from the first annular terminal buss and the first set of alternate electrically conductive electrode stripes and being designed for connection to a second supply terminal of a source of alternating current electric excitation potential.

13. Electrically conductive tubing according to claim **12** wherein the tubing is inserted in a flow-thru blood treatment system between a hypodermic needle employed to withdraw and/or supply blood from a donor and/or to a recipient and/or a blood storage receptacle or to a patient in a blood recycling system.

14. Electrically conductive tubing according to claim **13** wherein a blood pump is inserted in the tubing between a donor and a recipient and/or a receptacle, and the tubing is part of a system which further includes means for electrically isolating the blood pump from the electrically conductive tubing, means for regulating blood flow from the output of the blood pump, and means for electrically interconnecting the input and output sides of the tubing around the blood pump and blood flow regulating means whereby electrical continuity is maintained throughout a desired length of the tubing.

15. An electrically conductive vessel according to claim **11** wherein the vessel is in the form of tubing and the electrically conductive electrode segments are in the form of zebra stripes which extend radially around the inside diameter of the tubing in alternating conductive and insulating annular bands whereby alternate conductive bands are electrically isolated one from the other by respective insulating bands, a first set of alternate ones of the electrically conductive annular electrode stripes being electrically connected in common to a first longitudinally extending terminal buss that is formed on the tubing in parallel with the longitudinal axis thereof and electrically isolated from the remaining second set of alternate electrically conductive annular electrode stripes, said first longitudinally extending terminal buss being designed for connection to a first supply terminal of a source of alternating current electric excitation potential, and a second longitudinally extending terminal buss electrically connected to the remaining second set of alternate electrically conductive annular electrode stripes, said second longitudinally extending terminal buss being electrically isolated from the first longitudinally extending terminal buss and the first set of alternate electrically conductive annular electrode stripes and being designed for connection to a second supply terminal of a source of alternating current electric excitation potential.

16. Electrically conductive tubing according to claim **15** wherein the tubing is inserted in a flow-thru blood treatment system between a hypodermic needle employed to withdraw and/or supply blood from a donor and/or to a recipient and/or a blood storage receptacle or a patient in a blood recycling system.

17. Electrically conductive tubing according to claim **16** wherein a blood pump is inserted in the tubing between a donor and a recipient and/or a receptacle, and the tubing is part of a system that further includes means for electrically isolating the blood pump from the electrically conductive tubing, means for regulating blood flow from the output of the blood pump, and means for electrically interconnecting the input and output sides of the tubing around the blood pump and the blood flow regulating means whereby electrical continuity is maintained throughout a desired length of the tubing.

18. A fluid treatment process for attentuating bacteria, and/or virus, and/or parasites, and/or fungus, existing in blood and/or other body fluids and/or synthetic fluids within a treatment vessel having only biologically compatible internal and conductive electrode surfaces therein contacting fluid being treated thereby maintaining the biological usefulness of the blood or other fluids being treated comprising subjecting the fluid within the treatment vessel to low voltage, low alternating current electric field forces within non-biologically damaging electric field forces for producing a biologically compatible current flow through the blood or other fluids for a predetermined period of time sufficient to attenuate bacteria and/or virus, and/or parasites and/or fungus contained in the blood or other fluids to thereby render them ineffective while maintaining the biological usefulness of the fluids being treated.

19. The product of the process according to claim **18**.

20. A fluid treatment process according to claim **18** wherein the low voltage alternating current electric potentials are in the range from about 0.2 to 12 volts and induce electric current flow densities in the blood or other fluids of from one microampere per square millimeter (1 $\mu A/mm^2$) to about two milliamperes per square millimeter (2 mA/mm^2).

21. The product of the process according to claim **20**.

22. A fluid treatment system for attentuating bacteria, and/or virus, and/or parasites, and/or fungus existing in blood and/or other body fluids and/or synthetic fluids being treated without biological damage to the blood or other fluids comprising an electrically conductive vessel formed at least in part of biologically compatible conductive material for contacting blood or other fluids to be treated, means for subjecting the blood or other fluids within the conductive vessel to low voltage, low alternating current electric field forces for producing biologically compatible current flow through the blood or other fluids for a predetermined period of time sufficient to attenuate bacteria and/or virus, and/or parasites, and/or fungus contained in the blood or other fluids to thereby render such contaminants ineffective while maintaining the biological usefulness of the blood or other fluids.

23. A fluid treatment system according to claim **22** wherein the low voltage alternating current electric potentials are in the range from about 0.2 to 12 volts and produce electric current flow densities in the blood or other body fluids of from one microampere per square millimeter (1 $\mu A/mm^2$) to about two milliamperes per square millimeter (2 A/mm^2).

24. A fluid treatment system according to claim **22** wherein the system comprises a plurality of components including an electric power source all of which the miniaturized and implanted in the body of a patient being treated to form a closed loop, continuous recirculating body fluid treatment system.

25. A fluid treatment system according to claim **22** wherein the conductive vessel is in the form of an open ended tube to allow flow-thru treatment of blood and other fluids and is miniaturized along with an electric power source for supply of alternating current electric potentials thereto whereby the system may be implanted in human beings and other mammals to operate as a continuous recirculating fluid treatment process.

26. A fluid treatment system according to claim **22** wherein the conductive vessel in the vicinity of the spaced-apart opposed electrically conductive electrode segments is provided with an enlarged cross sectional area wherein enlarged electrically conductive electrode segment surface areas are provided to act on the blood or other fluids flowing through the vessel thereby increasing the through-put and/or effectiveness of the treatment accomplished within the vessel for a given dwell time.

27. A body fluid treatment system according to claim **26** wherein the electrically conductive vessel comprises an enlarged rectangular-shaped body of electrical insulating material having a plurality of parallel, longitudinally extending tubular openings formed all the way through the insulating material from one end to the other and having spaced-apart electrically conductive metal strips secured to respective opposite sides of all of the tubes in opposed, parallel relationship, one set of corresponding conductive strips of all of the tubes extending out of the ends of each tube on one side or end of the body of electrical insulating material and contacting a conductive surface forming a terminal buss for all conductive strips of the set, and the remaining set of conductive strips projecting out of the opposite ends of the respective tubes on the opposite end of the insulating block to engage a conductive terminal surface, and header reservoirs formed on each of the ends of the body of electrical insulating material into which the ends of the tubular openings are connected, each header having a respective inlet or outlet opening for supply of blood and/or other fluids for treatment thereto.

28. A fluid treatment system according to claim **27** wherein the enlarged insulating clock member is cylindrically shaped and the header reservoirs at each end of the block member are correspondingly cylindrically shaped.

29. A fluid treatment system according to claim **27** wherein selectively operated gas vents are provided in the top of the respective header reservoirs of the electrically conductive vessel.

30. A fluid treatment system according to claim **26** wherein the electrically conductive vessel is in the form of an enlarged cross sectional area treatment vessel of substantially greater cross sectional area than the inlet and outlet conduits supplying body fluids to be treated to the vessel and wherein the enlarged cross sectional area vessel is included in a blood transfer system between a hypodermic needle employed to withdraw and/or supply blood from a donor and/or to a recipient and/or a blood storage receptacle or to a patient in a continuous flow-thru blood recycling system.

31. A fluid treatment system according to claim **30** wherein a blood pump is inserted in the flow path of the blood or other fluid either to or from the enlarged cross sectional area vessel, or both, and are located in a tubing system between the donor and recipient or receptacle, and the system further includes means for regulating blood flow rate from or to the enlarged cross sectional area treatment vessel via the inlet or outlet pumps or both.

A Cheap, Portable Wound-Healing Device

After the Haiti earthquake, physicians tested a vacuum pump meant to speed healing.

by

Emily Singer

In mid-February, about a month after a massive earthquake leveled much of Port-au-Prince, Haiti, a wound-care team from Brigham and Women's hospital in Boston traveled to the devastated capital. The team's task was to help care for scores of patients suffering from the large open wounds that accompany amputations, crushed limbs, and other injuries. Among the team was MIT graduate student Danielle Zurovcik, who arrived ready to test a device she had developed as part of her thesis research–a cheap and portable version of the negative-pressure devices currently used to speed wound healing in hospitals.

Zurovcik and her collaborators hope the device, which costs about $3, will provide a way to improve care for patients after the emergency phase of relief efforts, including life- and limb-saving surgeries, has ended. Even after many of the emergency medical teams leave the disaster zone, the dangers of chronic wounds remain high.

“My experience in Haiti and other major earthquakes is that after the acute medical response, such as amputating limbs and setting fractures, the major disease burden is wounds,” says Robert Riviello, a trauma surgeon at Brigham and Women’s, and Zurovcik’s collaborator. Negative-pressure therapy decreases the need to change wound dressings from one to three times per day to once every few days, a major benefit when medical staff is in short supply.

Negative-pressure devices, which act like a vacuum over the bandaged wound, have become a central part of wound therapy in the United States over the last decade. They speed healing up to threefold, depending on the type of wound, and in some cases eliminate the need for plastic surgery or skin grafts. A number of commercial versions are available in the U.S. and are used to treat burns and chronic wounds such as bed sores or diabetic foot ulcers. While scientists don’t exactly know why this treatment accelerates the healing process, it likely helps by removing some of the fluid and bacteria that accumulates at the injury site and by increasing blood flow to the wound. The pressure itself may also help healing by bringing together the edges of the wound and delivering mechanical pressure, which has been shown to spur cell growth, says Dennis Orgill, a surgeon at Brigham and Women’s who was not involved in the project.

Existing devices are often heavy, about five to 10 pounds, and require an energy source to create the vacuum, making them difficult to apply in disaster settings. Texas-based KCI, the leading maker of negative-pressure machines, has a portable version that’s battery powered, but it costs approximately $100 per day to rent. A number of companies are working on even more portable versions, say Orgill.

But Zurovcik, inspired by a burn surgeon’s plea, went a step further, designing a human-powered device that applies pressure via a simple bellows pump weighing less than half a pound. By improving the seal around the wound dressing to reduce air leaks, Zurovcik cut the pump’s power requirements from about 14 watts to 80 microwatts, which comes from a hand pump.

“To basically take a toilet plunger and produce negative pressure over a prolonged period of time, that is really great,” says Kristian Olson, a physician at Massachusetts General Hospital, in Boston, who was not involved in the project. “Not only do I see it answering this need in developing countries, I think it could really enhance home therapy for chronic wounds in the U.S.”

Zurovcik and Riviello had been planning a trial of the device in Rwanda – Riviello spends about half his time working in Africa–when the earthquake hit Haiti. Colleagues treating the first waves of injury victims told the duo that their device might be of help, so they joined a wound-care team headed for University Hospital, a few blocks from the leveled palace in Port-au-Prince. (Commercial negative-pressure devices, known as VACS, were employed in various relief efforts in Haiti, including $2 million worth of equipment donated by KCI.)

Working in stifling tents filled with patients, the team tended to those whose doctors had left and were in need of follow-up care. Of the hundreds of patients assessed, the researchers chose eight people suffering from a variety of injuries– amputations, open tissue wounds, open fractures, crushing injuries (where the skin had to be opened to give the muscle room to expand), infected surgical wounds, and bedsores from being paralyzed–appropriate for negative-pressure therapy. “Because this was a disaster setting, we didn’t feel it was an appropriate place for rolling out a randomized controlled trial,” says Riviello. (They cared for other patients with typical dressings.)

The surgeon would first apply a sponge over the cleaned wound and then cover it with a plastic seal. A tube fed through a small hole in the plastic connected to the pump, which was manually compressed to create negative pressure. The team trained patients’ families, who often took on typical nursing duties, to charge, or pump, the device. “We learned that family members are interested in being trained and motivated to keep the device charged because they saw the benefits for their loved ones," says Riviello. "They were tremendously reliable. We saw patients twice a day, but it became clear that we could come back days later and the device would still be charged."

Because the researchers were in Haiti for just 10 days, they weren't able to determine if the device helped patients heal faster. But it did seem to keep the wounds cleaner, says Riviello, and reduced the need to change bandages, which is painful for the patient. In fact, one patient requested the treatment after observing how a neighbor in the next bed was subjected to fewer painful dressing changes, says Zurovcik. Now back in Cambridge, she is tinkering with the prototype, trying to further improve the pressure seal and the amount of negative pressure the device can deliver.

The team plans a larger test in Rwanda, where it will likely put the device to broader use. People in poor countries are much less likely to survive severe burns, for example, which can be helped with negative-pressure therapy. And the rate of complications from diabetes, such as foot ulcers, is skyrocketing in these countries as well, says Olson.

Modifiable Occlusive Skin Dressing
US2014031735

[PDF]

Occlusive tissue dressings and methods including an elastomeric drape and a liquid component, at least partially cross-linked at least after one of drying and curing, suitable for application at a dressing-to-skin interface in order to create a substantially air-tight seal. The same or a different liquid component may be applied by a user at a tube-to-dressing interface in order to create a similar air-tight seal around the tube, if not occlusively sealed during its manufacture.

CROSS-REFERENCE TO RELATED APPLICATION

[001] This application claims priority to U.S. Patent Application No. 13/745,690 filed January 18, 2013 and U.S. Provisional Application No. 61/588,121 filed 18 January 2012.

FIELD OF THE INVENTION

[002] This invention relates to dressings intended to provide a fluid-impervious barrier over skin, and more particularly to dressings suitable for negative pressure wound therapy.

BACKGROUND OF THE INVENTION

[003] Negative pressure wound therapy ("NPWT") is an effective technology for treating open wounds. NPWT devices were originally accepted by the US Food and Drug Administration ("FDA") in 1995, when the FDA approved a 510(K) for the Kinetic Concepts Inc. ("KCI")'s V.A.C.(R) device. The definition of NPWT devices by the FDA has changed over the years; in general terms, its definition is: a system that is used to apply negative pressure for wound management purposes, including the removal of fluids (i.e., wound exudates, irrigation fluids, and infectious materials). The negative pressure is applied through a porous dressing positioned into or over the wound cavity, depending on wound type and depth, or over a flap or graft; the dressing distributes the pressure while removing fluids from the wound. NWPT systems typically include:

<-> Non-adhesive wound dressing used to fill the wound cavity (e.g., a sterilized medical sponge or gauze; a.k.a., non-adhesive packing materials);

<-> Drainage tube placed adjacent to or into the dressing;

<-> Occlusive transparent film placed over the dressing (and potentially the drainage tube) and adhered to

the skin to maintain a seal;

<-> Collection container for drained fluids from the wound; and

<-> Low pressure vacuum source.

[004] NPWT has been approved by the FDA to treat many wound types: chronic, acute, traumatic, sub-acute and dehisced wounds, partial-thickness burns, ulcers (such as diabetic, venous or pressure), surgically closed incisions (a.k.a., closed surgical incisions), flaps and grafts. The prescribed therapy time depends on wound type, wound dimensions, and patient conditions; it typically lasts from four weeks to four months. Disposable dressing components are changed approximately every three days.

[005] Extensive clinical trials have demonstrated the success of negative pressure in healing the approved wound types by applying a controlled negative pressure typically between 20mmHg and 200mmHg. Most studies applied a constant vacuum pressure, with 125mmHg being the most common, although cyclic and intermittent studies are currently underway. Evidence supporting the use of NPWT in the treatment of chronic, non-healing wounds exists primarily in the form of nonrandomized, controlled trials; prospective and retrospective large and small case series; single-center studies; and single case studies, with few randomized, controlled clinical trials. Studies also exist that demonstrate NPWT benefits in healing acute wounds. Additionally, since 2006, benefits of managing surgical incisions post-operatively have been shown with improved clinical outcomes; at least ten studies have been published to date. From these studies, proven medical benefits of NPWT treatment include:

<-> Promotes blood flow (perfusion) at the wound;

<-> Removes interstitial fluid (a.k.a., wound exudates), reduces edema;

<-> Decreases counts of bacteria and infectious materials;

<-> Increases rate of granulation tissue formation, reducing scar tissue formation, increases growth factors and fibroblasts;

<-> Uniformly draws the wound edges together;

<-> Provides a protected healing environment; and

<-> Provides a moist environment.

[006] Although significant clinical evidence exists to support the benefit of NPWT as a safe therapy in healing chronic wounds, it is possible during NPWT to rupture a vein or artery. Usually, a machine safety alarm will signify a fluid leak rate that exceeds the rate that the machine was designed for. This alarmed leak rate typically includes the combination of both air and liquid, and typically has an upper safety limit of the minimum blood flow rate possible out of a wound cavity with an actively bleeding vein or artery. If a vein or artery accidently ruptures, the system must shut down. Therefore, it is very important to have a safety feature that stops blood flow if this occurs, in order not to exsanguinate the patient.

[007] Lina et al. describe in U.S. Patent No. 7,611,500 and WO1996/005873 an initial apparatus used for NPWT. In practice, the device proved to be effective; however, one major limitation was detected: the high electrical grid power source needed to operate the device limited the mobility of a patient. Therefore, future refinements, such as that described by Hunt et al. in U.S. Patent No. 6,142,982, incorporated rechargeable batteries for the power source. Batteries increased patient mobility, but time was limited by the life of the batteries between charges. Additionally, battery management became an issue, especially for facilities with a high number of NPWT patients, and electrical grid power was still needed to recharge the batteries.

[008] Eliminating the need for electrical power, via the grid or batteries, would create a more widely applicable, clinically viable therapy. The power requirement variability of a system is dependent on the desired vacuum pressure, rate of wound exudate removal from the wound cavity, and the leak rate of air into the system. As the air leak rate increases, more power is needed to supply a continuous negative pressure at

a predetermined value or threshold range at the wound bed. Air leakage into the NPWT system requires the most power of any other component. Air leaks are the obstacle to creating a vacuum system that does not require a continuous external power source or frequent recharging of its internal power storage. Therefore, the feasibility of a mechanical NPWT system is heavily reliant on the seal quality of every interface in the system. The dressing system has been identified as the main source of air leaks in current NPWT systems, particularly at the interfaces between 1) the dressing and the skin and 2) the tube and the dressing. The amount of air leaks into these interfaces determines the time frequency that the pump needs to be recharged and the magnitude of vacuum pressure applied to the wound cavity at a specific time. These two latter characteristics are dependent system parameters.

[009] Few mechanical NPWT systems are currently available, as described by the present inventor in "Development of a simplified Negative Pressure Wound Device" submitted in 2007 for her Master of Science in Mechanical Engineering at the Massachusetts Institute of Technology. Certain lower-pressure, mechanical devices were disclosed later by Hu et al. in U.S. Patent Application No. 2010/0228205. Current mechanical systems typically use sophisticated-material, planar dressings, such as hydrocolloid dressings, to try to solve the air leak problem. However, the inherent geometry mismatch of a planar dressing and the contoured skin surface often leads to air leaks. The mechanical devices therefore are only applicable for select, relatively flat surfaces on the body and, even then, it is difficult to eliminate air leaks entirely. [010] Non-electrical pumps are at the low end of the spectrum of medical pumps, typically utilizing bladder pumps and capillary action materials. Bladder pumps are used for both extracting and inserting fluids. By their physical characteristics, they are governed by non-linear spring like properties. Currently, bladder pumps are used in wound treatments for drainage purposes, particularly for internal, body cavity drainage. C. R. Bard, Inc. manufacturers many of these non-electrical pumps; one bladder model frequently used to drain internal cavities is commonly referred to as a Jackson Pratt Drain.

[011] There are various limitations to applying NPWT with existing mechanical, bladder pumps. There are no pressure gauges on the pumps and, therefore, the user does not know the initial magnitude of the negative pressure pulled, and cannot monitor the pressure during therapy. Additionally, there are no air leak detection systems for the current pumps, except to visually watch for the expansion of the bladder at a rate higher than expected. If the pump is clear, one can also visually monitor if the expansion rate is due to air leaks or due to drainage fluid.

[012] Capillary action materials are also currently used to treat wounds by providing very low negative pressure treatment, too low to be considered NPWT. This form of treatment is usually found in dressings such as small topical bandages to provide NPWT- like benefits to very small, self-healing wounds, such as blisters and brush burns. Treating a wound with this technology enhances the healing environment. Capillary action materials are filled with small capillaries between the wound and outside environment. A negative pressure is applied by capillary action of fluid flowing from the wound to the outside environment, thereby, removing interstitial fluid. One example of a capillary action material is Johnson & Johnson's First Aid Advanced Care Advanced Healing Adhesive Pads.

[013] Dressing technologies have tried to address the issue of air leaks into NPWT systems. This is important to both electrical and mechanical systems to reduce their necessary power requirements. In mechanical systems, it is necessary for clinically relevant device functionality, such that power input and pump recharge time is reasonable for a caregiver and/or patient to perform. For electrical systems, air leak reduction reduces the number of, if not completely eliminates, false-positive, alarmed emergency system shutdowns. Air leak reduction allows battery designs to last longer on one battery charge and use lower power capacity batteries altogether. Air leak elimination potentially eliminates the need for a continuous power supply, as the vacuum pressure can be maintained in the occlusive environment within a specified threshold, for which the timeframe depends on the pump parameters and exudate removal rate (typically less than 100 mL/day) from the wound.

[014] Currently, most NPWT dressings (the drape component) are thin, planar, tape-like adhesive dressings that must be applied to a contoured area of skin. A backing on the dressing must be removed to expose the adhesive, and then the dressing is applied to the skin. The pre-application handling of the dressings alone introduces a probability for air leaks, as the dressing typically folds onto itself or creases very easily due to its low bending stiffness; many dressings are thinner than a piece of standard paper, and the bending stiffness of a material is proportional to the inverse of its thickness cubed. As a dressing is applied, it must

often fold onto itself in order to accommodate for a geometrical mismatch between the planar dressing and the contours of the body surrounding the wound to be treated. This creates creases, also referred to herein as wrinkles, in the dressing that have a high potential for causing air leaks into the NPWT system.

[015] Adding to the geometrical mismatch, the dressings often become less adhesive due to the introduction of foreign materials onto the adhesive before dressing application. This is most common and almost unavoidable at the edges of the dressing due to handling by the caregiver. At times, the caregiver's hands introduce enough foreign particles onto the adhesive to forbid further adhesion of that area of the dressing. In the U.S., this often happens when a caregiver uses powdered gloves. This is a critical issue as the edges of the dressing are an area where leak propagation from the edge of the dressing to the wound cavity is potentially very high, based on the theory of interface fracture mechanics.

[016] For the electrical NPWT systems, a thin plastic, adhesive backed dressing is typically used. Electrical NPWT dressing systems have not readily addressed the air leak issues listed above that form at the dressing-to-skin interface. Instead, dressing iterations have focused on air leaks at the tube-to-dressing interface. When NPWT was first introduced into the market, the drainage tube was inserted into the wound cavity through the edge of the dressing. This introduced a high potential for air leaks, which often alarmed the shut-off system. Caregivers began to solve this problem by raising the tube from the skin surface at the dressing edge, and pinching the dressing under the tube before the dressing contacts the skin. This caused the dressing to adhere to itself in an upside-down "T" pattern onto the skin. [017] Eventually, some of the NPWT dressing, commercial designs incorporated their own solutions to the high air leak rate at the tubing interface. Out of these solutions, the T.R.A.C. Pad by KCI was highly effective, which is driving the current design trends. The T.R.A.C. Pad prefabricates the drainage tube to a semi-rigid, tubing connector, which is then attached to a small, circular, planar adhesive dressing (a.k.a., drape). All of these connections are made air-tight during its manufacture. The tubing does not travel beyond the plane of the adhesive dressing, and therefore its opening remains at the skin surface. When the T.R.A.C. Pad is used, the standard dressing is initially applied to the wound, without a tubing connection. Then, a small incision is made in the dressing, over the wound cavity; this hole may also be prefabricated into the drape component of the dressing during its manufacture. The film backing of the circular adhesive component is removed from the Pad, and the tube opening is centered over the incision. Since the adhesive surface of the Pad is small, it is easier to handle than the procedure of tunneling the tube into the initial dressing. Although the Pad does not guarantee elimination of air leaks at the tube-to-dressing interface, it highly reduces the probable amount of air leaks into the dressing, based on its ergonomic design and small profile. A minimal amount of air leaks is almost unavoidable for all applications with planar adhesive components, due to the geometrical mismatch and user handling that still remain.

[018] Many efforts have been made in order to overcome the identified barriers of low end, mechanical pumps for application in NPWT. Most of the focus has been on reducing air leaks and creating more predictable vacuum sources. New materials used in NPWT dressings have been the main driver in reducing the air leak rate into the system at the dressing-skin interface. These materials are often not new to wound dressings; however, they are new to NPWT. Pump design has been the focus of creating more predictable vacuum sources; mechanical components, such as linear or constant force springs, are often introduced into the system and maintain a more predictable behavior throughout therapy.

[019] Only one mechanical NPWT system is on the market today, but is not widely used: SNaP(R) Wound Care System by Spiracur (Sunnyvale, CA). The SNaP(R) Wound Care System uses a hydrocolloid dressing with specific mechanical connectors from the tube to the dressing, in order to accommodate for air leaks; the provided hydrocolloid dressing is relatively small in size. Hydrocolloids are used in many wound-dressing systems, and are a common trend in the NPWT market. They are stiffer and thicker than most common, adhesive, planar, NPWT specific dressings. This causes the dressing to fold onto itself less during its handling and application. However, it cannot accommodate for geometrical mismatch without creases, especially as the dressing surface area increases. Since the dressing is stiffer and thicker, these creases are difficult to seal in an air-tight manner, due to its increased bending stiffness. Therefore, hydrocolloids are often only applicable to smaller wounds. Much effort is currently being taken to make them thinner, in order to increase their applicable surface area and accommodate more for contours, such as the Replicare Thin Hydrocolloid Dressing by Smith and Nephew. Hydrocolloids rely on their extremely sticky adhesive properties to account for increased skin adhesion and reduced air leaks. If they come in contact with wound exudate, the polymers in the hydrocolloid swell with water until saturation, forming a gel, which is held

solid in its adhesive matrix structure.

[020] In the SNaP(R) Wound Care System, the hydrocolloid dressings are connected to the tubing with a mechanical connector component, similar to the T.R.A.C. Pad, KCI. The SNaP(R) Wound Care System eliminates any potential air leaks from this mechanical connector by prefabricating it to the center of the entire dressing during manufacture. The prefabrication eliminates any potential air leaks at the tube-to-dressing interface due to user interface and geometrical mismatch, but it is not capable of being moved on the dressing surface. Therefore, it may need to be placed on an inconvenient area of the wound, such as a location that is uncomfortable for the patient. Additionally, the tube runs parallel to the plane of the drape; the direction of the tube along the plane of the drape is fixed. Since the dressings are not typically round, the tube path may be required to travel in an undesirable path, in order to cover the wound area with the preset shape of the drape.

[021] For its vacuum source, the SNaP(R) Wound Care System uses a complex system, driven by constant force springs. Therefore, as the pump expands, mainly due to air leaks and potentially exudate removal, the pressure remains relatively constant for the length of the pressure application. This system is expensive and highly technical when compared to the non-electrical pumps at the low end of the medical pump spectrum (e.g., bladder pumps); however, it is the first commercial mechanical NPWT pump, which has been proven to be a potential NPWT pump design. Since air leaks into the dressing system remain highly probable, depending on wound location and caregiver experience, the successful application of the SNaP(R) Wound Care System is limited in practice.

SUMMARY

[022] Occlusive skin dressings according to the present invention preferably provide one or more of the following advantages:

<-> a conformable dressing system that can be altered if desired and applied to substantially all areas of the skin surface;

<-> a dressing system that is ergonomic;

<-> dressings that are easy to obtain and re-obtain by the user, through conveniences in storage;

<-> dressings, pumps, systems, and methods to administer NPWT without the need for electrical power;

<-> minimizing the amount of air leaks into the NPWT system;

<-> detecting air leaks into the NPWT system;

<-> compatible with light-weight, easily transportable and low cost pumps; and

<-> mechanical methods to minimize the possibility of exsanguinating the patient.

[023] Occlusive dressings according to the present invention overcome the aforementioned drawbacks by being truly air-tight. One principal application of this technology is to facilitate administration of mechanical NPWT. A liquid component is applied at the dressing-to-skin interface in order to create a substantially air-tight seal preferably for at least 48 hours, more preferably for at least 72 hours. Preferably the same or different liquid component is applied at the tube-to-dressing interface in order to create a similar air-tight seal. In some embodiments, the liquid components may be made of rubber polymers applied by touch, by squeezing a dispenser, or by spraying the polymers with an atomization process.

[024] This invention features a kit suitable for occlusively sealing a wound penetrating the skin of a patient, including a drape formed as a thin sheet of an organic, preferably elastomeric material, substantially impervious to fluid transfer of air and bodily fluids, having first and second surfaces. A biocompatible adhesive is at least one of (1) disposed on at least the first surface of the drape and (2) capable of contacting at least a portion of at least the first surface of the drape. When the kit includes the biocompatible adhesive disposed on at least a portion of the first surface of the drape, the kit further includes at least a first

removable liner sheet covering the first surface of the drape. In some embodiments, a second removable liner sheet covers the second surface of the drape, especially when adhesive is also disposed on the second surface of the drape. The kit further includes at least one container of at least one sealant component that is capable of being delivered as a sealant in a liquid state at pre-selected ambient conditions, the sealant as delivered being at least partially cross-linked at least after one of drying and curing, and which is capable of at least one of drying and curing within thirty minutes, preferably within twenty minutes and, more preferably, within ten minutes, after application of the sealant as a layer to the edges of the drape after the drape is applied to the skin surrounding the wound.

[025] In some embodiments, the drape and the sealant after one of drying and curing are elastomeric. In a number of embodiments, the drape and the sealant are derived from substantially the same material, such as a type of a latex compound or a type of silicone compound. In certain embodiments, the adhesive is a silicone-based adhesive and is disposed on at least a majority of each of the first and second surfaces of the drape as a solid coating or in a pattern such as a grid or concentric circles. At least one container of a sealant component enables manual application of the sealant in some embodiments, such as by squeezing the container and, in other embodiments, at least one container is a removable vial or cartridge insertable into a dispensing apparatus or other applicator. In a number of embodiments, the kit further includes a flexible tube having a first end and a second end connectable to a source of negative pressure such as a bellows, especially a novel bellows which unrolls, or other mechanical vacuum source. Preferably, the kit further includes a flange having at least one of (1) a central passage through which the first end of the tube is insertable and (2) a central passage communicating with a connector capable of mating with the first end of the tube. In one embodiment, the first end of the tube includes a feature such as a spiral cut to resist blockage of the tube. In some embodiments, the kit includes at least one non-stick handling component. In a number of embodiments, the kit further includes at least one wound packing material.

[026] This invention may also be expressed as a method of constructing an occlusive dressing over a wound penetrating the skin of a patient by selecting a drape formed as a thin sheet of an elastomeric material, substantially impervious to fluid transfer, and having first and second surfaces. A biocompatible adhesive is selected that is at least one of (1) disposed on at least the first surface of the drape, preferably with a first removable liner sheet covering the first surface of the drape and (2) applied to at least one of (i) the skin of the patient surrounding the wound and (ii) at least a portion of at least the first surface of the drape. Optionally, a second removable liner sheet covers the second surface of the drape. The method includes removing the first removable liner, if present, and placing the drape onto the skin surrounding the wound, removing the second removable liner if present, and applying a sealant that is in a liquid state as applied, the sealant being at least partially cross-linked at least after one of drying and curing, on at least the edges of the drape and on the skin adjacent to the drape in one or more layers. The method further includes at least one of drying and curing the sealant within thirty minutes, preferably within twenty minutes, after application of the sealant to the edges of the drape in at least one layer.

[027] In certain embodiments, the adhesive is disposed on at least a majority of each of the first and second surfaces of the drape, and/or the method includes pressing on the second surface of the drape in the vicinity of any wrinkles in the drape, preferably before sealant is applied in that vicinity. In some embodiments, a flexible tube is selected having a first end and a second end connectable to a source of negative pressure such as a bellows or other mechanical vacuum source. Preferably, the first end of the tube (1) is inserted through a central passage of a flange secured to the drape or (2) is mated with a connector on a flange having a central passage communicating with the connector. In one embodiment, the first end of the tube includes a feature such as a spiral cut to resist blockage of the tube. In some embodiments, the wound is packed with gauze or other fluid-pervious material prior to placing the drape on the skin.

[028] This invention may be further expressed as a method of constructing an occlusive dressing over a wound, penetrating the skin of a patient, by at least one of (1) packing the wound with a fluid-pervious material and (2) covering at least a portion of the wound with a protective material. The method further includes applying, such as by spraying, an elastomeric material that is in a liquid state, and is at least partially cross-linked at least after one of drying and curing, over the packed material and onto skin surrounding the wound to create an occlusive drape as a thin sheet substantially impervious to fluid transfer, having a first, inner surface and a second, outer surface. The method includes at least one of drying and curing the elastomeric material within thirty minutes after application of the elastomeric material as a layer.

BRIEF DESCRIPTION OF THE DRAWINGS

[029] In what follows, preferred embodiments of the invention are explained in more detail with reference to the drawings, in which:

[030] FIG. 1 is a schematic expanded perspective view of a drape, flange and tube with first and second liners prior to application of a liquid sealant according to the present invention;

[031] FIGS. 2 and 3 illustrate a novel first end of the tube of FIG. 1 being inserted through the novel, preferably symmetrical flange;

[032] FIG. 4 is a schematic perspective view of an alternative novel first end of a tube;

[033] FIGS. 5A and 5B illustrate repositioning of the upright tube into a desired side orientation;

[034] FIGS. 6 and 7 show a drape being covered by an upper liner to manufacture a dressing according to the present invention;

[035] FIG. 8 shows a hole punched in the dressing of FIG. 7;

[036] FIGS. 9 and 10 shows a tube assembly being inserted onto the dressing of FIG. 8 with the edge of the flange being sealed to the drape;

[037] FIG. 11 shows a protective liner being added to the dressing of FIG. 10;

[038] FIG. 12 illustrates how a user can cut the dressing of FIG. 11 to conform to a wound;

[039] FIG. 13 shows a handling tab being added to the dressing of FIG. 12;

[040] FIGS. 14 and 15 illustrate debriding and packing an open wound;

[041] FIG. 16 is a perspective view of the underside of the dressing of FIG. 1 1 with the bottom, inner protective layer being removed;

[042] FIG. 17 is a schematic top plan view of a dressing according to the present invention attached to skin surrounding the wound;

[043] FIG. 18 is a schematic perspective view of the dressing of FIG. 17 with the upper protective liner being removed;

[044] FIG. 19 shows liquid sealant being applied to the edges of the drape of FIG. 18;

[045] FIGS. 19A and 19B illustrate modifying the coverage of a dressing according to the present invention;

[046] FIG. 20 is a schematic expanded view of a vial of sealant with a non-stick finger protector optionally positionable within the vial for storage and transportation;

[047] FIGS. 21 A and 2 IB show a dispensing apparatus with removable cartridge of liquid sealant;

[048] FIG. 22 is an enlarged perspective view of the cartridge of FIGS. 21 A and 21B;

[049] FIG. 23A is schematic perspective view of a hand-powered squeeze applicator for liquid sealant;

[050] FIGS. 23B and 23C are enlarged views of the outlet with and without a removable strip covering the dispensing openings;

[051] FIGS. 24 and 25 are schematic top plan views illustrating non-stick gloves and finger covers, respectively, integrated into a liner;

[052] FIGS. 26-28 are schematic top plan views liners having different shapes;

[053] FIG. 29 is a schematic side view of a dressing according to the present invention being applied to the heel of a foot;

[054] FIGS. 30 and 30A are enlarged schematic views of the dressing of FIG. 29 with a fold being created and then pressed flat to enhance conformance to the heel;

[055] FIG. 31 is a cross-sectional view of a known bellows pump;

[056] FIG. 32 is a perspective view of a novel rolling bellows pump;

[057] FIG. 33 is a flow chart of a sample occlusive dressing method;

[058] FIGS. 34 A and B are diagrams comparing active versus passive flow NPWT systems;

[059] FIG. 35 is a diagram of a method to prevent undermining of the dressing due to exudate build-up in the passive NPWT system;

[060] FIG. 36 is a diagram of some of the specific components of an occlusive wound dressing embodiment;

[061] FIG. 37 is a diagram of a tube connection method with a spiral end tube;

[062] FIG. 38 is a schematic top plan view of the wound shown in FIG. 14 with the additional step of applying a protective covering over the wound;

[063] FIG. 39 is a view of FIG. 38 with a hole cut in the protective covering;

[064] FIG. 40 is a view of FIG. 39 with a tube assembly placed over the hole;

[065] FIG. 41 is a view of FIG. 40 with liquid drape material applied over the protective covering and onto surrounding skin to construct a dressing according to the present invention;

[066] FIG. 42 is a schematic perspective view of the dressing of FIG. 41; and

[067] FIG. 43 is a schematic perspective view of a novel flange according to the present invention with integral connector.

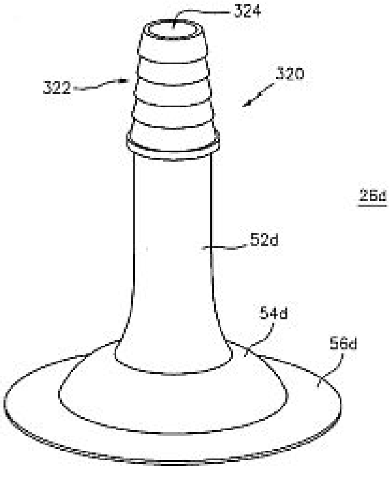

FIG. 43

DETAILED DESCRIPTION

[068] This invention may be accomplished by a kit, dressing system or method utilizing a drape formed as a thin sheet of an organic, preferably elastomeric material, substantially impervious to fluid transfer of air and bodily fluids for preferably at least 48 hours, more preferably at least 72 hours, having first and second surfaces. Preferably, a biocompatible adhesive is disposed on, applied to or contacted with, at least the first surface of the drape. In a number of constructions, a first removable liner sheet covers the first surface of the drape and, optionally, a second removable liner sheet covers the second surface of the drape. The invention further utilizes a container of at least one sealant component that is capable of being delivered as a sealant in a liquid state at pre-selected ambient conditions, the sealant as delivered being at least partially cross-linked at least after one of drying and curing, and which is capable of at least one of drying and curing within thirty minutes, preferably within twenty minutes and, more preferably, within ten minutes after application of the sealant as a layer to the edges of the drape after the drape is applied to the skin surrounding the wound.

[069] The occlusive dressings presently disclosed address the power/mobility and air leak issues by eliminating the need for an electrical power source and by maintaining reliably air-tight interfaces, particularly at 1) the dressing and the skin and 2) the tube and the dressing. The disclosed dressing systems and their connection methods allow for reliable, mechanical NPWT systems. Not only does this eliminate patient mobility and battery management issues, but it also allows NPWT to be administered in austere environments, where electricity is often scarce and harsh environments require robust products. Multiple disclosed embodiments support an inexpensive, robust therapy method for global application. Additionally, dressings according to the present invention are MRI- compatible.

[070] In order to obtain an air-tight skin dressing, the present occlusive dressings use a liquid sealant. This liquid sealant may dry and cure fast, even immediately or effectively immediately, upon application to the skin or other dressing components, into a continuous, occlusive film or sheet of material. The drying and curing processes may occur simultaneously, may be driven by evaporation, may require a curing agent and/or accelerator, and/or may be enhanced or controlled with a curing agent and/or accelerator. Any extra

additives (e.g., curing agents and accelerators) may be added just before, during, and/or after the sealant application process, depending on its chemical reaction with the sealant and its rate.

[071] The liquid sealant bonds to the component(s) that it is meant to seal. The ability of Van der Waals forces to provide the bond strength without an added adhesive is based on the material and its thickness. Theoretically, the debond toughness (strength of the bond) must be greater than the debonding energy, and the debonding energy is proportional to: the thickness of the material, the strain in the material squared, and the elastic modulus of the material. Specifically (on a first order basis; as its basis is a small strain analysis), the bond strength of a thin film must abide by Equation 1, where [Gamma] is the debond toughness, [sigma] is the debonding energy, [Omega] is a dimensionless prefactor, h is the thickness of the film, [epsilon][tau] is the strain in tension, and Ef is the elastic modulus of the film, in order to maintain adhesion to the skin in tension:

[Gamma] > [sigma] = [Omega]1[iota][epsilon][tau][3/4](1)

Therefore, a highly elastic, thin film presents the ideal material properties for reduced, required adhesion strength, increasing the functional applicability of the Van der Waals forces.

[072] An additional adhesive, such as a silicone-based, latex-based, or acrylic- based glue, having one or more components, might be employed to produce the desired bond strength (for example, Liqui-Tape Silicone Adhesive, Waterproof by Walker Tape Co., West Jordan, UT). This adhesive can be applied under the liquid sealant or chemically mixed with the liquid sealant prior to its application, depending on its chemical make-up and final mixing properties. When applied under the sealant, the adhesive may need to become tacky (a.k.a., applied set time) prior to sealant overlay. A fast-setting, two-part sealant that is mixed prior to use may be useful in some circumstances, such as Skin Tite(R) silicone available from Smooth On, Easton, Pennsylvania, which is ACMI Certified Safe and may be used by itself or mixed with a thickener, such as Thi-vex(R) thickener, also available from Smooth On. A polymer sealant, or other material with the ability to bond into a continuous occlusive sheet, with adhesive-like properties due to high Van der Waals forces may be desirable, where no additional adhesive is needed.

[073] Rubber polymers, such as latex, synthetic rubber, and hypoallergenic latex, are examples of polymers with desired properties for both the dressing-to-skin and tube-to- dressing interfaces. For example, Deviant Liquid Latex from Deviant, a subsidiary of Envision Design, San Jose, CA and Liquid Latex Fashions Body Paint from Liquid Latex Fashions, Warrington, PA were both demonstrated to seal the dressing at both dressing interfaces. The drying and curing time for the latex was significantly reduced by applying the liquid to the skin with an atomization process, which is further disclosed in the sections below, by adding alcohol, which helps to absorb the water that evaporates from the latex, and/or by flowing a gas across the sealant for convection drying. For most applications, the curing/drying time was lowered to immediately (at most 1 minute) from the 5-10 minutes previously stated by Deviant at http://www.liquidlatex.net/.

[074] Examples of suitable latex materials include Vytex Natural Rubber Latex (NRL), a brand of natural rubber latex produced and marketed by Vystar Corporation, Duluth, GA. Vytex is manufactured by Revertex Malaysia and distributed by Centrotrade Minerals and Metals, Inc. Protein test results show that Vytex NRL typically has 90% fewer antigenic proteins than Hevea natural rubber latex. Therefore, Vytex causes less exposure and developed latex sensitivities. The Vytex has two products with different levels of ammonia; ammonia is a stabilizer and preservative, and both functionally are feasible for the NPWT liquid sealant and drape components, although alternative stabilizers to ammonia may irritate the skin less. Liquid latex for body painting typically contains ammonia, which is what has been applied to patients during field studies with no irritations. Vytex NRL, low ammonia compound, has provided functional, occlusive drape and sealant components on clean, unwounded skin in a lab setting.

[075] Yulex Corporation, Phoenix, AZ creates hypoallergenic latex from guayule (Parthenium argentatum). Yulex's guayule biorubber emulsions and solids have none of the sensitizing antigenic proteins found in traditional Hevea latex and is considered a safe alternative for people with Type I allergies. Yulex's biorubber emulsions are registered with the Personal Care Product Council and its INCI name is Parthenium argentatum Bark Extract. This is a presently preferred material for the NPWT dressing and sealant, in order to provide a non-allergenic material option. Yulex presently has ammonia and ammonia-free options.

[076] Synthetic materials such as nitrile rubber and neoprene are alternatives to natural rubber that do not have allergy-provoking proteins, but can also generally have poor elasticity with higher risk of break rates and viral penetration rates. Therefore, they are less ideal for many of the dressing applications according to the present invention, but may be suitable in some circumstances, particularly for the drape for which curing on the skin and drying time are not issues. Other multi-part materials, such as Room Temperature Vulcanizing silicones and certain polyurethanes which are two-part materials with base and curative components, may be acceptable in some applications.

[077] Extremely low stiffness, which is achievable with many rubber-type materials, increases its bonding ability through Van der Waals forces alone. The high elasticity capable of being achieved using rubber polymers accommodates for the high levels of tensional strain reached at the skin surface during large deformation body movements. Additionally, the material properties of rubber polymers may also accommodate for the tendency to buckle when compressive strains are applied, depending on any initial interface crack sizes and adhesion strength. A desirable sealant accommodates for the large variability over time and surface area of the skin surface strains experienced during large deformation human motions; in the literature, the maximum large deformation strain is indicated to be approximately 0.45 in tension and 0.3 in compression. As rubber mechanical properties are sufficient to achieve structural integrity, the Van der Waals adhesive properties determine the applicable occlusive sealants, and depending on the polymer, an additional adhesive may be necessary.

[078] The liquid sealant should have viscosity and curing properties, preferably including minimal shrinkage, that enable it to conform to all contact surfaces during the application and curing processes, such that no air leak channels at the interface are present after its application. At the dressing-to-skin interface, the sealant should conform to the folds and creases in the skin that are often bridged when applying a standard, planar wound dressing. These types of bridged cracks at all component interfaces are often a significant source of air leaks into the system without a liquid sealant. Once a crack exists, crack propagation occurs in tension and compression with reduced, applied strains, so air leak channels can form overtime with reduced strain magnitudes. Therefore, eliminating any initial cracks at all of the interfaces is desirable. At the dressing-to-skin interface, structures, such as hair, often create opportunities for crack propagation and air leaks into a wound dressing, and therefore, hair is often shaved before dressing applications. The need to shave the hair from an infectious standpoint is not desirable, as the shaving process creates trauma at the hair follicles and increases the risk of infection. With a liquid sealant, these structures can be completely enclosed in the air-tight sealant, and therefore, are not a source of crack propagation under the sealant and do not typically require removal prior to the sealant application, as cracks at the dressing edges are most critical to seal, in order to resist crack propagation due to tension. In some constructions, adhesive on the first surface of the drape is sufficiently thick and/or flowable to seal around hairs and skin crevices and to minimize crack propagation.

[079] The sealant thickness, number of components, wound location, and sealant viscosity determines the optimal sealant application method(s). The liquid sealant may have a very high to low viscosity, as long as it can completely wet the contact surfaces. If mechanically applied (e.g., brush or "painting" application, roller application, sponge/dabbing application, squeegee or other squeeze-type application, application by-hand (i.e., finger) with or without a non-stick cover, etc.), a viscosity that avoids run-off due to gravity is preferable in order for the sealant to be ergonomically applicable to any wound location. This leads to higher viscosities and is limited at the low viscosity range. Painting is not the preferred application method; when painting the sealant, it is difficult to achieve a constant thickness. If the thickness varies significantly over its surface area, the mechanical properties and debonding energy will also vary significantly, which may cause occlusive dressing failure. Painting also has other drawbacks, as it is easy to trap air bubbles in the sealant, which are a source of cracks for crack propagation. Also, it is difficult to produce and maintain a very thin coat, which significantly increases the necessary Van der Waals bonding strength; it increases the stiffness of the final dressing and decreases its ability to conform to large tissue strains.

[080] Spraying is a preferred method of applying the sealant. Two types of spraying procedures are possible: 1) an aerosol process which propels the liquid sealant with a pressurized liquid or gas propellant that forces the liquid sealant through an atomizing nozzle, and 2) a shearing process which shears the liquid sealant with a pressurized gas or liquid causing atomization. When atomized, the layer of sealant material can be made thin enough that run-off is less of an issue, and therefore a range of lower viscosities can be used for their desired wetting characteristics. Additionally and in combination, the small atomized particles

fill in the structures on the skin for wetting purposes. The spraying technique is limited at the high viscosity range, as too high of a viscosity sealant will not be capable of being sprayed with reasonable pressures and velocities for application in the clinical setting onto skin. However, this is not seen as a negative aspect since liquids with very high viscosities often do not properly wet the complex contours of the skin surface.

[081] The shearing process may be preferred over the aerosol process. One reason for this preference is that nozzles clog easily with long polymer chains, unless the liquid can be further thinned. Using the shearing process, the shearing fluid and sealant fluid may be kept separate until they are both external to the nozzle head. Therefore, internal clogging of the nozzle does not occur when properly designed, including a fluid filter (if necessary) and the proper nozzle orifice size. Gas is the preferred shearing fluid, as it does not add additional liquid to the system for drying purposes, it is easy to propel since it can be compressed to high pressure levels, and it helps to dry the sealant when spraying it onto the skin. Higher viscosities and materials with long polymer chains are capable of being sprayed by the shearing method rather than the propellant method, although the viscosities and chemical chains that can be accommodated with the propellant method can be increased with complex nozzle design.

[082] Additives such as curing agents, accelerators, convection drying agents, and adhesives may be applied via separate application methods, if they are not mixed with the sealant prior to application. Their application method may be via painting or spraying. The application of these additive components and the sealant may occur in a multi-step process. They may be stored and applied from separate containers with the same or different application methods in series or in parallel. However, they may also be applied in parallel or series from the same containing body. One example is a parallel spraying process, for which three ports exist: the sealant port, the shearing fluid port, and an accelerator port; these three components can combine during the atomization process in the spray nozzle where the three ports may interact. Another example is a spray apparatus that allows the amount of sealant (and potential accelerator) to be controlled, such that it may be shut-off; the shearing gas then becomes a convective drying gas.

[083] Various polymers with rubber-like properties were determined to have the desired sealant properties. Additionally, a preferred sealant cures immediately or within a few seconds after surface contact. With these characteristics, the polymer tends to have long and heavy polymer chains, and therefore, requires the higher atomizing forces capable with the shearing process. As gas is used to atomize the polymer, there is a desirable range of gas pressure, velocity, and volume flow combinations that are required for the desired, continuous-film outcome. Filtered air, pure oxygen, and carbon dioxide are examples of applicable shearing gases that can be readily used, and are often available in the clinical setting at the desired pressures and volume flow rates. They are also readily available outside the clinical setting. Using these gases, the necessary, shearing atomization process is capable of being designed into a miniaturized handheld device. This process and design is similar to the consumer use of the aerosol embodiment commonly found in consumer products and is further disclosed in the Dressing

Application Methods section.

[084] The thickness of a desired seal embodiment can be built-up in a successive layered, lamination process. A material that has a strong affinity for itself with either strong Van der Waals forces or chemical bonds that form between its layers, such that the final material behaves as a continuous one-layer sealant is desirable. The desired thickness is the minimal thickness needed for strength and to achieve the desired occlusive properties, which is material dependent. This thickness is often thinner than the thickness that can be reliably and uniformly achieved through a painting process, and therefore a spraying process is often preferred. The atomization process provides a method to achieve the thinnest functional sealant thickness.

[085] Occlusive dressings are beneficial beyond NPWT and in combination with advanced NPWT features. Some proven benefits of occlusive properties are highlighted here. The occlusive characteristic may enhance the penetration and absorption of topically applied medications, such as ointments, powders and creams, which can be beneficial in combination with standard wound dressings and with therapies, such as NPWT. The V.A.C. Instill Therapy Unit (KCI) was meant to combine instillation therapy with NPWT. Instillation, as defined by the V.A.C. Instill documentation, includes both: 1) the introduction and removal of topical solutions in liquid form and 2) the ability to flush out and clean a wound through a rigorous irrigation technique. The main caregiver complaint about this and other instillation-purposed dressings is that they often leak liquid during the instillation process, especially during a rigorous irrigation procedure,

which further induces air leaks during continued therapy. The occlusive seal and dressings disclosed in this disclosure would solve any leak issues that arise. Often the irrigation process introduces leaks by propagating cracks in the dressing; by eliminating these cracks, the sealant and dressing techniques in this disclosure significantly reduce the potential for leaks and leak formation during instillation. The port(s) needed for instillation fluid insertion and removal can be directly connected to the disclosed occlusive dressing embodiments with the same tube-to-dressing connection methods that are disclosed in the Tube-to-Dressing Interface section in this disclosure.

[086] Although the presently disclosed occlusive dressings were developed with NPWT system in mind, they can be used for any application for which an occlusive (a.k.a., air tight and water tight), air tight, or water tight seal to the skin is desirable. Therefore, they are applicable in multiple fields beyond NPWT, and more generally in the field of skin sealants and their methods. Truly occlusive dressings create a control volume over the area of tissue that they are applied, which is a desirable feature for multiple applications, many which are disclosed in this application document.

[087] The occlusive dressings discussed in this disclosure are the first skin dressings to provide a control volume, as no other dressing to-date is proven to be (reliably) truly occlusive. This would benefit the enhancement of advanced healing therapies that are sensitive to any variation in the environment, such as stem cell based therapies, for which complete control of the environment is necessary to achieve deterministic results. If a specific air leak is desirable, its rate can be precisely controlled into the control volume through precision valves. Currently, there is no accurate predetermination for the air leak rate into any wound dressing, especially since most dressing air leaks have variability over time and with body movement. Furthermore, truly occlusive dressings may be used in in vivo acute toxicity tests of dermal irritation and sensitization. The test animal is shaved and the test material is applied to the skin and wrapped in an occlusive material. The skin is then exposed after 23 hours and an assessment for redness and edema is made; this assessment is repeated 48 hours later. [088] FIG. 1 is a schematic expanded perspective view of a dressing assembly 20 including a drape 22, a novel flange 26 and a tube 24 with first and second protective liners 28 and 30 prior to application of a liquid sealant according to the present invention. Drape 22 and second liner 30 define holes 32 and 34, respectively, through which tube 24 is insertable.

[089] FIGS. 2 and 3 illustrate a novel first end 40 of the tube 24 of FIG. 1 being inserted through the novel symmetrical flange 26 to form a tube assembly 27, FIG. 3. First end 40, also referred to as distal end 40, includes a spiral extension 42 which, in one construction, is formed by making a helical cut into the distal end of tube 24. In other constructions, a separate component having a helical shape or other geometric shape is attached to serve as a deterrent to clogging of distal end 40. Spiral extension 42 minimizes possible blockage of lumen 46 through tube 24. Another anti-blockage construction is illustrated in FIG. 4 with a tube distal end 60 defining perforations 62 and 64, notches 66 and 68, and a blunt tip 70. Perforations 62 and 64 can be formed as diamond-shaped cutouts, circular holes, or other geometries. A notch 44, FIG. 2, is also created in this construction to further minimize the possibility for lumen 46 through tube 24 to become obstructed, as described in more detail below.

[090] Arrow 48, FIG. 2, represents distal end 40 being inserted through passage 50 in flange 26 defined by a sleeve region 52, a rotation region 54, and an adhesion region 56 having an outer edge 57. Sleeve region 52 is adhered to tube 24, as described in more detail below, at a final location such as shown in FIG. 3. In another construction, sleeve region 52 is attached, via adhesion, welding or other air-tight connection process, to a short piece of tube with a connector that connects to a longer piece of tubing. In yet another construction, the flange includes an integral connector capable of mating with flexible tubing such as shown in FIG. 43. Rotation region 54 serves as a flexible ball joint in this construction. As depicted in FIGS. 5A and 5B, tube 24 can be manipulated in the direction of arrow 72, FIG. 5A, to a desired side orientation as shown in FIG. 5B. Lumen 46 through tube 24 remains open in some constructions because distal end 40 extends beyond adhesion region 56, with notch 44 preferably below sleeve region 52 but above adhesion region 56, so that rotation region 54 does not collapse onto itself. In other constructions, the flange is sufficiently short and wide to minimize the possibility of pinching closed. Sleeve region 52 is sealed in an airtight, fluid-impervious manner in some constructions by first applying a silicone adhesive, such as Liqui-Tape adhesive from Walker Tape Company as mentioned above, to the portion of the outer surface of tube 24 which will be brought in contact with sleeve region 52 during assembly. A liquid sealant can be applied to the junction of tube 24 and flange sleeve region 52 to further occlude possible fluid escape at that junction.

[091] In some constructions, flange 26 is manufactured directly onto tube 24, via a dipping, molding or spraying process. In constructions where flange 26 is constructed entirely from, or coated with, a material that has an affinity for itself, sleeve region 52 may self-adhere to rotation region 54 and adhesion region 56, to the extent that region 56 is exposed, when folded against itself as shown in FIG. 5B. Where the material forming the exterior of flange 26 has an affinity for the material of drape 22, especially for materials containing latex compounds, the exterior of sleeve region 52 will also adhere to drape 22 at least to some extent; latex-type material applied to the surface of tube 24 will further enhance this adhesion. Fixing the tube 24 into a fixed orientation such as shown in FIG. 5B may be especially beneficial for bed-ridden or less mobile patients so that the tube can be positioned to avoid the patient lying on the tubing for long periods of time or to avoid compromised areas around the wound. In other circumstances where the tube remains movable, it can be easily repositioned because rotation region 54 remains flexible and the tube can be monitored and moved frequently to assure that tissue is not degraded from lying on the tube in one position for an extended period. Especially for active patients, the tube 24 can be periodically re-positioned by the patient or by a healthcare professional.

[092] FIGS. 6 and 7 show a drape 22 being covered by an upper liner 30 to manufacture a dressing according to the present invention. Preferably, drape 22 has a thickness ranging from 2 microns to 0.4mm, especially in portions which will be applied to skin; a greater thickness in the center portion to be located over a wound is less critical for occlusivity. In some constructions, adhesive is pre-applied on the upward-facing surface shown in FIGS 6 and 7, which will be placed in contact with skin during use; in other constructions, adhesive is also placed on the opposite side of drape 22, to be covered by liner 30, as indicated by arrow 81 in FIG. 6, for storage and handling. The adhesive is applied as a uniform coating in some constructions and, in other constructions, as concentric circles or other non-uniform pattern. Preferably, liner 30 has extensions 82 and 84 which extend beyond the drape 22 to facilitate handling of the dressing without touching any adhesive, and to enable easy removal of the liner 30 from the drape 22 after placement on a patient.

[093] FIG. 8 shows a hole 32 punched in both layers of the dressing of FIG. 7.

Hole 34, FIG. 1 , is not visible in FIG. 8.

[094] FIGS. 9 and 10 shows a tube assembly 27 being inserted, arrow 90, onto the dressing of FIG. 8 with the adhesive region 56 to edge 57 of the flange 26 being sealed to the drape 22 utilizing the pre-applied adhesive. Additional adhesive or sealant can be added around edge 57 or pre-applied to region 56 as desired.

[095] FIG. 11 shows a protective liner 28 being added to the dressing 20 of FIG.10. Protective liner 28 protects the skin-side adhesive, when pre-applied, until liner 28 is removed as illustrated in FIG. 16 below. Distal end 40 with anti-clogging feature 42 is sufficiently relaxed and short in length to be contained under liner 28. Liner 28 preferably extends beyond drape 22 over regions 82 and 84 of liner 30.

[096] FIG. 12 illustrates how a user can cut the dressing 20 of FIG. 11, along dashed line 92 using scissors 93 for example, to conform to a wound.

[097] FIG. 13 shows a handling tab 94 being added, arrow 96, to the dressing 20 of FIG. 12, which is especially useful if liner extensions 82 and 84 are cut away. In this construction, tab 94 is attached by adhesive 95 to one of liners 28 and 30 to assist removal of the selected liner. Additionally or as an alternative, perforations 97, 98 create locations for easy removal of the liners. If perforations are utilized, it is preferred that the top and bottom liners have perforations that are aligned along different angles. The preferred angle difference is substantially perpendicular, that is, at about ninety degrees offset. Perforations are preferred when extensions 82, 84 are not provided. The dressings are very difficult to handle with medical gloves on, which are required for sterility. Therefore, handling tabs eliminate the need for the clinician to touch the adhesive. This is also desirable since powdered gloves tend to cause the adhesive to adhere to the powder and loose its adhesion properties. Another solution would be to provide non-stick finger or hand covers, such as shown in FIGS. 24 and 25, similar to the finger sealant applicator shown in FIG. 20. This is especially important when dressings are re-shaped, potentially cutting off handling features, and when the user is removing the top protective liner and folding down the top folds. Ideally, additional handling components are built into the packaging components or protective liners. Such as, the package that

the drape comes in, turns inside out to form a sterile, handling glove, or the bottom liner is used to maneuver the higher-level of adhesive interactions when dealing with the top liner. The bottom liner may have a cut-out (pre-perforated) glove, FIG. 24, with the non-stick side, e.g. silicone-coated, initially facing the adhesive; preferably, a non-stick coating is provided on both sides for both right- or left- handed application.

[098] FIGS. 14 and 15 illustrate debriding an open wound W and cleaning the wound cavity and surrounding skin SK, preferably at least 3 cm in width as indicated by dashed line 102, with standard cleaning methods such as with alcohol and gauze wipes. Typically, the next step is to pack the open wound W with fluid pervious material 104 such as gauze, open-cell foam or a sponge.

[099] FIG. 16 is a perspective view of the underside of the dressing 20 of FIG. 11 with the liner 28 being removed as indicated by arrow 106, such as by pulling on corner 108, to expose drape 22 with pre-applied adhesive.

[0100] FIG. 17 is a schematic top plan view of a dressing 20 according to the present invention attached via adhesive drape 22 to skin SK surrounding the wound. When negative pressure therapy is desired, a source of negative pressure is connected to tube 24 such that its lumen is in communication with the wound cavity.

[0101] FIG. 18 is a schematic perspective view of the dressing 20 of FIG. 17 with the upper protective liner 30 being removed, as indicated by arrow 110. Dashed line 112 represents a perforation or pre-cut line to assist removal of liner 30 without sliding it over tube 24.

[0102] FIG. 19 shows liquid sealant 114 being applied to the edges of the drape 22 of FIG. 18. The preferred sealant embodiment has as width of 2-3cm and is centered over the edge of the drape 22.

[0103] If the dressing is applied to contoured surfaces on the body, such as described below in relation to FIGS. 29-3 OA, folds in the planar dressing may be necessary for adhering to the surface of the skin, in order to match the surface contour. These folds typically travel from the outer edge towards the tube 24. In this situation, the preferred application method is to minimize the number of folds by creating a few large folds. Preferably, there are no more than four folds, divided substantially equally around the periphery of tube 24. These folds are created when adhering the drape to the surface of the skin, forming a "T". Then, when the top protective liner is removed, the folds are adhered to the surface of the drape with the adhesive on the top of the drape. Preferably, the folds form individual triangles on the top surface of the drape. The folds are then pressed to lie flat and be completely adhered to the surface of the drape. Sealant is then applied to the edge of each fold to seal off the area between the fold and the top of the drape from the surrounding environment. This additional sealant preferably connects with the sealant placed around the outer edge 114, FIG. 19, for example. Preferably, the additional sealant is applied at substantially the same time as the original sealant with the same sealant material. Any drape material that would extend onto the skin, beyond the original edge of the drape, when folded preferably is cut off before pressing the folded drape material against the skin to lie within the original edge of the drape. Patterns may be provided on the upper protective liner to direct the user where to put the folds, when needed.

[0104] FIGS. 19A and 19B illustrate modifying the coverage of a dressing 20a according to the present invention, with drape 22a, tube 24a and flange 26a. If the dressing 20a is too small to cover the desired skin area around the wound, preferably by 3 -5cm, for instance if the user cut away too much of the dressing, as shown by cut-out 120, while reshaping the drape for easier application or in order to avoid a complex contour near the wound cavity, the user can use sealant to reconstruct the dressing as shown by additional sealant 122, FIG. 19B. A modified occlusive dressing 20a is thereby achieved. However, it is preferable for the drape 22a itself to cover the entire wound edge, in order to protect the wound cavity from the sealant material.

[0105] FIG. 20 is a schematic expanded view of a vial 130 of sealant, with closure threads 131 to receive a cap 134, with a non-stick finger protector 132, shown in cross- sectional view, preferably with a rim 133, optionally positionable within the vial 130 for storage and transportation.

[0106] FIGS. 21A and 21B show a dispensing apparatus 140 with removable cartridge 150 of liquid sealant. Dispensing apparatus 140 has a finger trigger 142 and a nozzle 144 in this construction and can be powered by a cylinder of compressed gas, such as a C02 cartridge, contained within the housing 146. Preferably, the apparatus is gravity fed. Because there need not be a needle valve, such as found in typical air guns to stop the flow of fluid, an adhesive tab 152, FIG. 22, is initially removed from tip 154, and the cartridge 150 is inserted into the apparatus 140 as represented by arrow 149, FIG. 21B. A plug 156, FIG. 22, is then removed, such as by twisting, to expose an air hole at the top of cartridge 150 and activate apparatus 140 and allow sealant to flow or be sprayed out of nozzle 144. The apparatus 140 can be set aside temporarily, with nozzle 144 directed upwards, between sealant layer applications.

[0107] FIG. 22 is an enlarged perspective view of the cartridge of FIGS. 21 A and 2 IB with internal chamber 160, raised floor 162, and slope 164 in this construction to assist gravity feed of sealant liquid to tip 154, as indicated by arrow 166. In other constructions, a multi-component sealant is delivered utilizing a separate chamber for each component. The components are mixed during delivery in a down-stream mixing chamber or in a mixing nozzle such as the 3M(TM) Scotch- Weld(TM) EPX(TM) Mixing Nozzle currently available from 3M Company, St. Paul, Minnesota. Other multi-component delivery systems can be utilized such as those commercialized by Henkel Loctite Corporation, Rocky Hill, Connecticut. One or more of the sealant components can be a powder or other state as long as the final sealant is delivered in a liquid state, including as liquid droplets via shearing or a propellant.

[0108] FIG. 23A is schematic perspective view of a hand-powered squeeze applicator 170 for liquid sealant.

[0109] FIGS. 23B and 23C are enlarged views of the squeegee-type outlet 172 with and without a removable strip 174 covering the dispensing openings 176 of passages 178 communicating with inner chamber 180. In this construction, a removable tab 182, FIG. 23 A, allows air to enter chamber 180 during delivery of the sealant.

[0110] FIGS. 24 and 25 are schematic top plan views illustrating non-stick gloves 191 and finger covers 201 formed in liners 190 and 200, respectively. These applicators are non-stick, such as by a non-stick silicone coating, on only one side in some constructions and, in other constructions, are non-stick on two sides.

[0111] FIGS. 26-28 are schematic top plan views liners 210, 220 and 230 with indicator lines 212 and 214, 222 and 224, and 232 and 234, respectively, having different shapes for selected locations and contours of a patient. Shorter lines 222 and 234 have priority if folds are needed; a symmetrical shape such as a square or the circular shape of liner 210, FIG. 26, has fold lines of equal priority.

[0112] FIG. 29 is a schematic side view of a dressing 20b according to the present invention being applied to the heel H of a foot F. Flange 26b is positioned with tube 24b communicating with a wound in heel H. One large fold 240 is shown, with edges 244 and 246.

[0113] FIGS. 30 and 30A are enlarged schematic views of the dressing of FIG. 29 with a fold 240 being created and then pressed flat to enhance conformance to the heel. All edges 242, 244 and 246 should be sealed with sealant 248 according to the present invention.

[0114] There are multiple different methods of using the sealant described in this disclosure at the dressing-to-skin interface. The first method is to use the sealant in conjunction with current, commercial skin dressings (or dressings with similar embodiments), in order to achieve occlusive properties. In order to do this, the dressing is first applied to the skin, step 1502, FIG. 33, after the wound is packed, step 1501 ; typically, the dressing (a.k.a., drape component) is a planar adhesive tape form. The drainage tube may enter into the dressing at the dressing-to-skin interface, or it may have its own connector that requires an incision into the dressing above the wound cavity, step 1503. The dressing system is applied with its recommended procedure. Then, all dressing-to-skin interfaces are sealed with the sealant and potentially additional adhesive, step 1504.

[0115] At the dressing-to-skin interface, the sealant contact with the skin should be biocompatible. The sealant should conform to and seal off the folds and creases in the skin, which are often bridged when applying a standard, planar wound dressing. These cracks are a significant source of air leaks into the system without a liquid sealant with the proper wetting properties. The proper wetting properties are achieved by applying the liquid sealant directly to the skin and dressing in its liquid form through a painting process or through spraying the liquid with an atomization process that eliminates liquid run-off and that may achieve a more uniform, thin film.

[0116] Once a crack in the planar dressing exists, crack propagation may occur in tension and compression with reduced, applied strains. Therefore, sealing any initial cracks in the dressing-to-skin interface is desirable. Also, properly sealing the dressing-to-skin interface at the edge of the dressing deters any air leaks from future crack propagations, as the sealant hinders the propagation from reaching the outside environment. If an additional adhesive is used between the sealant and dressing-to-skin interface, then the adhesive should adhere to the skin, dressing, and sealant to form the necessary bond strength. The adhesive or its applied components should also conform to the folds and creases in the skin and/or dressing. The adhesive should be compatible with the skin, dressing, and sealant when applying the adhesive under the sealant, or when mixing the sealant with an adhesive component prior to application.

[0117] Use of the liquid sealant can permit elimination of the current commercial dressings (or similar dressing embodiments; a.k.a., the drape component). The liquid sealant can be applied directly over the wound cavity and wound packing material. In some embodiments, the packing material may require an additional liquid tight barrier if the liquid sealant can be absorbed into the packing material. Additionally, a liquid tight barrier may need to exist at the interface between the packing material and the wound edge, as the sealant could potentially leak into this barrier, depending on the application technique of the packing material, which may not be desirable. A gap at the interface between the packing material and the wound edge may be disruptive to the sealant in creating a continuously occlusive film, or the potential of the sealant contacting the inside tissue of the wound cavity may need to be eliminated. These barriers may be of an occlusive nature; in this case, the sealant should be applied at any of their non-occlusive edges; however, the sealant may also cover the entire surface area, which may help to maintain the adhesion of the barriers. The barriers can be made of multiple materials from adhesive and non-adhesive polymer films to clays and pastes, for example. Barriers mentioned in this description are different from the standard wound dressings, as the standard wound dressings' adhesion to the skin forms structural and adhesion integrities of the dressing-to-skin interface, and the barriers currently discussed are used to protect the wound from the sealant component and are not necessarily intended to provide any structural support beyond that purpose.

[0118] Maceration of the skin under a truly occlusive dressing may be of concern to the caregiver. This can be solved with a material selection solution, as a one-way, directional occlusive sealant material can be used that allows the skin to breathe and its moisture to evaporate without letting air into the system. Similar material properties are commonly found today in materials used for sports apparel. Additionally, this can be solved from a design perspective. The sealant application area can be made narrow enough that the moisture of the tissue under the dressing can diffuse around the seal. If a larger surface area of seal adhesion is necessary, a web of sealant can be applied to allow diffusion around the webbing. Additionally, the sealant can vary in thickness via the atomization process, where a thick enough dressing for occlusive properties is sprayed around the wound edge or dressing-to-skin interface. This application can maintain a narrow width, and then the rest of the dressing can be made into a thinner layer that is breathable based on a different number of lamination layers or by using different spraying variables and techniques. This thinner part of the dressing can maintain a continuous film embodiment with the occlusive barrier, as the debonding energy of the thinner part is significantly decreased due to the reduction in thickness, increasing the effective bond strength. Additionally, this breathable component can be webbed over the surface, instead of encompassing a continuous film embodiment.

[0119] The tube-to-dressing interface should be sealed if the connection is not prefabricated to be occlusive during its manufacturing process, as it is in the Spiracur dressing. The sealant should bond to both materials found at the tube-to-dressing interface and form an occlusive seal spanning the interface, step 1504, FIG. 33. Three methods can be used for this sealant interface and its components: 1) dressing components that were not originally prefabricated to be occlusive can be pre-assembled and sealed prior to dressing application (most desirable from an occlusive results reliability perspective); 2) dressing components can be preassembled prior to dressing application, but the seal is applied after dressing application; or 3) the tube connection method is fabricated and sealed to the dressing during or post dressing application.

[0120] The first method provides the user with a method to prefabricate a custom dressing that has an occlusive tube-to-dressing interface. This eliminates many potential air leaks, and for the first time, allows custom, prefabricated, occlusive dressings to be made in the clinical setting. Method two is convenient if the liquid sealant is the same for all dressing interfaces; therefore, all the interfaces (tube-to-dressing and dressing-to-skin) can be sealed in one step after the dressing application. However, this method requires that the pre- assembly configuration is stable during its application, before any sealant is applied. For method three, less prep-work needs to be performed by the caregiver. If this sealant method is ergonomic and repeatable without any prefabrication, then this method can significantly cut-down on dressing time, which is a significant personnel and cost savings for the care center. The ergonomic and repeatable characteristics depend on the tubing connector designs.

[0121] Multiple tubing connector designs can be manufactured for sealing purposes to be used for all three methods. Three basic design concepts can span many embodiments. These three design concepts are:

[0122] 1) Puncture the dressing with the drainage tube, such that the drape fits snuggly against the tube. Then, apply the sealant at the tube-to-dressing interface. With this method, the tube can recess into the wound cavity at a custom length as indicated by extended distal end 1801, FIG. 36. If the adhesion force of the sealant needs to be increased, an additional adhesive can be added under the sealant or mixed with the sealant, or the tubing and/or dressing can be pre-coated with a material that the sealant has an affinity for. In practice, rubberized polymers typically have a strong affinity towards themselves, even if the under layer is previously cured. Multiple drainage holes, as illustrated in FIG. 4, or a spiraled cut pattern, FIGS. 2 and 3, in the portion of the tube extending into the dressing is preferred, in order to prevent the tube from occluding against saturated packing material or with particles in the wound exudate.

[0123] 2) The same concept as in concept 1, except with a different tube entry into the dressing. This concept is for the case where an initial planar dressing is used. Two pieces of the planar dressing cover the wound from two different sides, and they meet above the wound cavity in a "T" joint. The tube is placed through this "T" joint into the wound cavity before the "T" joint is sealed. Then, all of the interfaces are sealed with the liquid sealant.

[0124] 3) The same concept as in concept 1, except at the tube-to-dressing interface, a prefabricated foot 1802, FIG. 36, also referred to herein as a flange, is attached (preferably air-tight) to the tube in order to provide a planar surface to seal to the dressing. In one functional embodiment, the foot 1802 is made of a flexible material that the sealant has a strong affinity for and no additional adhesive is necessary. The material of the foot may be tapered in thickness, such that it thins to meet at its edge(s) with the dressing, which may be more desirable for reliable, occlusive sealant application. The tube can connect to this foot 1802 in many orientations; however, it is often preferable to minimize the dressing profile. However, often when minimizing the dressing profile, the tube is in an orientation that cannot be readjusted after dressing application. Therefore, the tube may connect perpendicular to the skin surface, and by using non-kink tubing and/or the flexibility of the foot 1802 material allows the tube to be oriented in any orientation post dressing application, such that the tube will not kink and occlude itself. For this concept, the tube may not puncture the drape, but instead, the hole (a.k.a., incision) may be pre-cut; the foot should extend beyond the hole (a.k.a., incision).

[0125] 4) The fourth concept is the similar to concept 3, except the tubing does not extend into the wound cavity, FIG. 37. Therefore, an incision is made into the dressing, and the tube opening is positioned over the center of the incision, as in the T.R.A.C. Pad. The foot should extend beyond the incision and is sealed to the dressing with the liquid sealant or occlusively pre-sealed during its manufacture. In this embodiment, the end of the tube should be designed to stop potential occlusion onto the foot, onto packing materials, or with wound exudate substances. Therefore, if the foot is connected to the tube above the skin surface, the end of the tube may have a spiral cut along its length, up to its interface (intersection of the upper portion of foot 1802 and tube distal end 1901 in FIG. 37) with the foot. Additionally, an anti-occluding material may be placed at the end of the tube between the foot and the dressing. This anti-occlusive material may be a large pore, open cell sponge.

[0126] In the tube-to-dressing connection, as with all sealed interfaces, an additional adhesive may be added if the bonding strength needs to be increased. The foot may also be initially adhered with a tape or adhesive to the dressing prior to sealant application. The tube connectors can exist in many similar embodiments to those listed above; however, a limited number of examples are given here in order to illustrate the basic connections and the occlusive dressings. The tube-to-dressing interface may be occlusively pre-sealed during its manufacture. Additionally, the component attached at the interface may only consist of a tube connector (which may or may not contain a segment of tubing) that is additionally connected to a longer piece of tubing that then attaches to the pump. Examples of occlusive tube connectors are barbed connectors that connect directly with a tube, specific connectors that interlock with each other and are required on each end of the connected components, and a compression fit seal such as a cylindrical hole in rubber that the tube can be occlusively pressed into.

[0127] As previously stated, handling a dressing with a planar tape embodiment may cause the adhesive to weaken prior to dressing application. Therefore, specific handling devices for the caregiver can be included with this dressing component. These devices may include non-stick gloves, such as PTFE gloves, FIG. 24, or non-stick fingertips, FIGS. 20 and 25. Handing tabs that extend from the dressing may also be incorporated into the dressing design. These tabs may be a part of the dressing (a.k.a., drape) that are torn-off after applying the dressing, or they may be extensions of a removable backing material that is attached to the dressing as shown in FIG. 13. [0128] For application of the sealant, many application embodiments and methods are possible. For mechanical applications, including painted applications, the applicator embodiment can be a brush, roller, sponge, spatula, or other similar embodiment to apply paint in a "spreading" fashion. These spreading devices can be attached to a container (preferably refillable) of liquid sealant for a continuous feed of sealant to the applicator; this may be gravity fed (passive or user controlled), or the applicator may be prepped with sealant by dipping the applicator into a container of sealant. Although painting is not the preferred application method for the liquid dressing, it may be preferred if a high viscous sealant material is used to span large gaps, such as that between the packing material and the wound edge, the potentially high ridges of a hydrocolloid at its skin interface, or the large creases, gaps, and folds in a hydrocolloid dressing, due to its high stiffness and thickness and geometrical mismatch.

[0129] For sprayed applications, the device to atomize the sealant with a shearing process can be a refillable spray gun or airbrush, with an external pressurized gas supply, or this functionality can be incorporated into a miniature, handheld spray can, which can be rechargeable and refillable. Each embodiment has a design specific envelope of pressure, velocity and volume flow of gas that is required to shear the sealant, such that it forms a thin film, continuous layer on the skin. If the operation is outside the envelope, the droplets of the spray may be too large and will not spray as a continuous layer, but will sputter onto the skin, or the gas may not shear the fluid out of the fluid opening. In a functional embodiment, the liquid sealant is gravity fed into a center opening in a nozzle, and pressurized gas shears the sealant through a circumferential ring around the sealant nozzle opening. Multiple nozzles may exist for one or both fluids. Particularly, the spray pattern may be controlled through the shearing of the sealant from multiple gas ports, aimed in different shearing directions across the liquid sealant nozzle. In a handheld device, the pressurized gas may be generated from a miniature gas cylinder, such as a high pressure, liquid carbon dioxide cartridge. The spraying device may be charged by the caregiver when he or she activates the charged canister of gas.

[0130] Once the dressing-to-skin and tube-to-dressing interfaces are sealed (either during dressing application or during its manufacture), the caregiver should monitor the pump to assure that air is not leaking into the system above a predetermined threshold, typically zero, step 1505, FIG. 33. This can be done visually, for example, by monitoring the expansion of the pump (a.k.a., mechanical pump) or with an air leak test that is further disclosed in the pump descriptions, or it can be sensed using pressure sensors to detect the vacuum pressure over time (particularly, with a mechanical pump, if the pressure changes continuously with internal pump volume). If too high of an air leak exists, the dressing-to- skin and/or tube-to-dressing interfaces can be resealed with the liquid sealant by removing the previously applied sealant material, or overlaying the new sealant over the previously applied seal material, step 1506, FIG. 33. This is an iterative process until the desired air leak threshold is achieved, step 1507.

[0131] When a truly occlusive wound dressing is used for NPWT, the behavior of the system changes from an active flow system, FIG. 34A, to a passive flow system 1602, FIG. 34B. When air leaks, arrows 1603, FIG. 34A into the active system, the system has an active flow of fluid (both air and wound exudate) that both removes the exudate from the wound cavity 1604 and tends to dry out the wound cavity. With an air-tight system 1602, FIG. 34B, the flow of the exudate toward the pump is no longer an active flow, but tends to build up, 1605, even into the tube over time, maintaining a passive flow to the vacuum source. A pressure differential still exists at the surface of the wound bed 1606 and, thus, negative pressure is still being applied to the wound bed; however, the wound cavity volume 1604 fills with exudate fluid 1605 over time. This characteristic may have increased healing benefits compared to standard NPWT, as it maintains a moist, healing environment at the wound site, while also maintaining NPWT vacuum pressure benefits.

[0132] With this build-up of fluid 1605, FIGS. 34B and 35, the dressing-to-skin interface adhesion 1607 may be compromised over time by the exudate, and the exudate may eventually undermine the dressing and leak out of the dressing-to-skin interface. The rate of exudate removal, size of the wound cavity, and time between dressing changes determine the build-up characteristics. If there is a chance that the dressing may be compromised, it can be prevented with multiple methods, including:

[0133] 1) A sealant or additional adhesive that can withstand the exudate build-up may be applied. For this case, the sealant and/or additional adhesive should be applied as close to the wound edge as possible. This is difficult if a standard dressing was used. Planar dressings typically leak over the three-day dressing period if fluid build-up occurs. This is because the exudate often degrades the adhesive by undermining the dressing at the wound edge at the locations of initial creases in the dressing. Therefore, a dressing without initial cracks at the wound edge is preferred; however, the dressing application described in the previous section only seals the outer edge of the dressing. To solve this problem, a flexible adhesive, with flexibility and adhesive properties such as those of a 30+ day silicon wig glue, may be initially applied at the wound edge under the adhesive planar dressing. This can fill in any initial cracks at the wound edge and prevent exudate-caused degradation.

[0134] 2) A barrier can be applied at the wound edge, after the wound packing material is inserted. This barrier may be made of highly absorbent material, in order to reduce the chance of overspill of exudate due to factors, such as gravitational effects.

[0135] 3) The tube end can be recessed into the wound cavity below the plane of the surface of the skin 1702, as indicated by arrow 1701, FIG. 35. Therefore, the drainage line of fluid 1703, and hence the build-up of exudate will not build-up to the wound edge 1607, and degrade the adhesive. This technique may not be possible if the wound is superficial.

[0136] 4) A purge valve to let a controlled, temporary air leak into the dressing system to clear the fluid can be incorporated into the dressing system. This valve can be incorporated using the same connection methods as described in the Tube-to-Dressing Interface section in this disclosure. This would cause the fluid to actively flow into the fluid collection canister during the initial pressure drop in the system. The pump can be reset, if necessary.

[0137] 5) The wound packing material can be made from materials with a low resistance to the flow of exudate and a low absorption, which would encourage the fluid to passively move through the system at a faster rate in a path more direct to the drainage tube. Depending on the rate of exudate removal, this may not fix the problem if it is a very low rate. In this case, the packing material should be designed to direct flow to the drainage tube and specifically away from the wound edge.

[0138] 6) If the dressing is fabricated completely out of the liquid sealant (potentially with an additional adhesive) with no planar dressing component, then no cracks will exist at the wound edge when it is properly applied, and therefore, no cracks will initially exist for the exudate to undermine.

[0139] Although any mechanical or electrical vacuum source may be applied to the occlusive dressings in this disclosure, a mechanical system may be preferred due to the significant benefits over electrical pumps. Mechanical vacuum pumps and methods are provided for medical application in negative pressure wound therapy (PWT) that would be compatible with the disclosed dressings. A number of known pumps are described by the present inventor in "Development of a simplified Negative Pressure Wound Device" submitted in 2007 for her Master of Science in Mechanical Engineering at the Massachusetts Institute of Technology. The pump is initially set and then governed by a linear or nonlinear spring force. The pump enclosure may act as a collection chamber; however, a separate collection chamber may exist in series with the pump.

[0140] In one embodiment, the pump is a plastic bellows, shown in FIG. 31, where the enclosure and spring can be the same component. The pump is compressed manually and then attached to the tube of the wound dressing. A negative pressure is applied through expansion of the bellows due to the spring characteristics of its material and design. The pressure gradient of the device continuously decreases over the expansion of the standard bellows due to its linear spring-like properties. Referring to the above description, one skilled in the art would realize that other embodiments exist: the device could be constructed of a different material bellows, and/or the device could contain an additional spring 5 in parallel with the bellows in order to vary the spring constant without changing the material properties and design of the bellows itself. If there are no air leaks into the system, then the bellows would remain at a constant expansion length, and therefore, at a constant pressure. The bellows can be collapsed to any desired therapy pressure from maximum compression to zero.

[0141] In addition to the standard bellows, another embodiment of bellows can resemble a constant force spring, in order to decrease the pressure gradient. In one embodiment of this design, the bellows resembles a long tube that, when fully compressed, is rolled onto itself, similar to a tape measure, as shown in FIG. 32. As it unrolls and expands from its flattened to open cross-section, it creates negative pressure in the tube to which it is connected. For the tube to unroll following the expansion of the bellows, the spring constant of the bellows must be higher than the spring constant of the constant force spring unrolling. The unrolling can also be mechanically dampened, for example by adhesion, or forced to unroll after expansion by structural limiters. In this embodiment, a long, cylindrical tube can replace the bellows, as it presents similar characteristics.

[0142] In all of the pumps described above, orientation of the device is independent of the magnitude of negative pressure pulled and the proper operation of the device. Therefore, the device is highly transportable. Referring to the above descriptions, one skilled in the art would realize that other embodiments exist; however, only selected embodiments are described in detail. To change pressures in a pump design, separate pumps can be made with different material properties and/or dimensions, or components can be swapped for different pressure results.

[0143] The negative pressure generated is governed by the material and mechanical properties of the container and/or balloon and the spring constant. Using a non-constant force spring (such as a common linear spring 5, FIG. 31, the pump may be used for negative pressure wound therapy that does not require a specific, constant pressure (in the case that the internal volume of the pump is expected to expand), although the variance in pressure can be reduced through material property selection and design. Using a constant force spring with a constant area, a constant vacuum pressure can be pulled throughout treatment, even if there is a change in the internal volume of the pump. This is the basis for design of the rolling bellows (FIG. 32), and the syringe concept discussed in the next section. Additionally, a more constant pressure with pump expansion can be achieved with a non- constant force spring by designing the force/area ratio to be constant, such as the balloon design with a small (constant) diameter to length ratio and a bellows with a varying cross- sectional area. Additionally, constant pressure can be achieved over time if no air leaks into the system, causing geometrical changes in the pump configuration. In this case, the pumps should be made out of materials that do not degrade when applying negative pressure overtime due to properties such as stress relaxation.

[0144] The pump is initially set and then governed by gravity. It includes an expansion container that expands due to an applied force such as a weight. The pump enclosure may act as a collection chamber; however, a separate collection chamber may exist in series with the pump. In one embodiment, the pump includes a rolling diaphragm syringe (similar to a friction free diaphragm air cylinder). Negative pressure amplitude is governed by the diameter of the syringe and the magnitude of the attached weight. One skilled in the trade would realize that a similar device could also be constructed of any sealed piston syringe. Referring to the above descriptions, the device could also include a linear spring in parallel with the syringe or a constant force spring in series with the syringe for expansion, eliminating the need for weight. This embodiment would then fall under the spring governed pumps described in the previous section. A rolling diaphragm can also be achieved using a rubber ball design. One hemisphere of the rubber ball is held rigid in its inflated position, such as by bonding it to the inside of a rigid hemisphere, and the other hemisphere is compressed into it. The embodiment of the pump resembles a bowl. Then, the bowl is oriented so that its hollow side is facing down. A weight is hung from the ball (i.e., a rubber ball) on the hollow inside of the hemisphere, and the wound drainage tube is connected to the internal volume of the pump (preferably through the top of the rigid hemisphere). The weight pulls a negative pressure as the ball returns back to the shape of a sphere.

[0145] Another embodiment for a gravity governed pump is created by a siphon. The pump enclosure may act as a collection chamber; however, a separate collection chamber may exist in series with the pump. The pressure pulled is equal to:

rho*g*h (2)

wherein rho is the density of the fluid in the column, g being the gravitational constant, and h being the height of the column). The fluid should be compatible with the wound (such as saline), unless a check valve is used to assure separation of the pump fluid from the wound cavity. The pump can be configured in two ways, depending on the patient situation and the desired pressure:

[0146] 1. The pump can include a column of fluid that exists in a tube directly connected to the wound. The lower (preferably closed-expandable) container of fluid can rest at the desired height on a separate mechanism (such as a hanging hook or floor), or could be attached to a lower extremity of the patient, again at the desired height. The diameter of the tube would determine the pressure gradient: the larger the diameter, the lower the pressure gradient as fluid is collected.

[0147] 2. The pump can include two bodies of fluid with a tube from the higher body of fluid to the wound. The mobility of the patient would be determined by the tube length and the mechanism used to carry the pump (for instance, a rolling stand could be used). The diameter of the higher container would determine the pressure gradient: the larger the diameter, the lower the pressure gradient as fluid is collected.

[0148] Integrating the spring governed pumps with the gravity governed concept allows for further performance. Then, the magnitude of negative pressure a spring governed pump can obtain is not completely limited by the material properties of the container, the design, and the spring constant combination. Additional weights can be attached to one end of the pump in series with the spring, in order to pull a higher negative pressure. (For the bladder concept, portions of the bladder may need structural support, so mat the bladder does not collapse on itself as the weight acts on it.) The weights should be attached between the pump and ground. Even though in this form the orientation of the pump should be maintained, varying the additional weight is a simple solution to achieving multiple pressures beyond that of the original pump properties.

[0149] A container evacuation pump is not continuously governed by a force exerted on the container. Instead, the pump is simply an evacuated rigid chamber that is continuously monitored through a pressure gauge, such as gauge 4 in FIGS. 31 and 32. Alternatively, a mechanical check gauge would be used, with an optimal pressure range. When the vacuum pressure decreases to a certain, predetermined level, a notification mechanism is activated and the rigid chamber is recharged. Recharging can be by a pump or by human suction. In this embodiment, the rigid chamber can act as the collection container, or a separate non-structural, expandable container can be inserted into the rigid chamber that is directly connected to the wound drainage tube. An expandable collection chamber can be integrated into any of the mechanical pump concepts disclosed in this disclosure, in order to collect the fluid inside the pump body, acting as a collection liner instead of a completely separate collection canister.

[0150] To administer NPWT, the pump is connected to the wound drainage tube, and the container is then evacuated. Air leaks and wound drainage rate determines the pressure gradient, and the pressure range is determined by the maximum pressure pumped and the recharge notification pressure. The maximum pressure pumped can be limited by a pressure activated inlet valve.

[0151] As generally applies to all of the above-mentioned pumps, a sequence of steps should be followed. First, the tube connected directly to the dressing should be clamped shut between the dressing and the collection chamber, preferably at the collection chamber end. Then, the pump and collection chamber should be disconnected. If necessary, the collection chamber should be emptied, and/or the proper sterilization procedures should be performed; component 8, FIG. 31, represents a rubber plug, not shown because integral floor 260 is utilized instead, for increased access to the interior of the collection chamber in an alternative construction. The pump should then be reset, and the pump and collection chamber reconnected to the tube. Remove the clamp to begin NPWT again. If a dressing change is also desired, there is no need to use a clamp to keep the dressing sealed. Also, if the collection chamber does not need to be emptied and/or sterilized, then the tube should be clamped between the dressing and the pump, preferably after the collection chamber if it is separate from the pump at the pump end of the tube.

[0152] An air leak test can be incorporated into the mechanical pumps, except for the first (1) siphon concept. In the second (2) siphon concept, the higher container is turned upside-down for the initial air leak test. Most air leaks originate at the dressing interfaces. In a purely mechanical pump, air leaks fill the limited volume, causing the maximum time between pump resets to decrease. To eliminate these air leaks and create a reliable, repeatable therapy, devices according to the present disclosure may include an air leak test. By using the air leak test, the purely mechanical pumps have been proven to be capable of lasting throughout the recommended timeframe between dressing changes (3 days). However, this test is not necessary for the occlusive seals and dressings disclosed in this disclosure, but can provide a visual reassurance to the caregiver and patient that the dressing was applied properly and no significant leaks exist in the system.

[0153] The air leak test is in the collection chamber. The tube from the wound that enters into the collection chamber enters into a wound compatible solution (such as saline). When applying the NPWT, one should confirm that the end of the tube is submerged in the solution and should look at the solution for air bubbles B, FIGS. 31 and 32, (any air that initially exists in the tube may create air bubbles; therefore, one should wait about 1-2 seconds for additional air bubbles). If air bubbles are detected, the dressing should be sealed until no air bubbles are detected. This resealing may be to completely redress the wound, to smooth out the air leaks in the current dressing, or to reinforce the current dressing with additional dressing components. Once no air bubbles are detected, the pump may need to be reset depending on how much air entered into the pump.

[0154] A safety feature of the collection chamber is to limit the amount of liquid capable of being collected. If the collected liquid were blood due to destruction of a vein or artery, there exists a possibility that the patient may die due to fatal bleeding. The collection chamber should be limited to less than 300cc of liquid to keep the patient at a safe range from possible exsanguination. Therefore, if the pump design can pull more than 300cc of fluid, a safety feature should be implemented. If the pump acts as the collection chamber, the safety feature should limit its expansion volume. This can be done in various ways through the introduction of limiting, internal (FIG. 31, component 6) and/or external (FIG. 31, component 7) structural components. If an external collection chamber exists, then a safety feature should stop the negative pressure after 300cc is collected. This can be done by "plugging" the system with a mechanism, such as a float-stop valve.

[0155] Prior to the existence of a truly occlusive dressing, a benefit in the external collection chamber was that the pump can be larger than 300cc, and therefore, account for more air leaks into the system. However, with a truly occlusive dressing, the benefits include that the external collection chamber and its fluids can be easily removed for lab testing purposes, and the pump requires a less rigorous cleaning procedure between dressing changes. However, these benefits are more readily solved with a volume specific container with no rigidity, and containing no initial volume of fluid that may contaminate a exudate sample, if desired, that can be inserted into any of the mechanical pump concepts disclosed in this disclosure, in order to collect the fluid inside the pump body, acting as a collection liner instead of a completely separate collection canister. The 300cc limitation is recommended for the average adult; however, the limitation volume may vary based on the patient. This volume variation can be designed into multiple pump or collection chamber sizes, or into a single, limit adjustable pump or collection chamber.

[0156] Another pump safety feature is a one-way valve incorporated in the tube between the wound and the collection chamber, such as component 2, FIGS. 31 and 32. This mechanism assures that fluid from the pump and collection chamber does not flow back into the dressing. It also can be used as the tube clamping mechanism for resetting the pump or emptying the collection chamber, depending on placement in the tube. This mechanism can also be incorporated into the tube connector on the collection chamber.

[0157] Another mechanism that may be included is used to evacuate the initial air found in the system after no air leaks are detected. The current method is to clamp the tube near the pump and to reset the pump until the initial air is evacuated from the system. This can also be accomplished by including a one-way- valve incorporated into the tube connector on the pump, such as component 2, FIGS. 31 and 32, and another one-way-valve incorporated between the interior cavity of the pump and atmosphere, component 3, shown with a cap C in FIG. 31. With this design, one can continue to compress (reset) the pump until the desired vacuum is maintained; the system does not need to be disconnected. The one-way-valve open to atmosphere can be capped after therapy begins.

[0158] This mechanism cannot be easily integrated to eliminate the need for resetting the pump in the design that includes a rubber balloon that is inserted into an orifice of an air-tight container and the two siphon pumps. For the balloon design, a connection to the container can be made to incorporate the attachment of a separate pump with the oneway-valve and check valve design. This pump can be attached for initial balloon inflation and container evacuation, and then detached between dressing changes. In the two siphon concepts, a pump can be attached to evacuate the space above the column of fluid, raising the fluid level to the desired height. The pump can be detached for extended therapy, between dressing changes.

[0159] An individual sealant component may be packaged by itself to make any skin dressing occlusive. Alternatively, the sealant can be packaged as part of a mechanical NPWT kit, including a mechanical pump and its pre-attached components, tubing with flexible foot and pre-attached tubing connector and optional one way valve, dressing adhesive film to cover the packing material (if necessary), the sealant material in a handheld spray container, a wound packing material, and skin prep (if necessary). Additionally, if there is an adhesive dressing tape-like film that should be handled by the caregiver, then non-stick fingertip covers maybe included for better adhesion outcomes. Non-powdered gloves may also be included, so that the Van der Waals forces for sealant attachment are not altered due to powder on the skin surface. One skilled in the art would realize that kit components may be swapped for their different functional embodiments, discussed above. Also, additional components may be added or put into additional kits that are used in typical dressing changes, such as wound debridement tools, or additional wound therapies, such as medications with their corresponding introduction and (potentially) removal ports through the dressing, into the wound cavity.

[0160] As many dressing systems are identified in this disclosure, one skilled in the art would realize that the liquid sealing method can be used in combination with any tissue (a.k.a., skin) dressing in order to create an air-tight seal. As many pumps are identified in this disclosure, one skilled in the art would realize that any pump combined with the occlusive dressing systems would have similar performance characteristics.

[0161] One technique according to the present invention for constructing an occlusive dressing over a wound includes at least one of (1) packing the wound with a fluid- pervious material and (2) covering at least a portion of the wound with a protective material. The method further includes applying, such as by spraying, an organic material, preferably elastomeric, that is in a liquid state, and is at least partially cross-linked at least after one of drying and curing, over the packed material and onto skin surrounding the wound to create an occlusive drape as a thin sheet substantially impervious to fluid transfer, having a first, inner surface and a second, outer surface. As utilized herein, the term "organic material" includes matter in various forms that include carbon atoms, including silicone rubbers. The method includes at least one of drying and curing the elastomeric material within thirty minutes after application of the elastomeric material as a layer.

[0162] FIG. 38 is a schematic top plan view of the wound shown in FIG. 14, here with a cleaned skin zone indicated by dashed line 302 and with packing material 304, such as gauze or a sponge. Additionally, a protective covering material 306 is applied over the wound when intended liquid drape material has a sufficiently lower viscosity and longer set time to be absorbed into the packing material 304. Protective material 306 prevents liquid drape material from flowing into the wound cavity. In some constructions, protective material 306 is a solid impermeable or semi-permeable polymeric sheet, which may be utilized with or without adhesive. In other constructions, protective material 306 is a claylike substance that can be molded and packed over packing material 304 and around a tube inserted into the packing material 304.

[0163] FIG. 39 is a view of FIG. 38 with a hole 308 cut in the protective covering 306, if an opening in the protective covering 306 has not already been formed or maintained.

[0164] FIG. 40 is a view of FIG. 39 with a tube assembly 27c, with tube 24c and flange 26c, having sleeve 52d, rotation region 54d and adhesion region 56d, placed over the hole 308. Tube assembly 27c is maintained in position with adhesive in some techniques and, in other techniques, is manually held in place. Alternatively, tube 24c can directly puncture protective covering 306 such that covering 306 maintains a tight seal around tube 24c, potentially with an additional seal barrier such as clay or adhesive. In another construction, flange 26c is sufficiently large in diameter to completely cover the wound.

[0165] FIG. 41 is a view of FIG. 40 with liquid drape material 310 applied over the protective covering 306 and onto surrounding skin SK to cover skin zone 302 to thereby construct a dressing according to the present invention. The liquid drape material 310 is applied by spraying or application technique such that material 310 firmly attaches to skin SK surrounding the wound and covers any protective cover layer 306, if utilized, as well as creating an air-tight seal around flange 26d. FIG. 42 is a schematic perspective view of the dressing of FIG. 41 In other constructions, the drape is constructed directly onto a tube without utilizing a separate flange.

[0166] FIG. 43 is a schematic perspective view of a novel flange 26d according to the present invention with integral connector 320 having a barb-type engagement feature 322 defining passage 324. Engagement feature 322 is insertable into end of a tube.

[0167] Although specific features of the present invention are shown in some drawings and not in others, this is for convenience only, as each feature may be combined with any or all of the other features in accordance with the invention. While there have been shown, described, and pointed out fundamental novel features of the invention as applied to one or more preferred embodiments thereof, it will be understood that various omissions, substitutions, and changes in the form and details of the devices illustrated, and in their operation, may be made by those skilled in the art without departing from the spirit and scope of the invention. For example, it is expressly intended that all combinations of those elements and/or steps that perform substantially the same function, in substantially the same way, to achieve the same results be within the scope of the invention. Substitutions of elements from one described embodiment to another are also fully intended and contemplated. It is also to be understood that the drawings are not necessarily drawn to scale, but that they are merely conceptual in nature. It is the intention, therefore, to be limited only as indicated by the scope of the claims appended hereto. Other embodiments will occur to those skilled in the art and are within the following claims.

Negative-pressure wound therapy

Application of a vacuum pump using a foam dressing to a wound

Negative-pressure wound therapy (NPWT) is a therapeutic technique using a vacuum dressing to promote healing in acute or chronic wounds and enhance healing of first and second degree burns. The therapy involves the controlled application of sub-atmospheric pressure to the local wound environment,[1] using a sealed wound dressing connected to a vacuum pump.[2][3] The use of this technique in wound management increased dramatically over the 1990s and 2000s[4] and a large number of studies have been published examining NPWT.[5] NPWT appears to be useful for diabetic ulcers[6] and management of the open abdomen (laparotomy) [7] but further research is required for other wound types.[8]

Overview

NPWT promotes wound healing by applying a vacuum through a special sealed dressing. The continued vacuum draws out fluid from the wound and increases blood flow to the area.[2] The vacuum may be applied continuously or intermittently, depending on the type of wound being treated and the clinical objectives. Typically, the dressing is changed two to three times per week.[3] The dressings used for the technique include open-cell foam dressings and gauze, sealed with an occlusive dressing intended to contain the vacuum at the wound site.[1] Where NPWT devices allow delivery of fluids, such as saline or antibiotics to irrigate the wound,[9][10] intermittent removal of used fluid supports the cleaning and drainage of the wound bed.[11]

In 1995, Kinetic Concepts was the first company to have a NPWT product cleared by the US Food and Drug Administration.[12] Following increased use of the technique by hospitals in the US, the procedure was approved for reimbursement by the Centers for Medicare and Medicaid Services in 2001.[1]

Technique

General technique for NPWT is as follows: a dressing or filler material is fitted to the contours of a wound (which is covered with a non-adherent dressing film) and the overlying foam is then sealed with a transparent film. A drainage tube is connected to the dressing through an opening of the transparent film. A vacuum tube is connected through an opening in the film drape to a canister on the side of a vacuum pump.[13] or vacuum source, turning an open wound into a controlled, closed wound[2] while removing excess fluid from the wound bed to enhance circulation and remove wound fluids. This creates a moist healing environment and reduces edema.[5][13] The technique is usually used with chronic wounds or wounds that are expected to present difficulties while healing (such as those associated with diabetes).[3]

Three types of filler material are used over the wound surface: open-cell foam, gauze and transparent film, or honeycombed textiles with a dimpled wound contact surface.

Foam dressings are used to fill open cavity wounds and can be cut to size to fit wounds. The foam dressing is applied, filling the wound and then a film drape is applied over the top to create a seal around the dressing.

Open weave cotton gauze can be covered with a transparent film, and a flat drain is sandwiched in gauze and placed onto the wound. The film drape covers the wound and create a complete seal, and then the drain is connected to the pump via the tubing.[14]

Layers of non-woven polyester, joined by a silicone elastomer, has a non-adherent wound contact surface made up of numerous small semi-rigid dome structures,[15] though this solution has not completed a clinical trial as of December 2012.[16]

With all three techniques, once the dressing is sealed the vacuum pump can be set to deliver continuous or intermittent pressures, with levels of pressure depending on the device used,[13][14][17] varying between −125 and −75 mmHg depending on the material used and patient tolerance.[15][18] Pressure can be applied constantly or intermittently.[13]

The dressing type used depends on the type of wound, clinical objectives and patient. For pain sensitive patients with shallow or irregular wounds, wounds with undermining or explored tracts or tunnels, gauze may be used, while foam may be cut easily to fit a patient’s wound that has a regular contour and perform better when aggressive granulation formation and wound contraction is the desired goal.[19]
Effectiveness

A 2007 Cochrane Review stated that the evidence comparing NPWT to alternative care was flawed and required more study, but the evidence did support improved healing and called for more, better quality research to be conducted.[8] A 2010 systematic review found "consistent evidence of the benefit of NPWT" in the treatment of diabetic ulcers of the feet. Results for bedsores was "conflicting" and research on "mixed wounds" was of poor quality, but promising. The review did not find evidence of increased significant complications. The review concluded "There is now sufficient evidence to show that NPWT is safe, and will accelerate healing, to justify its use in the treatment of diabetes-associated chronic leg wounds. There is also evidence, though of poor quality, to suggest that healing of other wounds may also be accelerated."[6]

Negative pressure wound therapy: Use with care

By Nasrin Mirsaidi, MSN, RN, CNOR

NEGATIVE Pressure wound therapy (NPWT) is used to treat acute and chronic wounds. A vacuum source creates continuous or intermittent negative pressure inside the wound to remove fluid, exudates, and infectious materials to prepare the wound for healing and closure.[1] NPWT systems consist of a vacuum pump, drainage tubing, a foam or gauze wound dressing, and an adhesive film dressing that covers and seals the wound.

Since 1997, when the first device indicated for NPWT was cleared by the FDA for marketing in the United States, the system has evolved considerably. New device and dressing features have been added that make the system safer, more efficient, and more user-friendly in care settings other than hospitals, such as in long-term care facilities, rehab centers, and even patients' homes.

Although many patients have benefited from NPWT, adverse events – including deaths and serious injuries – have been reported to the FDA. The following is a case example:

An older adult underwent bilateral femoral endarterectomy for severe peripheral arterial disease. About 1 week after the procedure, the patient required surgery for wound exploration and evacuation of blood clots and then was diagnosed with an infection of the right groin incision. An NPWT system was applied to the wound and the patient was discharged home on antibiotic and coagulation therapy.

Ten days later, the patient experienced a massive hemorrhage from the right groin wound. When paramedics arrived at the home, they provided basic life and advanced cardiovascular life support. After transport to the ED, the patient was pronounced dead. The cause of death was exsanguination.

What went wrong?

The most serious adverse events associated with NPWT, blood loss and infection, can be prevented if healthcare professionals pay close attention to:

Device labeling, including warnings, instructions for use, indications, and contraindications.

Criteria for patient selection, wound type, and appropriate care setting based on each patient's needs.

What precautions can you take?

These strategies are recommended to prevent complications:

Patient selection and wound type.

Patients should be thoroughly evaluated for bleeding risk. The patient in the case example had several risk factors for bleeding, including history of postoperative blood clots in the wound, anticoagulation therapy, and wound infection. Besides being at high risk for infection, groin wounds are also prone to delayed wound closure due to hip joint movement.

High-risk patients and selection of care setting.

NPWT should be used in an appropriate healthcare setting based on the patient's need for monitoring and wound care. At high risk for bleeding and infection, this patient should have been in a healthcare facility where healthcare professionals are available around the clock.

Wound care-specific considerations.

Many reported adverse events are the result of inappropriate methods of dressing change. For instance, bleeding can occur from improper removal of dressings that have adhered to or are imbedded in the tissues. Bleeding can also occur if the dressing is applied directly to exposed or superficial vessels in or around the wound that haven't been completely covered and protected as recommended by the device manufacturer before initiating NPWT.

Wound infections may develop if pieces of dressing are retained in the wound. To prevent this complication, device instructions recommend counting the total number of dressing pieces used in the wound and documenting that number on the outer adhesive film dressing and in the patient's medical record. Teach the caregiver to count the number of dressing pieces removed to make sure that all pieces are accounted for.

Training of healthcare providers, patients, and caregivers.

Healthcare providers using NPWT devices should undergo appropriate training on device use, including its indications and contraindications, and recognition and management of potential complications.

NPWT training for patients and their caregivers who will be using the device at home should include how to:

Safely operate the device; provide a copy of printed instructions for patient use from the specific device manufacturer

Respond to audio and visual alarms

Perform dressing changes

Recognize signs and symptoms of complications, such as redness, warmth, and pain associated with possible infection

Contact appropriate healthcare providers, especially in emergency situations

Respond to emergency situations; for instance, if bright red blood is seen in the tubing or canister, to immediately stop NPWT, apply direct manual pressure to the dressing, and activate emergency medical services.

Use return demonstrations to evaluate patients' and caregivers' skills and comprehension of training materials.

On November 13, 2009, the FDA published a preliminary public health notification on the use of NPWT systems. It will be updated according to findings of an ongoing investigation. Please review the links below for further details. You play an important role in keeping your patients safe when using NPWT.

The clinical effectiveness of negative pressure wound therapy: a systematic review

X. Xie, M. McGregor, N. Dendukuri

Objective: To estimate the efficacy of negative pressure wound therapy (NPWT), on the basis of a systematic review of reported randomised controlled trials (RCTs).

Method: A systematic literature search for relevant RCTs was carried out. The credibility of the outcome of each study was evaluated using a specially constructed instrument.

Results: We identified 17 RCTs, of which five had not been included in previous reviews or health technology assessments. For diabetic foot ulcers (seven RCTs), there was consistent evidence of the benefit of NPWT compared with control treatments. For pressure ulcers (three RCTs), results were conflicting. In trials involving mixed wounds (five RCTs), evidence was encouraging but of inadequate quality. Significant complications were not increased.

Conclusion: There is now sufficient evidence to show that NPWT is safe, and will accelerate healing, to justify its use in the treatment of diabetes-associated chronic leg wounds. There is also evidence, though of poor quality, to suggest that healing of other wounds may also be accelerated.

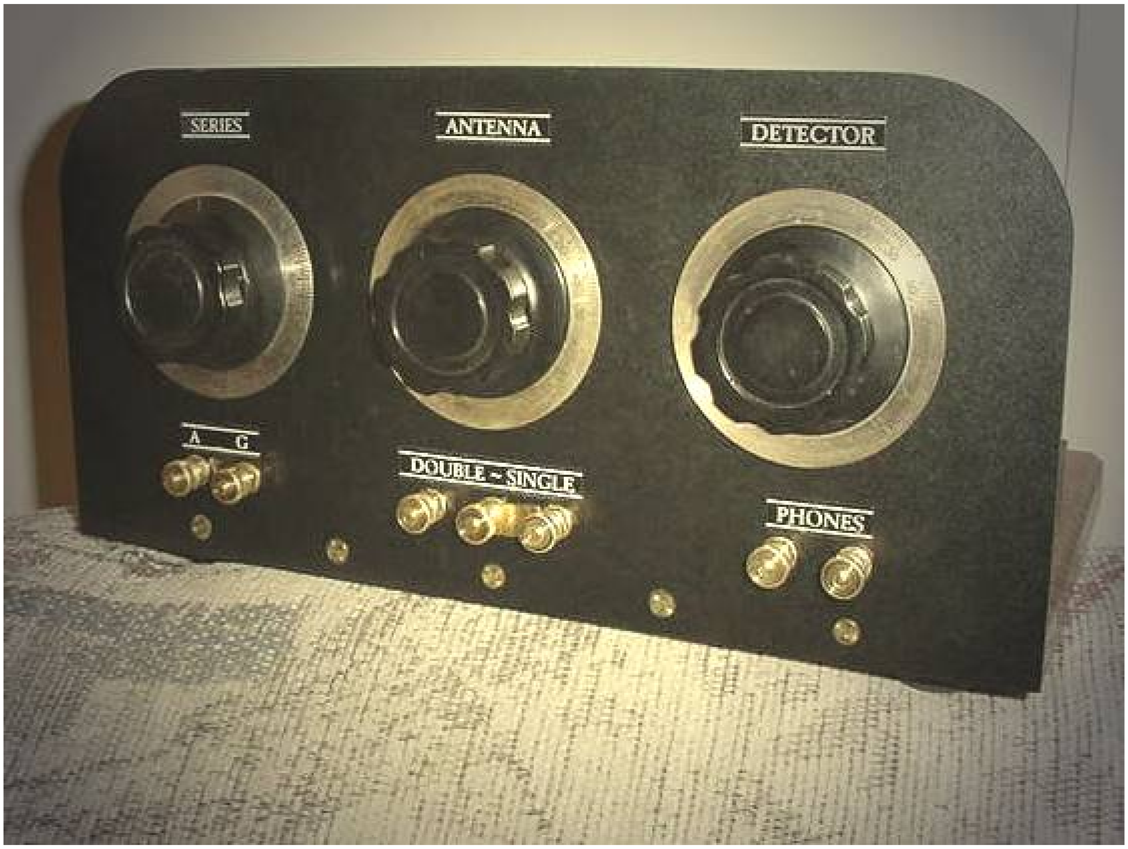
Dave's Homemade Radios

The sweetest music comes from a radio you made!

Two Radios in one — My #24 Crystal Radio



A- (javascript:changeFontSize(-1)) A+ (javascript:changeFontSize(1)) (javascript:changeFontSize(1))

Hi there! This is another of my recently revised radios. Not that I built them wrong to begin with, but I come across new and better materials to make my sets. I don't mind going back and revisiting a set now and again.

Building on the success of my last (23.php) radio, I proudly offer this crystal set for consideration for your next construction project. This is another one of my dual circuit crystal radios. The idea for this set comes from Mike Tuggle's Lyonodyne 17 (http://www.crystalradio.net/crystalsets/lyonodyne/index.shtml) and experience that I have gotten from my past sets. I found that with a very simple switching system, I can make this radio's circuit act like two different ones. I have wanted to build a Lyonodyne type set for a while but couldn't resist adding the extra switch.

This radio features the use of three variable capacitors. While at first, this is quite a chore to tune, after a while you would get used to where the dial is to be set for certain stations. You also have a choice of two radio circuits in one radio. One is the single coil that works very well and is featured in my #12 (12.php) and other sets. A hidden feature of this radio circuit is that the unused coil / capacitor becomes a wave trap! This wave trap can be used to reduce the signal of a loud interfering blowtorch station, allowing you to hear other, weaker stations that are close in frequency.

The two coil receiver is similar to the Lyonodyne circuit. The series tuning capacitor has been transposed so it is in the antenna line, rather than the ground line. I also decided to use two capacitors, rather than one capacitor. This increases the tuning complexity of this radio. The circuit was explained in some forums, but I just couldn't wrap my arms around using one ganged capacitor, so I used two. Since this is my radio, I built it my own way. It is kind of a "German" in me.

The antenna coil is the original one I used in this set. I could have used 660/46 litz on both coils, but this works dandy the way it is. The best inductance in the antenna coil will depend on your antenna. It is cut and try but you have leeway. My antenna is a single wire about 75 feet long.

The detector coil is made from 660 strand 46 gauge litz wire. This is the first coil I wound with the big litz. It came up short from the 240 µH that I wanted for my other project but will work pretty well in my single / double coil arrangement. The worst case is that the low end of the band can't be tuned without an extra capacitor.

The coils are mounted using dowel rods and 1/2 inch square wood blocks. I have used this scheme in my #23 (23.php) and #16 (16.php) sets with good results. I made it so the antenna coil could slide to adjust the amount of coupling used. Most of the time I use them fully apart for the best selectivity. If you experience real weak reception, you can move the coils closer together.

My revision included changing the detector circuit to match the extra high performance of the detector coil. This included using the 100k to 1.5k ohm audio transformer. You can pick out the transformer that meets your headphones requirements, or build a matching box (../misc-stuff/transformer.php) . The coil and the transformer turn this set into a high performance radio. If you can, try to find good quality variable capacitors. The ones commonly available really aren't that good in high performance radios. The capacitors I selected have a ceramic insulation on the stator.

The circuit details is where it starts to get interesting. Look at the circuit below while I rattle on about this set. When the switch is set to double, you see an antenna input, series capacitor connecting to a coil / capacitor parallel circuit. If you set the switch to single, you see an antenna input, series capacitor also connecting to a coil / capacitor parallel circuit. In the case of the double switch position, there are two tuned circuits, compared to a single tuned circuit in the single position. I just found that highly interesting and also helped me in how I should tune this set.

Here is how I tune this radio. There are three variable capacitors, the **series** (in series with the antenna), the **antenna** tuning (across the antenna coil) and the **detector** tuning (across the tapped coil). Tuning to maximum means that the capacitor plates are fully meshed and minimum means the plates are open. Ok? Here we go.

Single position tuning instructions: Tuning starts at the high end of the band and works downwards. Set the detector and series capacitors fully open. Fully mesh the antenna tune capacitor (if you are near the low end of the band, this capacitor should be fully open as it is a wave trap). Rotate the series capacitor as you listen for stations. If you hear a strong station, and want to increase the selectivity (at the cost of some sensitivity), mesh the plates of the detector capacitor a little and then peak the series capacitor to maximize the signal. After you make your first pass, set the detector capacitor at a third of rotation and start tuning again. Do this until you have reached the bottom of the band. The antenna capacitor can be tuned to tune out a loud station so you can hear others. Try it.

Double position tuning instructions: Tuning is a lot like in the single position. Set the antenna capacitor at minimum. Rotate the detector capacitor a little at a time while sweeping the series capacitor. You will be tuning starting at the high end of the band. When you hear a signal, then start peaking each capacitor starting with the antenna, then detector, then back to series. Keep repeating that until the signal is at full strength. Having numbered knobs and keeping a log of the settings helps finding the station again.

As a little "extra", I have included a little circuit to use if your sets don't tune the full range. It is a padder arrangement. Instead of hooking two gangs of a capacitor together for full range tuning, adding a padder capacitor will allow you to tune only to the bottom of the band. That way, you can spread out your tuning range to fit the full rotation of the capacitor. It does require the use of a 2 gang capacitor.

I haven't talked too much about construction details on this page. I have a new construction hints (../misc-stuff/cp.php) page on my site. Also, take a look back through my previous sets for little nuggets of hints. If you have a question or two, or would like to chat about crystal sets, I am only an e-mail away.

Best wishes and good DX. Dave - N2DS

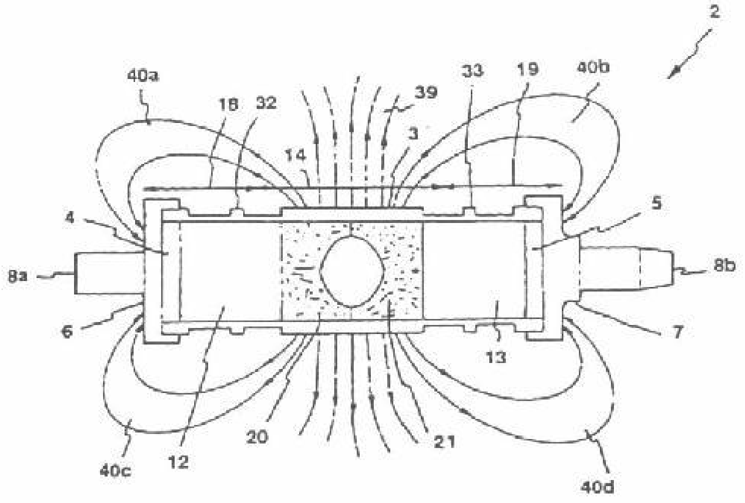
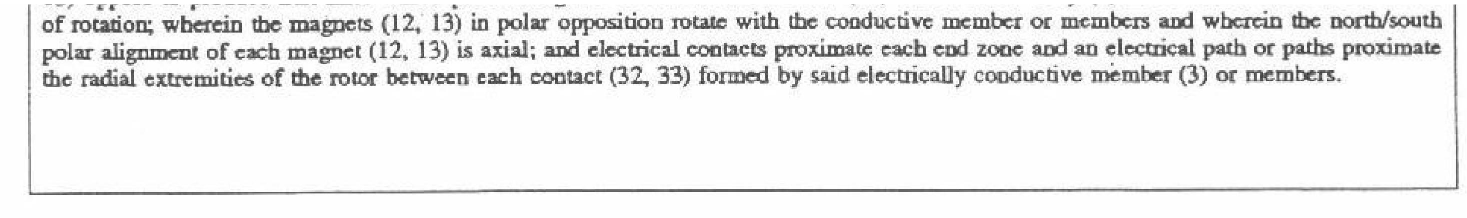
(54) **Title:** A HOMOPOLAR GENERATOR



(57) **Abstract**

A single piece homopolar generator (1) for use alone or in combination with a like or known generators comprising: current collectors co-operating with a rotor body (2) wherein the rotor body (2) comprises: at least one electrically conductive member (3), a central zone (14) between the zones (18, 19), at least two actually aligned magnets (12, 13), arranged so that the poles (20, 21) of the magnets (12, 13) oppose to produce flux lines which pass through and exit the central zone (14) of said rotor body (2) in a direction radial to the axis



of rotation; wherein the magnets (12, 13) in polar opposition rotate with the conductive member or members and wherein the north/south polar alignment of each magnet (12, 13) is axial; and electrical contacts proximate each end zone and an electrical path or paths proximate the radial extremities of the rotor between each contact (32, 33) formed by said electrically conductive member (3) or members.

A HOMOPOLAR GENERATOR

BACKGROUND

[5] The present invention relates to an electric generator. The generator described herein is referred to as a quadrapole generator because of the four distinct magnetic poles involved in the machine.

PRIOR ART

[10] In 1831 Michael Faraday performed the initial experiments which resulted in the discovery of the dynamo. In one of his experiments a copper disc was secured to a cylindrical magnet with paper intervening the two. The poles of the magnet were aligned along the axis of the copper disc. Wires of a galvanometer brushed the centre and circumference of the copper
[15] disc respectively. It was discovered that upon rotation of the copper disc and magnet, an electrical potential was created between the terminals of the galvanometer. This simple construction is known as a homopolar generator. Importantly, this experiment revealed that a potential difference was created across the copper disc when it was rotated through a magnetic field, irrespective of whether the magnet was rotated with the copper disc or[20] remained stationary.

Another early generator was the two piece design by Faraday where a conducting disc is revolved adjacent to the poles of fixed magnets.

[25] Homopolar generators produce low voltages at high currents. In the later 1800's these unipolar generators were used in metal reduction and plating applications where high currents are required. In the early 1900's however, the development of commutated DC and AC generators which could develop higher voltages at lower operating speeds led to the decline in use of homopolar generators, except for specialised applications.

[30]Another prior art generator involves the combination of two one piece homopolar generators similar to that designed by Michael Faraday in 183 1 and mounted in common on a central supporting conducting shaft. This generator was constructed with magnet poles aligned in opposition so that they were voltage additive between two current collector rings encircling
[5] the centers of the tandem rotating magnets. The current generated by this generator flows radially inward in a conducting disc located centrally within and co-axially disposed within one magnet through the connecting axle and then radially outward in a disc co-axially disposed within the second magnet. The mechanism of voltage generation in this generator was similar to that in the previously described one piece Faraday homopolar generator[10] wherein the magnetic flux lines within the magnets are perpendicular to the conducting disc co-rotating with and centrally disposed within each permanent magnet assembly.

One disadvantage of this generator is that the current output is limited by the diameter of the supporting axle. If the axle is larger, it is necessary to have larger holes in the magnets [15] through which reverse flux may pass. The necessity for the hole through the magnets and the reverse flux problem reduces magnet strength and voltage.

The copper discs of this generator were subdivided into two spirals to produce a self magnetising effect with current withdrawal which counteracted partially the high internal [20] resistance ofthe long current path through the two copper spirals and the axle. The 50mm diameter shaft limited current output to four kiloamperes. Above this current level excessive heating would occur.

Another disadvantage of this prior art generator is that the dumb-bell shaped rotor lacks[25] rigidity compared with the rotor of the present invention to be described below. This affects ease of balancing the rotor.

DESCRIPTION OF INVENTION

According to the present invention there is provided a single piece homopolar generator which has one moving part, the rotor and in which the desired electrical potential is produced

[5] without the mutual interaction of a second member (stator). This generator includes an electrically conductive member such as a cylindrical tube having two magnets therein which) when the generator is in operation, rotate with the tube. The cylindrical version of this generator, known as a Quadrapole, is not an immediately apparent development of the original Faraday 'one-piece' axially rotated magnet experiment since the vector directions of

[10] the (radial) magnetic flux lines and axially flowing electrical current are interchanged in their respective directions in comparison to the previously described Faraday Disc experiment.

The one-piece, rotor only version of what is presently known as a cylindrical homopolar generator has not hitherto previously been known.

[15]

Throughout the specification the term 'homopolar' can be taken to mean the repulsion of like magnetic fields, i.e. N-N or S-S which can alter the direction of magnetic flux lines and produce a radial pattern in the central zone of the rotor.

[20] Within the last ten years certain materials such as rare earth, Neodymium-Iron-Boron $Nd_2Fe_{14}B$), and Samarium-Cobalt (SaCo) permanent magnets, and Niobium-Tin or Niobium-Titanium superconductive magnet wire have become available. With these materials it becomes practical to fabricate magnetic structures impossible to realise with iron and copper wire. The configuration of the present invention exploits the advantages thatmodern magnetic materials provide[25].

It is an object of the present invention to provide an improved generator or to at least provide the public with a useflil choice.

[30] In one broad form of the invention there is provided an electric generator comprising:

a single piece homopolar generator for use alone or in combination with like or known generators comprising:

> current collectors co-operating with a rotor body wherein the rotor body comprises; at least one electrically conductive member,
>
> [5] a central zone between end zones,
>
> at least~two axially aligned magnets, arranged so that like poles of the magnets oppose to produce flux lines which pass through and exit the central zone of said rotor body in a direction radial to the axis of rotation;
>
> wherein the magnets in polar opposition rotate with the conductive member or members and[10] wherein the north/south polar alignment of each magnet is axial; and electrical contacts proximate each end zone and an electrical path or paths proximate the radial extremities of the rotor and between each contact formed by said electrically conductive member or members.

[15] Preferably there is one electrically conductive member comprising a cylindrical tube and the magnets are permanent magnets which are permanently fixed with respect to the tube. The poles of the magnets are preferably orientated co-axially with the axis of the tube and the tube is preferably rotated at high speed.

[20] Alternatively, the pefformance characteristics of the generator may be achieved by use of alternative structural arrangements which receive and retain the magnets and other rotor components. For example, it would be possible to use an array of radially disposed conductors such as rods providing electrical paths connecting electrical contacts on the rotor Alternatively, the generator may comprise concentric cylinders or a nest of cylindrical tubes [25] whose axes are parallel.

According to another embodiment there is provided an electnc generator as hereinbefore described including an electrically conductive compensation tube provided about said central zone and spaced apart therefrom, an end of said compensation tube being electrically connected to the contact adjacent thereto, the other end of said compensation tube being electrically connected to a generator output terminal.

The advantages of the homopolar generator according to the present invention include the [5] following:

> a solid magnet across the frill internal diameter of the tube providing higher and uniform magnetic field and the elimination of current flow through the magnet and an increased current carrying capacity now only limited by the size of the current collectors.

[10] In another broad form the present invention comprises;

> a rotor for use with a generator as hereinbefore described, the rotor comprising; a rotor body comprising;
>
> at least one electrically conductive member, a central zone between end zones,
>
> [15] at least two axially aligned magnets arranged so that like poles of the magnets oppose to produce flux lines which when the rotor is in use pass through and exit the central zone of said rotor body in a direction radial to the axis of rotation;
>
> wherein the magnets in polar opposition rotate with the conductive member or members and wherein the north/south polar in alignment of each magnet is axial; and
>
> [20] electrical contacts proximate each end zone and an electrical path or paths proximate the radial extremities of the rotor between each contact formed by said electrically conductive member or members.

In an alternative form, the invention comprises;

> [25] a current collector for use with a generator as hereinbefore described, the current collector comprising;

a two part body one of which pans is detachably attached to the other part, wherein when the two parts are attached, a central bore is formed which receives a rotor,

means located at least partially within said bore for creating a seal between the rotor and the [30] outside of the bore, wherein said means forms a circumferential recess within the bore in which an electrically conductive material is located and which is in electrical contact with electrical contacts on a rotor in the generator, wherein, the space between the base of the recess and the electrical contacts of rotor is filled with liquid metal or eutectics providing an electrical path between the rotor and the current collector.

[5] Preferably the electrical contacts are machined into the rotor and comprise a circumferential nng on each end zone, providing an electrical connection between the surface of the cylindrical tube and the conductive liquid metal or eutectics.

[10] In a flinher form according to the system aspect the present invention comprises:

a system for generating electricity using a single piece homopolar generator; the system comprising;

the single piece generator, having one moving part, the rotor, and in which the desired electrical potential is produced without mutual interaction of a stator,

[15] a power source to drive the generator,

a field of energy influence within which the generator is situated and with which the generator interacts,

wherein the interaction between the generator and the field influences the output of the generator by supplementing energy input to the generator from said power source.

[20] A rotor may be constructed of multiple concentric conducting cylinders. In the zone of zero or low magnetic flux pertaining to the region encircling the centers of rare-earth magnets or super-conducting solenoids, muitiple sliding liquid metal contacts may be established thus enabling a series connection of the portions of the concentric conducting cylinders in the [25] voltage generating region between the opposing poles of the rotating magnets contained within the nested cylinders. Voltage addition by connecting a series of concentric conducting cylinders in a one-piece cylindrical homopolar generator has not previously been known.

Because of the existence of a region of zero radial magnetic field in a zone encircling the [30] center of a cylindrical permanent magnet, i.e. the neutral zone, current extraction from the rotating member is taken at this point. Current extraction by means of a liquid metal sliding contact in this zone eliminates any electro-magnetic forces which might act to disturb the liquid metal contact during current extraction. A zone of zero magnetic flux also eliminates electrical currents circulating transversely through the conductive body of a current collector [5] because of inhomogeneities in voltage across the width of the liquid metal sliding contact.

With the Quadrapole, the magnets are arranged NSSN or SNNS and the fact that the magnetic flux lines emerge radially from the center of the conducting cylinder is because of the mutual repulsion of opposing directions of like (homopolar) force.

[10] In the conventional two-piece cylindrical homopolar machine, magnetic flux lines are caused to emerge radially from the central voltage generation segment of the cylindrical rotating member by fixed iron pole pieces which encircle the rotating cylinder and form part of a stator structure which closes the magnetic flux paths in fixed external loops back to each axle [15] of the machine. The two piece closed path construction makes no use of the mutually repulsive effect of homopolar magnetic fields because in the closed path construction the magnetic field internal to the cylinder is directed to flow radially outward by low magnetic reluctance external pole pieces.

[20] Without the provision of external pole pieces and a closed magnetic flux path, the attainable magnetic field strength within such a machine would be so low as to render the machine not suitable for commercial application. Rare earth high strength permanent magnets make it possible to obtain high strength and usefiil radially directed magnetic flux lines without closed magnetic flux paths. The radially directed flux arises from mutual repulsion of homopolar [25] fluxfields.

The key requirements of the cylindrical one-piece homopolar generator as herein described are that all parts of the rotor including the magnets must rotate together and there is no closure of the magnetic flux paths by fixed ferromagnetic yokes, - stators.

[30] If the permanent rare-earth magnets are replaced with super-conducting electrical solenoidal coils, the coils must rotate with the cylinder. The magnetic fields produced when they are cooled and energised must be poled NSSN or SNNS and the spacing of the coils adjusted to produce radial flux lines perpendicular to the central voltage producing segment, (of the [5] rotating conductive cylinder enclosing and supporting the magnet solenoids). The mutual repulsion of homopolar flux fields is employed to create radially diverging flux lines in the central zone

The present invention in all its forms will now be described in more detail according to a [10] preferred but non-limiting embodiment and with reference to the accompanying illustrations wherein:

Figure 1: shows a long sectional view through a generator rotor according to a preferred embodiment;

Figure 2: [15] shows an exploded view of the generator incorporating the rotor of figure 1 according to a preferred embodiment of the invention;

Figure 3: shows an isometric exploded view of one current collector for use with the generator;

Figure 4: shows an assembled view of the current collector of figure 3,

Figure 5: [20] shows the rotor of figure 1 seated in part of current collectors and showing the relationship of the rotor to the electrical contacts and seals.

Figure 6: shows a long section through the generator rotor of figure ~ with lines of magnetic flux indicated,

Figure 7: shows an embodiment of the rotor according to a preferred embodiment of [25] the present invention including magnetic compensation,

Figure 8. shows an isometric view of the completed generator with output terminals according to a preferred embodiment of the invention, and

Figure 9: shows the generator of figure 8 from a rear view driven via a drive belt by a drive motor.

Referring now to figure 1 there is shown a sectional view ofa rotor 2 for use with a generator I (see figure 2) according to a preferred embodiment of the invention. Rotor 2 comprises an electrically conductive cylindrical tube 3 which may include end plates 4 and 5. End plates 4 and 5 each preferably comprise an aluminium disc. Fixed to the ends of [5] cylindrical tube 3 and covering plates 4 and 5 respectively are non magnetic stainless steel end caps 6 and 7. End caps 6 and 7 terminate in shaft ends Ba and Sb respectively. End caps 6 and 7 are preferably affixed to the cylindrical tube 3 by means of screw threads 6a and 7a located on end caps 6 and 7 respectively. Alternatively, end caps 6 and 7 may be fixed via an internal thread (not shown) on inner surface 3a of cylindrical housing 3 or fixed with a glue [10] or friction fitted. The electrically conductive tube 3 of rotor 2 may comprise as an alternative hollow members such as but not limited to a sphere or cube. Shaft ends Ba and Sb may be integral with or are detachably connected to end caps 6 and 7 and are co-axial with cylindrical tube 3. Rotor shaft ends Ba and Sb are, when in situ, surrounded by bearing assemblies 9a and 9b (see figure 2) respectively allowing free rotation of the cylindrical tube [15] 3 upon rotation of rotor shaft B. Once bearings 9a and 9b (see figure 2) are fitted to the rotor shaft ends Ba and Sb, the bearings are contained within stationary supports 10 and 11 (see figure 2). Cylindrical tube 3 rotates freely about its axis when driven via shaft ends Sa or Sb. Fixed to cylindrical tube 3 are permanent magnets ~2 and 13 which rotate with the cylindrical tube 3 when the generator operates.

[20] The magnets are onented so that their like poles oppose (in this case the north poles) resulting in magnetic flux lines being directed radially outwardly from central zone 14 of cylindrical tube 3. Throughout the specification the term 'central zone' can be taken to mean that region in the centre of the rotor wherein the output voltage is generated when the rotor [25] is rotated. A cavity 15 is formed between two shaped cast iron pole pieces 20 and 21 between magnets 12 and ~3.

As well as havuig a central zone 14, cylindrical tube 3 includes end zones 18 and 19 wherein the central zone 14 is disposed between the end zones.

[30] Referring to figure 2 there is shown an exploded view of the generator of figure I including the rotor 2 of figure 1, current collectors 22 and 23 and their interrelationship with the cylindrical tube 3.

[5] Figure 2 also shows connected to electrically conductive cylindrical tube 3 end caps 6 and 7 terminating in rotor shaft ends Sa and Sb respectively.

Current collectors 22 and 23 both of which are identical are located at contacts 32 and 33 in end zones 18 and 19 respectively of cylindrical tube 3. Each collector is located along [10] cylindrical tube 3 in a neutral region of each end zone in a flux field where the concentration of flux is low. As current collectors 22 and 23 are identical, only current collector 22 will be described in detail and with reference to figure 3 below to avoid duplication.

As the rotor of the generator I is rotated, a voltage potential develops between contacts 32 [15] and 33. Power output is drawn from the generator via the two current collectors 22 and 23. The mercury provides the electrical contact between the cylindrical tube 3 and current collectors 22 and 23 which are in electrical contact with output terminals 24 and 25 (see figure 8). It has been found that using the pole configuration shown in figure 1 that 3 to 4 times the voltage output of a standard homopolar generator may be obtained using magnets [20] having the same field strength.

Referring now to figure 3 there is shown an exploded isometric view of a typical current collector. Figure 3 shows an enlargement of the current collector 22 of figure 2 comprising two parts 27 and 28 which preferably are symnietrical about their plane of separation and [25] which together form a contact body housing 26 (see figure 4). Body parts 27 and 28 are preferably manufactured from a high conductivity material eg. copper. To form current collector 22 each of parts 27 and 28 which include semi circular bores 29a and 29b respectively receive substantially semi circular and preferably plastic sealing elements 30a, 30b, 30c and 30d which when in situ and mated together form circular recess 31 (see figure 4). [30] In use, recess 31 receives liquid mercury which provides the electrical contact with contact 32 on cylindrical tube 3. Contact 32 rotates in circular recess 31. Body parts 27 and 28 are mated together by means of bolts or locking screws 34 and 35.

Figure 4 shows the current collector 22 of figure 3 assembled. When body parts 27 and 28 [5] are mated together a seal is created by plastic seal 30 formed by sealing elements 30a, 30b, 30c and 30d thereby preventing the escape of liquid mercury during operation of the generator. It will be appreciated that plastic seal 30 can be an integral member as an alternative to formation by separate elements. There is a small clearance between sealing elements 30a, 30b, 30c, 30d and the rotor 2. Screw threads are machined on the sealing [10] lands 58, 59, 60, 61 (see figure 1) of the cylindrical tube 3, so that any leakage of mercury is returned when the rotor is rotating to recess 3 1 - the electrical contact zone.

As an alternative to use of liquid metal contacts, electrical brushes which are widely used in electrical machinery may be used. However, the generator, according to the present [15] invention produces low voltage at very high currents which is generaijy unsuitable for solid sliding contacts. The preferred contacts are conducting liquid metals such as mercury or eutectics such as sodium-potassium or gallium-indium. The use of liquid metal electrical contacts gives the advantage of lower electrical resistance, lower mechanical friction and low wear.

[20] Electrical contacts 32 and 33 are machined into the cylindrical tube 3. Preferably a number of annular ridges 32a and 33a may be formed on contacts 32 and 33 respectively. Contacts 32 and 33 are when surrounded by current collectors 22 and 23 separated by a very small clearance between the conductive surface of recess 3 1 (in the case of contact housing body 26)[25]. There is a corresponding arrangement in contact assembly 23. Preferably that clearance for each contact is 0.5mm or less.

Each of current collectors 22 and 23 include capillary lines. As the capi]lary line arrangements for current collectors 22 and 23 are the same, the following description will [30] relate to the capillary line for current collector 22 shown assembled in figure 4. Referring to figure 3 it can be seen that body part 28 of current collector 22 includes mercury reservoir 44 which feeds into capillary line 42 with flow of liquid metal into recess 31 being controlled by means of valve 46. In use, rotor 2 is rotated and then liquid metal is introduced from reservoir 44 via the capillary line 42 to the space between the circumferential contact 32 [5](see figure 1) and recess 31 of current collector 22 (see figure 3).

Centrifugal forces and viscous drag cause liquid metal to be taken up on the contacts 32 and 33 of cylindrical tube 3 to form a circumferential ring of liquid metal bead encircling those contacts. Thus, for current collector 22 mercury is in contact with the surfaces within recess [10] 31 of contact body housing 26. Similarly for contact assembly 23. Because the liquid metal bead is held in place by a combination of centrifigal and viscous forces the clearance between contact 32 and recess 31 can be quite large (for instance; 2mm). Once the cylindrical tube is rotating and the liquid metal has been introduced, the apparatus will operate equally well either horizontally or vertically. For satisfactory operation the liquid [15] metal should wet the inner surfaces of recess 3 1. In the case of mercury, to a achieve proper amalgamation it is preferred that a process is employed to remove oxide from the surface of the body parts 27 and 28 prior to introduction of the mercury.

Referring to figure 5 there is shown the rotor 2 of figure 1 seated in part of current collectors [20] 22 and 23. It can be seen that contacts 32 and 33 locate in recesses 31 and 37 respectively. Recess 31 is formed by plastic seal elements 30a, 30b and recess 37 is formed by seal elements 38a and 38b. Seal elements 30a, 30b, 38a and 38b engage respectively sealing lands SB, 59, 60 and 61 which have helical threads which urge any mercury that escapes recesses 31 and 37 back into those recesses when the rotor rotates.

[25] Referring now to figure 6 there is shown a long section view of the rotor 2 of figure 1 showing the disposition of the flux lines relative to the cylindrical tube 3. Cylindrical tube 3 is shown including permanent magnets 12 and 13. Magnets 12 and 13 are preferably permanent magnets and may either be conventional magnets, rare earth metal magnets or [30] super conducting magnets. The magnets 12 and 13 may each be formed from a plurality of magnetic elements or other magnetic material. As cylindrical tube 3 is preferably formed of a high strength, high electrical conductivity copper alloy the cylindrical tube can be rotated at very high speeds. The polar opposititíon configuration of magnets 12 and] 3 produce flux lines which pass through and exit the central zone of cylindrical tube 3 in a direction that is perpendicular to the axis of the cylindrical tube 3 in central zone 14. From figure 6 it can be seen that there is a concentration of radial flux in central region 14 as depicted by flux lines 39. Flux lines 40a, b, c and d are concentrated in end zones 18 and 19 as shown.

Rotation of the conductive cylindrical tube 3 with the magnetic flux generates a potential difference between contacts 32 and 33 (refer figure 1). The electric potential between terminals 32 and 33 is given by the relationship

$$E = 10^{-8} .v. Bn\ dl$$

where:

E is the potential difference between the contacts 32 and 33 in volts,

Bn is the flux density (in Gauss) normal to the surface of cylindrical tube 3, i.e. acting radially to the axis of rotation of the rotor.

l is the distance in cm between contacts 32 and 33; and

v is the tangential velocity of the surface of cylindrical tube 3 in cm/second.

Accordingly, I will effectively be the length of cylindncal tube 3 adjacent poles 16 and 17.

As the potential difference is proportional to the tangential velocity of the cylinder it is preferable that the cylindrical tube 3 be built as large as possible to achieve optimal output voltage, and be rotated as fast as possible, for example, up to 100,000 rpm or beyond if physical limits permit.

Due to the high currents generated by the generator, super conducting materials are particularly suitable to be incorporated in or used with cylindrical tube 3.

A generator of the type hereinbefore described can produce very high output currents (multiples of kiloamperes) at low voltages. The withdrawal of high electrical currents from the generator results in a magnetic field consisting of circular flux tines enclosing the central zone 14 of the cylindrical tube 3. A method of cancelling or at least minimising these effects will now be described with reference to figure 7 of the drawings.

Referring to figure 7 there is shown a schematic representation of a generator similar to that depicted in figure 1 including magnetic compensation means. In the embodiment shown a conductive compensation tube 48 is positioned about and spaced apart from, the central zone 14 of cylindrical tube 3. One end 49 of compensation tube 48 is electrically connected to contact 50 by conductor 5 1. The opposite end *52* of compensation tube 48 is connected to outward terminal 53 of the generator by conductive connection 54. Compensation tube 48 remains stationary while cylindrical body 3 rotates relative thereto. Compensation tube 48 produces compensatory circular magnetic flux which cancels the field generated by withdrawal of current. This works in the same manner as a coaxial cable; whereby equal currents flow in opposite directions thus the magnetic fields thereby produced cancel each other. The cancellation of the magnetic fields due to the high currents in the generator is important, since the field distortion (armature reaction) produced by these currents when uncompensated can limit the power output of the machine by altering the perpendicularity of the flux lines to the rotating cylindrical tube 3.

Referring now to figure B there is shown an isometric view of a filly assembled generator including output terminals 24 and 25 in communication with current collectors 22 and 23 with spacing block 56 therebetween. Outside current collectors 22 and 23 are bearing supports 10 and 11 which receive bearings 9a and 9b (see figure 2). Outside bearing support 11 is drive wheel 57.

Figure 9 shows the assembled generator of figure 8 with an electric motor 62 connected thereto via drive belt 63 which engages drive wheel 57.

It is thus seen that the present invention provides a generator having improved performance over known homopolar generators. Particularly, in this invention the arrangement of the magnets in polar opposition provides increased flux concentrations, increasing the output voltage of the generator for the same strength of magnet employed. The magnetic compensation method of the invention allows the generator to operate at high power outputs without substantial effect on the perpendicularity of the flux lines. Finally, contacts using liquid metal reduce the electrical and frictional losses of the generator.

Where in the foregoing description reference has been made to integers or components having known equivalents then such equivalents are herein incorporated as if individually set forth.

For example, it is to be appreciated that cylindrical tube 3 need not by cylindrical, although a cylindrical tube is preferred.

The magnets which are the source of flux must rotate integrally with the cylindrical tube 3 in polar opposition with flux lines parallel to the axis of rotation even though the output voltage is generated by a 900 curvature of these lines intersecting the rotating conductive cylindrical tube 3 No fixed external pole pieces or magnets can be used for the purpose of magnetic field enhancements.

As an example of the performance of the generator using known magnets, it could be expected that a voltage output of 1.5 V.D.C. could be achieved at a rotational speed of 12,000 rpm. A power output of 10KW maybe obtained from the machine by the withdrawal of 6,670 amperes of electrical current. At this current under 400 watts will be dissipated in the rotor as heat. A realistic determination of allowable current flow based on rotor heating would be 12,000 amperes, with 6,000 amperes taken from each side of the machine. Generator drive can be achieved by use of any applicable electrical, mechanical, internal combustion, water or wind power.

Although this invention has been described by *way* of example it is to be appreciated that improvements and/or modifications may be made thereto without departing from the scope or spirit of the invention, such as but not limited to:

use of low friction bearings, for example air bearings;

operating the device in a vacuum sealed environment to reduce windage drag;

modifications to the magnetic field to enhance the performance, utility and regulation of the generator.

The claims defining the invention are as follows:

1. A single piece homopolar generator for use alone or in combination with a like or known generators comprising;

current collectors co-operating with a rotor body wherein the rotor body comprises;
at least one electrically conductive member,

a central zone between end zones,

at least two axially aligned magnets, arranged so that like poles of the magnets oppose to produce flux lines which pass through and exit the central zone of said rotor body in a direction radial to the axis of rotation;

wherein the magnets in polar opposition rotate with the conductive member or members and wherein the north/south polar alignment of each magnet is axial; and

electrical contacts proximate each end zone and an electrical path or paths proximate the radial extremities of the rotor between each contact formed by said electrically conductive member or members.

2. A generator according to claim 1 wherein said electrically conductive member or members comprise(s) a cylindrical tube(s) and wherein the magnets in each said tube(s) are spaced apart and are disposed in axial alignment with the axis(es) of the tube(s).

3. A generator according to claim 2 wherein the rotor comprises one cylindrical tube and the generator includes current collectors which connect electrically with the cylindrical tube by sliding brush or liquid metal contacts or both, wherein the current collectors are each located along the tube in a neutral region of each end zone in a flux field where the concentration of flux lines is low.

4. A generator according to claim 3 wherein each current collector includes an element which provides a seal to prevent egress of liquid metal from a current collecting zone between the tube and each current collector.

5. A generator according to claim 4 wherein the niagnets are either superconductive solenoid repelling magnets or rare earth magnets such as Nd_2 Fe_{14} B or SaCo.

6. A generator according to claim 5 wherein the speed of the generator is within a range up to 100,000 rpm.

7. A generator according to claim 6 wherein the tube is supported by shafts extending from each end and which bear on fixed bearing supports.

8. A generator according to claim 7 wherein the cylindrical tube is formed from superconducting materials.

9. A generator according to claim 7 wherein the cylindrical tube is manufactured from Beryllium-Copper alloy.

10. A generator according to claim B or 9 wherein the brushes are carbon or copper graphite.

11. A generator according to claim B or 9 wherein the liquid metal is either mercury, sodium-potassium eutectic or gallium~indium eutectic as the conductive material.

12. A generator according to any of the foregoing claims wherein multiple generators are connected in senes.

13. A generator according to claim I wherein the generator is adapted with cooling means whereby a cooling liquid or gas is passed through the rotor and/or current collectors of the machine during operation.

14. A rotor for use with a generator as hereinbefore described, the rotor comprising;

a rotor body comprising;
at least one electrically conductive member,

a central zone between end zones,

at least two axially aligned magnets, arranged so that like poles of the magnets oppose to produce flux lines which when the rotor is in use pass through and exit the central zone of said rotor body in a direction radial to the axis of rotation,

wherein the magnets in polar opposition rotate with the conductive member or members and wherein the north/south polar alignment of each magnet is axial;

and electrical contacts proximate each end zone and an electrical path or paths proximate the radial extremities of the rotor between each contact formed by said electrically conductive member or members.

15. A rotor according to claim 14 wherein said electrically conductive member or members comprise(s) cylindrical tube(s) and wherein the magnets in each said tube(s) are spaced apart and are disposed in axial alignment with the axis(es) of the tube(s).

16. A rotor according to claim 15 wherein the rotor comprises one cylindrical tube.

17. A rotor according to claim 16 wherein the contacts are circumferential about the cylindrical tube.

18. A rotor according to claim 17 wherein the electrical contacts include annular ridges.

19. A rotor according to claim 18 wherein the central zone includes two shaped cast iron pole pieces forming a cavity therebetween.

20. A current collector for use with a generator as hereinbefore descnbed, the current collector comprising,

a two part body one of which pans is detachably attached to the other part, wherein when the two parts are attached a central bore is formed which receives a rotor, means for fitting at least partially within said bore to create a seal between the rotor and the outside of the bore wherein said means allows the formation of a circumferential recess within the bore in which an electrically conductive material is located and which is in electrical contact with electrical contacts on the rotor.

21. A current collector according to claim 20 wherein the two parts are symmetrical about their line of separation.

22. A current collector according to claim 21 wherein said sealing means comprises a plastic insert having four elements two of which engage one part of the current collector and two of which engage the other part.

23. A current collector according to claim 22 wherein the electrically conductive material is mercury or liquid metal eutectics.

24. A current collector according to claim 23 wherein one part of the current collector includes a passage in communication with the recess in the bore and which receives an outlet of a mercury or liquid metal eutectic reservoir, the reservoir including a valve which regulates the flow of said mercury or liquid metal eutectic from said reservoir via said passage into said recess.

25. A compensation tube disposed concentrically about the cylindrical tube of the rotor as hereinbefore described and which produces compensatory circular magnetic flux.

26. A compensation tube according to claim *25* wherein the compensation tube is connected to a first contact on the rotor and the other is connected to an output terminal of a generator as hereinbefore described.

27. A system for generating electricity using a single piece homopolar generator; the system comprising;

the single piece generator, having one moving part, the rotor, and in which the desired electrical potential is produced without mutual interaction of a stator, a power source to drive the generator, a field of energy influence within which the generator is situated and with which the generator interacts, wherein the interaction between the generator and the field influences the output of the generator by supplementing energy input to the generator from said power source.

Box I **Observations where certain claims were found unsearchable (Continuation of Item 1 of first sheet)**

This international search report has not established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:

2. ☐ Claim Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:

3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II **Observations where unity of invention is lacking (Continuation of item 2 of first sheet)**

This International Searching Authority found multiple inventions in this international application, as follows:

(a) Claims 1-19

Claims 1-19 define a single piece homopolar generator having a rotor with axially aligned magnets so that the magnetic poles oppose to produce flux lines.

(b) Claims 20-24

Claims 20-24 are directed to a current collector with a two part body defining a central zone that receives a rotor.

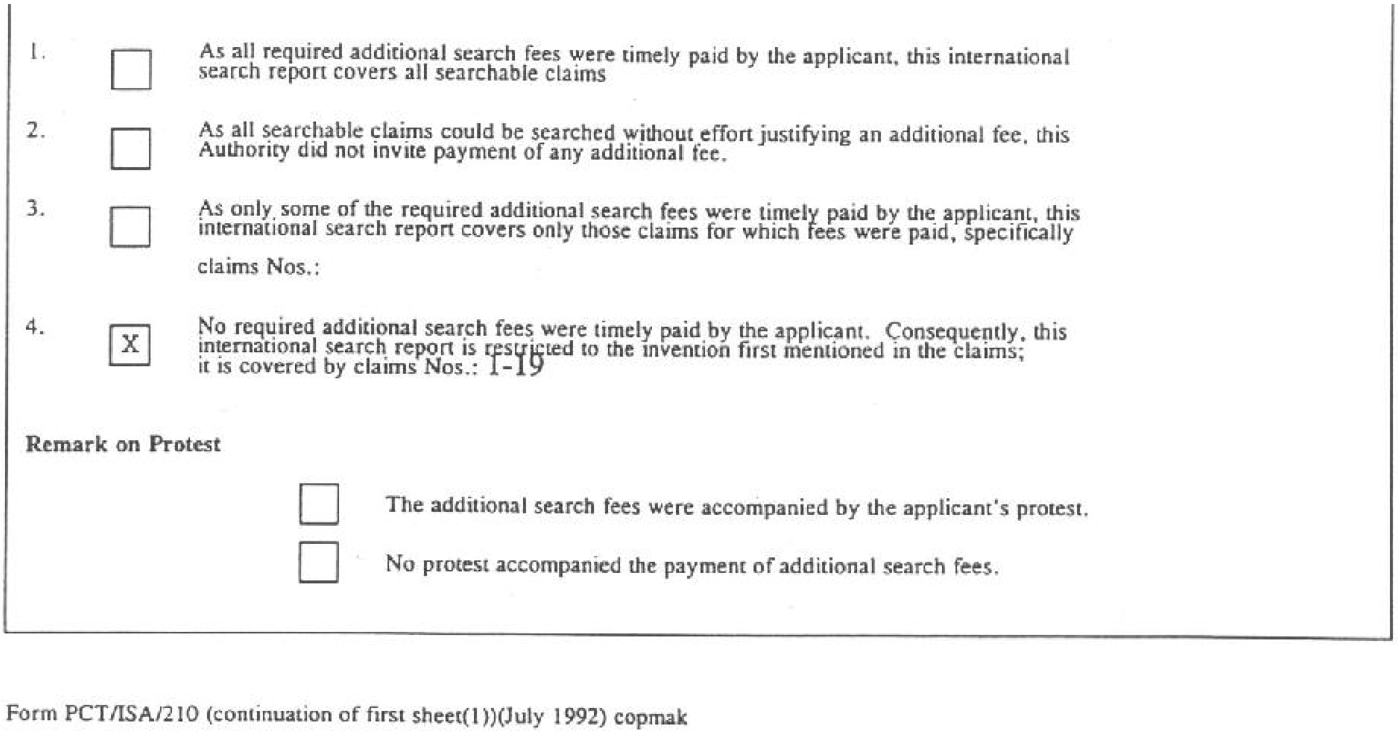
(c) Claims 25-26

Claims 25-26 define a compensatory tube which produces a compensatory circular flux.

(d) Claim 27

Claim 27 defines a system (any system) which uses a single piece homopolar generator.

Since the abovementioned groups of claims do not share any of the technical features identified, a "technical relationship" between the inventions, as defined in PCT rule 13.2 does not exist. Accordingly the international application does not relate to one invention or to a single inventive concept.



1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims

2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.

3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:

4. ☒ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.: 1-19

Remark on Protest

☐ The additional search fees were accompanied by the applicant's protest.

☐ No protest accompanied the payment of additional search fees.

(57) ABSTRACT

A resonant transformer connected between a ground terminal and elevated terminal draws current from the earth's electric field through a primary winding of the transformer. An impulse generator applies a high voltage impulse to the primary winding of the resonant transformer to cause current to flow from the ground terminal through the primary winding. The flow of current through the primary winding of the resonant transformer induces a current in the secondary winding, which may be converted and filtered to a usable form, e.g. 60 Hz AC or DC.

POWER RECEIVER FOR EXTRACTING POWER FROM ELECTRIC FIELD ENERGY IN THE EARTH

[0001] This application claims the benefit of U.S. Provisional Application No. 61/889,894, filed 11 Oct. 2013, the disclosure of which is incorporated herein by reference in its entirety.

TECHNICAL FIELD

[0002] The present invention relates generally to renewable energy, and more particularly to methods and apparatus for extracting energy from subsurface electrical fields beneath the earth's surface.

BACKGROUND

[0003] The earth and the ionosphere cavity may be viewed as a global electric circuit. Electrical currents are constantly flowing within the earth and its atmosphere. Within the earth, the majority of the earth's energy is carried by extremely low frequency (ELF) and ultralow frequency (ULF) waves in the 0-200 Hz frequency range. The earth's rotating magnetic field and positive lightning are two energy sources that sustain the ELF/ULF waves within the earth and the atmosphere.

[0004] A great deal of research has been devoted to studying the electric field present in the earth's ionosphere cavity. Joseph M. Crawley, the "Fair Weather Atmosphere as a Power Source", Proceedings ESA Annual Meeting on Electrostatics 2011; O. Jefimenko, "Operation of Electric Motors from Atmospheric Electric Field," American Journal of Physics, Vol. 39, Pgs. 776-779, 1971; M. L. Breuer, "Usability of Tapping Atmospheric Charge as a Power Source," Renewable Energy, Vol. 28, Pgs. 1121-1127, 2003. Numerous attempts have been made in the past to extract electrical energy from the earth's atmosphere. For example, U.S. Pat. No. 1,540,998 to Plauson describes a system for converting atmospheric electrical energy into usable power. These past attempts have been successful in producing only small amounts of power from the electrical field in the earth's ionosphere cavity. The modest success of these experiments compared to results from other renewable energy sources, such as solar and wind, has tempered further research and prevented widespread use of the electric field in the ionosphere cavity as an energy source.

SUMMARY

[0005] The present invention relates to a power receiver for extracting power from electric fields beneath the earth's surface. In embodiments of the present disclosure, a resonant transformer connected to a ground terminal draws current from the earth's electric field through the primary winding of the transformer. Current flow through the resonant transformer is induced by applying a high voltage impulse to the primary winding. The flow of current through the primary winding of the resonant transformer induces a current in the secondary winding, which may be converted and filtered to a usable form, e.g. 60 Hz AC or DC.

[0006] In some embodiments of the power receiver, the resonant frequency of the resonant transformers is below 200 Hz.

[0007] In some embodiments of the power receiver, the resonant transformer comprises a ferro-resonant transformer.

[0008] In some embodiments, the power receiver further comprises an elevated terminal.

[0009] In some embodiments of the power receiver, the primary winding of the resonant transformer is connected between the ground terminal and elevated terminal.

[0010] In some embodiments of the power receiver, the elevated terminal comprises an upper capacitive plate coupled to the earth's ionosphere cavity.

[0011] In some embodiments of the power receiver, the impulse generator comprises the upper capacitive plate and a spark gap connected between the upper capacitive plate and the primary winding of the resonant transformer. The spark gap comprises a pair of electrodes separated by a gap and configured to generate a spark when a voltage difference between the electrodes reaches a predetermined level.

[0012] In some embodiments of the power receiver, the impulse generator comprises a pulse generator for generating low voltage pulses, a step-up transformer for converting the low voltage pulses provided by the pulse generator to high voltage impulses, and a spark gap connected between the step-up transformer and the primary winding of the resonant transformer to generate a spark responsive to the high voltage impulses from the step-up transformer.

[0013] In some embodiments of the power receiver, the impulse generator comprises a pulse generator for generating low voltage pulses, and a step-up transformer connected to the primary winding of the resonant transformer for converting the low voltage pulses provided by the pulse generator to high voltage impulses.

[0014] In some embodiments of the power receiver, the impulse generator comprises a solid state spark generator.

[0015] In some embodiments of the power receiver, the resonant transformer includes a capacitor connected in parallel with the primary winding.

[0016] In some embodiments of the power receiver, the resonant transformer includes a capacitor connected in series with the primary winding between the impulse generator and the elevated terminal.

[0017] In some embodiments, the power receiver comprises multiple resonant transformers having primary windings connected in parallel between the ground terminal and the elevated terminal.

[0018] In some embodiments of the power receiver, the resonant transformers have different resonant frequencies.

[0019] In some embodiments of the power receiver, the resonant frequencies of the resonant transformers are all below 200 Hz.

[0020] In some embodiments of the power receiver, the resonant frequencies of the resonant transformers are matched to respective Schumann resonances.

[0021] Another embodiment of the power receiver comprises a resonant circuit connected to a ground terminal disposed below the surface of the earth, an impulse generator for generating and applying a high voltage electrical impulse to the resonant circuit to induce current flow from the ground terminal through the resonant circuit, and a power conversion circuit connected to the resonant circuit to convert electrical current flowing through the resonant circuit to a desired form. The resonant circuit has a resonant frequency below 200 Hertz.

[0022] In some embodiments of the power receiver, the resonant circuit comprises a resonant transformer having a primary winding, a secondary winding, and resonant capacitor connected in series with the primary winding.

[0023] In some embodiments of the power receiver, the resonant circuit comprises multiple resonant transformers having primary windings connected in parallel to the ground terminal.

[0024] In some embodiments of the power receiver, the resonant transformers have different resonant frequencies.

[0025] In some embodiments of the power receiver, the resonant frequencies of the resonant transformers are all below 200 Hz.

[0026] In some embodiments of the power receiver, the resonant frequencies of the resonant transformers are matched to respective Schumann resonances.

[0027] Other embodiments of the disclosure comprise a ground terminal for a power receiver. In one embodiment, the ground terminal comprises a ground shaft configured for insertion beneath the surface of the earth, a hollow cylinder surrounding the ground shaft and having a plurality of openings, and a plurality of ground wires connected at one end to the ground shaft. The ground wires are wound around the ground shaft and have free ends protruding through respective openings in the hollow shaft so that rotation of the ground shaft relative to the hollow cylinder causes the ground wires to extend radially into the earth.

[0028] Other embodiments of the disclosure comprise methods of extracting power from the earth. In one embodiment, the method comprises applying a high voltage impulse to resonant circuit coupled to a ground terminal disposed beneath the surface of the earth to initiate resonance in the resonant circuit and induce the flow of current from the ground terminal to the resonant circuit, and converting the current flowing from the ground terminal into the resonant circuit into a useful form.

[0029] In some embodiments of the method, the resonant circuit comprises a resonant transformer including a primary winding coupled to the ground terminal and a second winding coupled to a power converter, and applying a high voltage impulse to resonant circuit comprises applying a high voltage impulse to the primary winding of the resonant transformer.

[0030] In some embodiments of the method, applying a high voltage impulse to the primary winding of the resonant transformer comprises applying an impulse in the range to 10,000 to 40,000 volts to primary winding of the transformer.

BRIEF DESCRIPTION OF THE DRAWINGS

[0031] FIG. **1** illustrates a first exemplary embodiment of a power receiver.

[0032] FIG. **2** illustrates a second exemplary embodiment of a power receiver.

[0033] FIG. **3** illustrates a third exemplary embodiment of a power receiver.

[0034] FIG. **4** illustrates a fourth exemplary embodiment of a power receiver.

[0035] FIG. **5** illustrates a fifth exemplary embodiment of a power receiver.

[0036] FIG. **6**A is an exploded perspective view of an exemplary ground antenna array for the power receiver.

[0037] FIG. **6**B is a perspective view of an assembled ground antenna array before being deployed.

[0038] FIG. **6**C is a perspective view of an assembled ground antenna array after being deployed.

[0039] FIG. **7**A is a side view of an insertion tool for installing the ground antenna array.

[0040] FIG. **7**B is a top view of the insertion tool for installing the ground antenna array.

[0041] FIG. **7**C is a bottom view of the insertion tool for installing the ground antenna array.

DETAILED DESCRIPTION

[0042] Referring now to the drawings, a power receiver for extracting energy from the earth's electric field are illustrated and indicated generally by the numeral **10**. Various embodiments of the power receiver **10** are described and similar reference numbers are used throughout the description to indicate similar components.

[0043] The power receiver **10** converts energy in the ELF/ULF waves to useful form, e.g. 60 Hz AC or DC. The power receiver **10** is essentially a resonance circuit that resonates at the natural resonance frequencies in the earth's electric field. These resonance frequencies, known as Schumann resonance frequencies, occur at 7.83 Hz, 14.3 Hz, 20.8 Hz, 27.3 Hz, and 33.8 Hz. A high voltage impulse initiates resonance within the power receiver **10**. In the resonant mode, the impedance of the power receiver **10** is reduced to near zero thus inducing ground currents to flow into the power receiver **10** where the ground currents are converted to useful form.

[0044] FIG. **1** illustrates a first embodiment of the power receiver **10**. The power receiver **10** comprises a resonant transformer **30** connected between an elevated terminal **15** and ground terminal **25**. In this embodiment, the elevated terminal **15** is capacitively coupled to electric fields within the earth's ionosphere cavity and functions as an upper capacitive plate. A lower capacitive plate **20** is connected to the ground terminal **25** beneath the surface of the earth.

[0045] The resonant transformer **30** comprises a primary winding **35**, secondary winding **40**, ferromagnetic core **45**, and capacitor **50**. One end of the primary winding **35** is connected to the lower capacitive plate **20** and ground terminal **25**. The opposite end of the primary winding **35** is connected via a spark gap **90** to the elevated terminal **15**. The capacitor **50** is connected in parallel with the primary winding **35** of the resonant transformer **30** to form an LC circuit **55** with a resonance frequency range of between about 0.1 and 200 Hz. In a preferred embodiment, the resonant transformer has a Q of about 10 or greater and resonance frequency in the range of about 0.1-200 Hertz. For example, the resonant transformer **30** may have a resonance frequency of about 7.83 Hz, the fundamental Schumann resonance frequency. The secondary winding **40** of the resonant transformer **30** is connected to a power converter **110** as will be hereinafter described in greater detail. The power converter **110** converts the energy extracted from the earth's electric field by the power receiver **10** into a usable form for driving a load **140**.

[0046] The elevated terminal/upper capacitive plate **15** comprises an insulated, dish-shaped plate with a large radius of curvature. The capacitance and resistance of the elevated terminal is chosen for receiving broadband electric field frequencies in the 0-200 Hz range. The upper capacitive plate **15** is sized to maximize to the extent practical coupling with the electric field in the earth's ionosphere cavity.

[0047] The lower capacitive plate **20** is also a dish-shaped plate with a large radius of curvature. One function of the lower capacitive plate **20** is to collect charge from the earth's ground currents and provide an instantaneous source of current as hereinafter described. The capacitance and resistance of the lower capacitive plate **20** is selected to promote the flow of current from the ground with minimal losses.

[0048] The spark gap **90** connected between the elevated terminal **15** and resonant transformer **30** comprises a pair of electrodes **95**, **100** separated by an evacuated air gap **105**. Electrode **95** is connected to the upper capacitive plate **15**. Electrode **100** is connected to the resonant transformer **30**. The spark gap **105** prevents electrical discharge from the upper capacitive plate **15** to the earth's ionosphere cavity. The spark gap **90** in combination with the elevated terminal **15** function as an impulse generator that applies a high voltage impulse of about 10,000-40,000 volts to the primary winding **35** to initiate resonance in the transformer **30**.

[0049] In operation, the capacitive coupling of the upper capacitive plate **15** induces a high voltage operating current in the upper capacitive plate **15**. The upper capacitive plate is connected to a first electrode **95** to the spark gap **90**. When the voltage difference between the electrodes **95** and **100** reaches a threshold, a spark forms across the electrodes **95**,**100** and a high voltage impulse is applied to the primary winding **35** of the resonant transformer **30**. This high voltage impulse initiates resonance within the transformer **30**.

[0050] In resonant mode, the impedance of the resonance transformer is reduced to nearly zero allowing current to flow from the capacitive plate **20** and ground terminal **25** through the primary winding **35** of the transformer **30**, which in turn induces current in the secondary winding **40**. Power converter **110** converts the current flowing through the secondary winding **40** into a usable form for driving a load **140**. The transformer **30** will continue to resonate for a short period of time. By providing high voltage impulses to the primary winding **35** of the resonant transformer **30** at periodic intervals, it is possible to maintain a continuous flow of current from the earth into the resonant transformer **30**, thus producing a continuous supply of power.

[0051] FIG. **2** discloses a second embodiment of the primary receiver **10**. This embodiment includes a resonant transformer **30** connected between an elevated terminal **15** and ground terminal **25**. The resonant transformer **30** comprises a primary winding **35**, secondary winding **40**, ferromagnetic core **45** and a high voltage capacitor **50**. One end of the primary winding **35** is connected to the ground terminal **25**. The opposite end of the primary winding **35** is connected to the elevated terminal **15**. The capacitor **50** has a capacitance of about 0.01 micro-farads. In contrast to the previous embodiment, capacitor **50** is connected in series with the primary winding **35** and elevated terminal **15** and forms a LC circuit **55** with a Q of about 10 or greater and a resonance frequency in the range of about 0.1 to 200 Hz. In a preferred embodiment, the resonance frequency of the transformer **30** is 7.83 Hz, the fundamental Schumann resonance frequency. An impulse generator **60** is connected between the primary winding **35** of the resonant transformer **30** and the series capacitor **50** and applies a high voltage impulse to the primary winding **35** of the resonant transformer **30**. A battery **130** or other external power source supplies power to the impulse generator **60**. As previously described, the high voltage impulse applied by the impulse generator **60** initiates resonance within the resonant transformer **30** inducing current flow from the ground terminal **25** into the primary winding **35** of the resonant transformer **30**. The flow of current from the ground terminal **25** through the primary winding **35** induces current in the secondary winding **40**. Power converter **110** converts the electrical energy in the current flowing through the primary winding **40** into a usable form.

[0052] In contrast to the first embodiment, it is not required to capacitively couple the elevated terminal **15** in the second embodiment to the earth's ionosphere cavity. Rather, the elevated terminal **15** in this embodiment provides lightning protection and dissipates some of the energy flowing into the power receiver **10** to the earth's ionosphere cavity. Also, in contrast to the first embodiment, the capacitor **50** is connected in series between the primary winding **35** of the transformer **30** and the elevated terminal **15**. Those skilled in the art will appreciate that the capacitor **50** could also be connected in parallel rather than series with the primary winding **35** as shown in FIG. **1**. Another difference is that the impulse generator **60** has an external power source. The amount of energy generated by the power receiver **10**, however, is far greater than the energy needed to generate high voltage impulses. The first embodiment does not require an external power source to generate high voltage impulses.

[0053] FIG. **3** illustrates a third embodiment of the power receiver **10**. This embodiment is essentially the same as the embodiment shown in FIG. **2**. The main difference is that a center tap of the primary winding **35** in the resonant transformer **30** is connected to an electrical ground **55**. It should be appreciated that the electrical ground **55** may be different than the earth ground. When the center tap of the resonant transformer **30** is grounded at a distance away from the ground terminal **25** (e.g. 50 ft to 100 ft), the power receiver **10** becomes a transmitter via the ground loop formed.

[0054] FIG. **4** illustrates the power receiver **10** of FIG. **2** in greater detail. The power receiver includes a resonant transformer **30** connected between a ground terminal **25** and an elevated terminal **15**. The resonant transformer **30** includes a primary winding **35**, secondary winding **40**, ferromagnetic core **45** and series capacitor **50** configured as previously described. The resonant transformer **30** may have a Q of about 10 and a resonance frequency in the range of about 0.1 to 200 Hz. The resonant transformer **30** may be made using an Allison transformer (part #1530BP120R) connected in series with a 0.01 micro-farad capacitor, such as the Condensor Products high voltage capacitor (part #TC 103-17-125). An impulse generator **60** is connected between the primary winding **35** of the resonant transformer **30** and the series capacitor **50** and applies a high voltage impulse in the range of about 10,000 to 40,000 volts to the primary winding of the transformer **30**. A battery **130** or other external power source supplies power to the impulse generator **60**. The power converter **110** connects to the secondary winding **40** of the resonant transformer **30** for converting current in the secondary winding of the transformer to a useful form.

[0055] The impulse generator **60** comprises a pulse generator **65** for generating low voltage pulses, a step-up transformer **80** for converting the low voltage pulses from the pulse generator **65** to high voltage pulses, and a spark gap **90** for generating sparks responsive to the high voltage pulses from the step-up transformer **80**.

[0056] The pulse generator **65** comprises a square wave generator **70** and solid state relay **75**. The square wave generator **70** generates a digital pulse stream. In one embodiment, the digital pulse stream generates a square waveform with a frequency of about 7.83 Hz. The frequency of the digital pulse stream is selected to match the resonance frequency of the transformer **30**, though such is not necessarily required. The pulse stream output from the square wave generator **70** is applied to the solid state relay **75**. The solid state relay **75** is connected between a battery or other power source and a first winding of the step-up transformer **80**. The solid state relay **75** functions as a switch that is activated responsive to the waveform from the square wave generator **70** to provide a continuous stream of low voltage pulses from the battery to the first winding of the step-up transformer **80**. A 1 ohm resistor is connected between the solid state relay **75** and step-up transformer **80**.

[0057] The step-up transformer **80** converts the low voltage pulses from the pulse generator **65** to high voltage pulses that are applied to the spark gap **90**. The step-up transformer has a 0.5 micro-farad capacitor connected in parallel with the primary winding of the step-up transformer **80**. The step-up transformer produces pulses at the output of about 30,000 to 40,000 volts.

[0058] The spark gap **90** comprises a pair of electrodes **95**, **100** separated by an air gap **105**. As previously described, when the voltage potential between the electrodes **95**, **100** reaches a threshold, a spark forms between the electrodes **95**, **100** and supplies a nearly instantaneous, high voltage impulse to the primary winding **35** of the resonant transformer **30**. This high voltage impulse initiates resonance in the resonant transformer **30** inducing current flow from the ground terminal **25** through the primary winding **35** of the resonant transformer **30**.

[0059] The power converter **110** comprises a bridge rectifier **115**, filter capacitor **120**, charge controller **125**, and inverter **135**. The bridge rectifier **115** converts the AC current flowing through the secondary winding **40** of the resonant transformer to a DC current. a Filter capacitor **120** removes unwanted frequencies from the DC current. The filter capacitor **120** has a capacitance of about 1000 micro-farads. The DC current is input to the charge controller **125**. The charge controller **125** may, for example, comprise a maximum power point tracking (MPPT) charge controller, which is commonly used in solar power generating systems. The charge controller **125** applies a small amount of energy to a battery **30** to charge the battery **130**. As previously noted, the battery **130** serves as a power source for the impulse generator **60**. The remaining current is supplied to an inverter **135**, which converts the DC current to an AC current with a desired voltage and frequency, e.g., 120 volts/60 Hz AC. The power converter **110** as shown in FIG. **4** may be utilized in the embodiment shown in FIGS. **1**, **2** and **3**.

[0060] FIG. **5** illustrates a power converter **10** according to another embodiment. The power converter **10** comprises a plurality of resonant transformers **30** connected between a ground terminal **25** and elevated terminal **15**. Each of the resonant transformers **30** comprises a primary winding **35**, secondary winding **40**, ferromagnetic core **45** and series capacitor **50**. The primary windings **35** of the resonant transformers **30** are connected in parallel. The secondary windings **40** are connected in series with the power converter **110**. An impulse generator **60** applies a high voltage impulse to the primary windings **35** of the resonant transformers **30**. A battery **130** or other external power source supplies power to the impulse generator **60**. The power converter **110** converts the current in the power converter circuit to a usable form for driving a load **140**.

[0061] In one embodiment, each of the resonant transformers **30** shown in FIG. **5** is configured to have a different resonant frequency. In one embodiment, the resonant transformers **30** are configured to resonate at frequencies of 7.83 Hz, 14.8 Hz, 20.3 Hz and 26.8 Hz respectively. Additional resonant transformers **30** could be added to operate at other resonance frequencies.

[0062] FIGS. **6**A-**6**C illustrate a high quality ground antenna array **200** which may be used as a ground terminal **25**. The ground antenna array **200** comprises a generally cylindrical ground shaft **205** disposed with a hollow cylinder **220** and a plurality of reinforced, heavy gauge ground wires **210** attached at one end to the ground shaft **205**. The ground shaft **205** and ground wires **210** should be highly conductive and have low resistance to supply current from the ground to the power receiver **10**. In one embodiment, the ground wires **210** may be copper or other highly-conductive metal. The end of the ground shaft may be pointed to facilitate insertion into the earth. A connection port on the ground shaft **220** is provided to electrically connect the ground antenna array **220** to the resonant transformer **30**.

[0063] The hollow cylinder **220** has external threads **25** to facilitate insertion into the ground. A rotator nut **235** is fixedly secured to the top end of the hollow shaft **220**. A square shaft **215** protrudes from the top end of the ground shaft **205** into the opening in the rotator nut **235**. FIG. **6**B. A tool **250**, shown in FIG. **7**, engages with the rotator nut **235** and square shaft **215** during insertion of the ground antennas array **200** into the ground as will be hereinafter described.

[0064] The insertion tool **250** is shown in FIG. **7**. The insertion tool **250** includes a tool body **255** having a first socket **260** on one side to fit the rotator nut **235** on the hollow cylinder **220** and a second socket **265** on the other side to fit the square shaft **215** on the ground shaft **205**. Arms **270** extend from the outer periphery of the tool body **255** for manually or mechanically turning the insertion tool **250**.

[0065] Before the antenna array **200** is deployed, the ground wires **210** are wound around the ground shaft **205** with the free ends protruding slightly from respective openings **230** in the hollow cylinder **220** to a distance not to exceed one half (½) the depth of the external threads **225** on the hollow cylinder **220**. FIG. **6**B illustrates the ground antenna array **200** before deployment. FIG. **6**C illustrates the ground antenna array in a deployed configuration.

[0066] Installation of the ground antenna array **200** is performed in two stages. In the first stage, a hole slightly smaller in diameter than the threads **235** of the hollow cylinder **220** is drilled into the Earth to a depth matching the length of the hollow cylinder **220** or slightly longer. The hole is filled with water and the water is allowed to soak into the soil. After the ground is softened, the hollow cylinder **220** is rotated using the insertion tool **250** to insert the ground antenna array **200** into the ground. The first socket **260** of the insertion tool **250** is engaged with the rotator nut **230** and the insertion tool **250** is turned by hand or a mechanized rotating shaft fitted and attached to the tool arms **270** to thread the ground assembly into the hole. During the initial insertion of the ground antenna array **200**, the ground shaft **205** is fixed to the hollow shaft **220** and rotates with the hollow shaft. The hollow cylinder **220** is rotated until it reaches the full depth of the hole.

[0067] Once the ground antenna array **200** has been fully inserted into the earth, the insertion tool **250** is flipped over and the second socket **265** of the insertion tool **250** is engaged with the square shaft **215**. The insertion tool **250** is turned by hand or a mechanized rotating shaft fitted and attached to the tool arms **270** to rotate the ground shaft **205**. During the second phase, the ground shaft **205** rotates freely inside the hollow cylinder **220**. Rotation of the ground shaft **205** causes the reinforced ground wires **210** to extend radially into the earth. The ground shaft **220** is rotated until the ground wires are fully extended. The ends of the ground wires may be sharpened to aid in the extension of the ground wires during the second phase.

[0068] After the ground antenna array **200** is deployed, a connection cable **280** is attached to a connection port **240** on the ground shaft **220** to electrically connect the ground antenna array **220** to the resonant transformer **30** in the power receiver **10**.

What is claimed is:

1. A power receiver for extracting electrical energy from the earth's electric field, said power receiver comprising:

a resonant transformer connected to a ground terminal disposed below the surface of the earth;

an impulse generator for generating and applying a high voltage electrical impulse to a primary winding of the resonant transformer to induce current flow from the ground terminal through the primary winding of the transformer; and

a power conversion circuit connected to a secondary winding of the resonant transformer to convert electrical current flowing through the secondary winding to a desired form.

2. The power receiver of claim **1** wherein a resonant frequency of the resonant transformers is below 200 Hz.

3. The power receiver of claim **1** wherein the resonant transformer comprises a ferro-resonant transformer.

4. The power receiver of claim **1** further comprising an elevated terminal, and wherein the primary winding of the resonant transformer is connected between the ground terminal and elevated terminal.

5. The power receiver of claim **4** wherein the elevated terminal comprises an upper capacitive plate coupled to the earth's ionosphere cavity.

6. The power receiver of claim **5** wherein the impulse generator comprises:

the upper capacitive plate;

a pair of electrodes separated by a spark gap, said electrodes connected between the upper capacitive plate and the primary winding of the resonant transformer and configured to generate a spark when a voltage difference between the electrodes reaches a predetermined level.

7. The power receiver of claim **1** wherein the impulse generator comprises:

a pulse generator for generating low voltage pulses;

a step-up transformer for converting the low voltage pulses provided by the pulse generator to high voltage impulses;

a spark gap connected between the step-up transformer and the primary winding of the resonant transformer to generate a spark responsive to the high voltage impulses from the step-up transformer.

8. The power receiver of claim **1** wherein the impulse generator comprises:

a pulse generator for generating low voltage pulses;

a step-up transformer connected to the primary winding of the resonant transformer for converting the low voltage pulses provided by the pulse generator to high voltage impulses.

9. The power receiver of claim **1** wherein the impulse generator comprises a solid state spark generator.

10. The power receiver of claim **1** wherein said resonant transformer includes a capacitor connected in parallel with the primary winding.

11. The power receiver of claim **1** wherein said resonant transformer includes a capacitor connected in series with the primary winding between the impulse generator and the elevated terminal.

12. The power receiver of claim **1** wherein comprise multiple resonant transformers having primary windings connected in parallel between the ground terminal and the elevated terminal.

13. The power receiver of claim **12** wherein the resonant transformers have different resonant frequencies.

14. The power receiver of claim **13** wherein the resonant frequencies of the resonant transformers are all below 200 Hz.

15. The power receiver of claim **12** wherein the resonant frequencies of the resonant transformers are matched to respective Schumann resonances.

16. A power receiver for extracting electrical energy from the earth's electric field, said power receiver comprising:

a resonant circuit connected to a ground terminal disposed below the surface of the earth, said resonant circuit having a resonant frequency below 200 Hertz

an impulse generator for generating and applying a high voltage electrical impulse to the resonant circuit to induce current flow from the ground terminal through the resonant circuit; and

a power conversion circuit connected to the resonant circuit to convert electrical current flowing through the resonant circuit to a desired form.

17. The power receiver of claim **16** wherein the impulse generator comprises:

a pulse generator for generating low voltage pulses;

a step-up transformer for converting the low voltage pulses provided by the pulse generator to high voltage impulses;

a spark gap connected between the step-up transformer and resonant circuit to generate a spark responsive to the high voltage impulses from the step-up transformer.

18. The power receiver of claim **16** wherein the impulse generator comprises:

a pulse generator for generating low voltage pulses;

a step-up transformer connected to the resonant circuit for converting the low voltage pulses provided by the pulse generator to high voltage impulses.

19. The power receiver of claim **16** wherein the resonant circuit comprises a resonant transformer having a primary winding, a secondary winding, and resonant capacitor connected in parallel with the primary winding.

20. The power receiver of claim **16** wherein the resonant circuit comprises a resonant transformer having a primary winding, a secondary winding, and resonant capacitor connected in series with the primary winding.

21. The power receiver of claim **16** wherein the resonant circuit comprises multiple resonant transformers having primary windings connected in parallel to the ground terminal.

22. The power receiver of claim **21** wherein the resonant transformers have different resonant frequencies.

23. The power receiver of claim **22** wherein the resonant frequencies of the resonant transformers are all below 200 Hz.

24. The power receiver of claim **23** wherein the resonant frequencies of the resonant transformers are matched to respective Schumann resonances.

25. A ground terminal for a power receiver, said ground terminal comprising:

a ground shaft configured for insertion beneath the surface of the earth;

a hollow cylinder surrounding the ground shaft and having a plurality of openings; and a plurality of ground wires connected at one end to the ground shaft said ground wires being wound around the ground shaft and having free ends protruding through respective openings in the hollow shaft r so that rotation of the ground shaft relative to the hollow cylinder causes the ground wires to extend radially into the earth.

26. A method of extracting power from the earth, said method comprising:

applying a high voltage impulse to resonant circuit coupled to a ground terminal disposed beneath the surface of the earth to initiate resonance in the resonant circuit and induce the flow of current from the ground terminal to the resonant circuit; and

converting the current flowing from the ground terminal into the resonant circuit into a useful form.

27. The method of claim **26** wherein resonant circuit comprises a resonant transformer including a primary winding coupled to the ground terminal and a second winding couple to a power converter, and wherein applying a high voltage impulse to resonant circuit comprises applying a high voltage impulse to the primary winding of the resonant transformer.

28. The method of claim **27** wherein applying a high voltage impulse to the primary winding of the resonant transformer comprises applying an impulse in the range to 10,000 to 40,000 volts to primary winding of the transformer.

(57) ABSTRACT

A resonant transformer connected between a ground terminal and elevated terminal draws current from the earth's electric field through a primary winding of the transformer. An impulse generator applies a high voltage impulse to the primary winding of the resonant transformer to cause current to flow from the ground terminal through the primary winding. The flow of current through the primary winding of the resonant transformer induces a current in the secondary winding, which may be converted and filtered to a usable form, e.g. 60 Hz AC or DC.

POWER RECEIVER FOR EXTRACTING POWER FROM ELECTRIC FIELD ENERGY IN THE EARTH

[0001] This application is a continuation of prior U.S. application Ser. No. 15/397,281 filed Jan. 3, 2017, which is a continuation-in-part of prior U.S. application Ser. No. 14/509,772 filed Oct. 8, 2014, U.S. Pat. No. 9,564,268, which claims the benefit of U.S. Provisional Application No. 61/889,894 filed Oct. 11, 2013, the disclosures of all of which are incorporated by reference herein in their entirety.

TECHNICAL FIELD

[0002] The present invention relates generally to renewable energy, and more particularly to methods and apparatus for extracting energy from subsurface electrical fields beneath the earth's surface.

BACKGROUND

[0003] The earth and the ionosphere cavity may be viewed as a global electric circuit. Electrical currents are constantly flowing within the earth and its atmosphere. Within the earth, the majority of the earth's energy is carried by extremely low frequency (ELF) and ultralow frequency (ULF) waves in the 0-200 Hz frequency range. The earth's rotating magnetic field and positive lightning are two energy sources that sustain the ELF/ULF waves within the earth and the atmosphere.

[0004] A great deal of research has been devoted to studying the electric field present in the earth's ionosphere cavity. Joseph M. Crawley, the "Fair Weather Atmosphere as a Power Source", Proceedings ESA Annual Meeting on Electrostatics 2011; O. Jefimenko, "Operation of Electric Motors from Atmospheric Electric Field," American Journal of Physics, Vol. 39, Pgs. 776-779, 1971; M. L. Breuer, "Usability of Tapping Atmospheric Charge as a Power Source," Renewable Energy, Vol. 28, Pgs. 1121-1127, 2003. Numerous attempts have been made in the past to extract electrical energy from the earth's atmosphere. For example, U.S. Pat. No. 1,540,998 to Plauson describes a system for converting atmospheric electrical energy into usable power. These past attempts have been successful in producing only small amounts of power from the electrical field in the earth's ionosphere cavity. The modest success of these experiments compared to results from other renewable energy sources, such as solar and wind, has tempered further research and prevented widespread use of the electric field in the ionosphere cavity as an energy source.

SUMMARY

[0005] The present invention relates to a power receiver for extracting power from electric fields beneath the earth's surface. In embodiments of the present disclosure, a resonant transformer connected to a ground terminal draws current from the earth's electric field through the primary winding of the transformer. Current flow through the resonant transformer is induced by applying a high voltage impulse to the primary winding. The flow of current through the primary winding of the resonant transformer induces a current in the secondary winding, which may be converted and filtered to a usable form, e.g. 60 Hz AC or DC.

[0006] In some embodiments of the power receiver, the resonant frequency of the resonant transformers is below 200 Hz.

[0007] In some embodiments of the power receiver, the resonant transformer comprises a ferro-resonant transformer.

[0008] In some embodiments, the power receiver further comprises an elevated terminal.

[0009] In some embodiments of the power receiver, the primary winding of the resonant transformer is connected between the ground terminal and elevated terminal.

[0010] In some embodiments of the power receiver, the elevated terminal comprises an upper capacitive plate coupled to the earth's ionosphere cavity.

[0011] In some embodiments of the power receiver, the impulse generator comprises the upper capacitive plate and a spark gap connected between the upper capacitive plate and the primary winding of the resonant transformer. The spark gap comprises a pair of electrodes separated by a gap and configured to generate a spark when a voltage difference between the electrodes reaches a predetermined level.

[0012] In some embodiments of the power receiver, the impulse generator comprises a pulse generator for generating low voltage pulses, a step-up transformer for converting the low voltage pulses provided by the pulse generator to high voltage impulses, and a spark gap connected between the step-up transformer and the primary winding of the resonant transformer to generate a spark responsive to the high voltage impulses from the step-up transformer.

[0013] In some embodiments of the power receiver, the impulse generator comprises a pulse generator for generating low voltage pulses, and a step-up transformer connected to the primary winding of the resonant transformer for converting the low voltage pulses provided by the pulse generator to high voltage impulses.

[0014] In some embodiments of the power receiver, the impulse generator comprises a solid state spark generator.

[0015] In some embodiments of the power receiver, the resonant transformer includes a capacitor connected in parallel with the primary winding.

[0016] In some embodiments of the power receiver, the resonant transformer includes a capacitor connected in series with the primary winding between the impulse generator and the elevated terminal.

[0017] In some embodiments, the power receiver comprises multiple resonant transformers having primary windings connected in parallel between the ground terminal and the elevated terminal.

[0018] In some embodiments of the power receiver, the resonant transformers have different resonant frequencies.

[0019] In some embodiments of the power receiver, the resonant frequencies of the resonant transformers are all below 200 Hz.

[0020] In some embodiments of the power receiver, the resonant frequencies of the resonant transformers are matched to respective Schumann resonances.

[0021] Another embodiment of the power receiver comprises a resonant circuit connected to a ground terminal disposed below the surface of the earth, an impulse generator for generating and applying a high voltage electrical impulse to the resonant circuit to induce current flow from the ground terminal through the resonant circuit, and a power conversion circuit connected to the resonant circuit to convert electrical current flowing through the resonant circuit to a desired form. The resonant circuit has a resonant frequency below 200 Hertz.

[0022] In some embodiments of the power receiver, the resonant circuit comprises a resonant transformer having a primary winding, a secondary winding, and resonant capacitor connected in series with the primary winding.

[0023] In some embodiments of the power receiver, the resonant circuit comprises multiple resonant transformers having primary windings connected in parallel to the ground terminal.

[0024] In some embodiments of the power receiver, the resonant transformers have different resonant frequencies.

[0025] In some embodiments of the power receiver, the resonant frequencies of the resonant transformers are all below 200 Hz.

[0026] In some embodiments of the power receiver, the resonant frequencies of the resonant transformers are matched to respective Schumann resonances.

[0027] Other embodiments of the disclosure comprise a ground terminal for a power receiver. In one embodiment, the ground terminal comprises a ground shaft configured for insertion beneath the surface of the earth, a hollow cylinder surrounding the ground shaft and having a plurality of openings, and a plurality of ground wires connected at one end to the ground shaft. The ground wires are wound around the ground shaft and have free ends protruding through respective openings in the hollow shaft so that rotation of the ground shaft relative to the hollow cylinder causes the ground wires to extend radially into the earth.

[0028] Other embodiments of the disclosure comprise methods of extracting power from the earth. In one embodiment, the method comprises applying a high voltage impulse to resonant circuit coupled to a ground terminal disposed beneath the surface of the earth to initiate resonance in the resonant circuit and induce the flow of current from the ground terminal to the resonant circuit, and converting the current flowing from the ground terminal into the resonant circuit into a useful form.

[0029] In some embodiments of the method, the resonant circuit comprises a resonant transformer including a primary winding coupled to the ground terminal and a second winding coupled to a power converter, and applying a high voltage impulse to resonant circuit comprises applying a high voltage impulse to the primary winding of the resonant transformer.

[0030] In some embodiments of the method, applying a high voltage impulse to the primary winding of the resonant transformer comprises applying an impulse in the range to 10,000 to 40,000 volts to primary winding of the transformer.

BRIEF DESCRIPTION OF THE DRAWINGS

DETAILED DESCRIPTION

[0042] Referring now to the drawings, a power receiver for extracting energy from the earth's electric field are illustrated and indicated generally by the numeral 10. Various embodiments of the power receiver **10** are described and similar reference numbers are used throughout the description to indicate similar components.

[0043] The power receiver **10** converts energy in the ELF/ULF waves to useful form, e.g. 60 Hz AC or DC. The power receiver **10** is essentially a resonance circuit that resonates at the natural resonance frequencies in the earth's electric field. These resonance frequencies, known as Schumann resonance frequencies, occur at 7.83 Hz, 14.3 Hz, 20.8 Hz, 27.3 Hz, and 33.8 Hz. A high voltage impulse initiates resonance within the power receiver **10**. In the resonant mode, the impedance of the power receiver **10** is reduced to near zero thus inducing ground currents to flow into the power receiver **10** where the ground currents are converted to useful form.

[0044] FIG. **1** illustrates a first embodiment of the power receiver **10**. The power receiver **10** comprises a resonant transformer **30** connected between an elevated terminal **15** and ground terminal **25**. In this embodiment, the elevated terminal **15** is capacitively coupled to electric fields within the earth's ionosphere cavity and functions as an upper capacitive plate. A lower capacitive plate **20** is connected to the ground terminal **25** beneath the surface of the earth.

[0045] The resonant transformer **30** comprises a primary winding **35**, secondary winding **40**, ferromagnetic core **45**, and capacitor **50**. One end of the primary winding **35** is connected to the lower capacitive plate **20** and ground terminal **25**. The opposite end of the primary winding **35** is connected via a spark gap **90** to the elevated terminal **15**. The capacitor **50** is connected in parallel with the primary winding **35** of the resonant transformer **30** to form an LC circuit **55** with a resonance frequency range of between about 0.1 and 200 Hz. In a preferred embodiment, the resonant transformer has a Q of about 10 or greater and resonance frequency in the range of about 0.1 -200 Hertz. For example, the resonant transformer **30** may have a resonance frequency of about 7.83 Hz, the fundamental Schumann resonance frequency. The secondary winding **40** of the resonant transformer **30** is connected to a power converter **110** as will be hereinafter described in greater detail. The power converter **110** converts the energy extracted from the earth's electric field by the power receiver **10** into a usable form for driving a load **140**.

[0046] The elevated terminal/upper capacitive plate **15** comprises an insulated, dish-shaped plate with a large radius of curvature. The capacitance and resistance of the elevated terminal is chosen for receiving broadband electric field frequencies in the 0-200 Hz range. The upper capacitive plate **15** is sized to maximize to the extent practical coupling with the electric field in the earth's ionosphere cavity.

[0047] The lower capacitive plate **20** is also a dish-shaped plate with a large radius of curvature. One function of the lower capacitive plate **20** is to collect charge from the earth's ground currents and provide an instantaneous source of current as hereinafter described. The capacitance and resistance of the lower capacitive plate **20** is selected to promote the flow of current from the ground with minimal losses.

[0048] The spark gap **90** connected between the elevated terminal **15** and resonant transformer **30** comprises a pair of electrodes **95**, **100** separated by an evacuated air gap **105**. Electrode **95** is connected to the upper capacitive plate **15**. Electrode **100** is connected to the resonant transformer **30**. The spark gap **105** prevents electrical discharge from the upper capacitive plate **15** to the earth's ionosphere cavity. The spark gap **90** in combination with the elevated terminal **15** function as an impulse generator that applies a high voltage impulse of about 10,000-40,000 volts to the primary winding **35** to initiate resonance in the transformer **30**.

[0049] In operation, the capacitive coupling of the upper capacitive plate **15** induces a high voltage operating current in the upper capacitive plate **15**. The upper capacitive plate is connected to a first electrode **95** to the spark gap **90**. When the voltage difference between the electrodes **95** and **100** reaches a threshold, a spark forms across the electrodes **95**,**100** and a high voltage impulse is applied to the primary winding **35** of the resonant transformer **30**. This high voltage impulse initiates resonance within the transformer **30**.

[0050] In resonant mode, the impedance of the resonance transformer is reduced to nearly zero allowing current to flow from the capacitive plate **20** and ground terminal **25** through the primary winding **35** of the transformer **30**, which in turn induces current in the secondary winding **40**. Power converter **110** converts the current flowing through the secondary winding **40** into a usable form for driving a load **140**. The transformer **30** will continue to resonate for a short period of time. By providing high voltage impulses to the primary winding **35** of the resonant transformer **30** at periodic intervals, it is possible to maintain a continuous flow of current from the earth into the resonant transformer **30**, thus producing a continuous supply of power.

[0051] FIG. **2** discloses a second embodiment of the primary receiver **10**. This embodiment includes a resonant transformer **30** connected between an elevated terminal **15** and ground terminal **25**. The resonant transformer **30** comprises a primary winding **35**, secondary winding **40**, ferromagnetic core **45** and a high voltage capacitor **50**. One end of the primary winding **35** is connected to the ground terminal **25**. The opposite end of the primary winding **35** is connected to the elevated terminal **15**. The capacitor **50** has a capacitance of about 0.01 micro-farads. In contrast to the previous embodiment, capacitor **50** is connected in series with the primary winding **35** and elevated terminal **15** and forms a LC circuit **55** with a Q of about 10 or greater and a resonance frequency in the range of about 0.1 to 200 Hz. In a preferred embodiment, the resonance frequency of the transformer **30** is 7.83 Hz, the fundamental Schumann resonance frequency. An impulse generator **60** is connected between the primary winding **35** of the resonant transformer **30** and the series capacitor **50** and applies a high voltage impulse to the primary winding **35** of the resonant transformer **30**. A battery **130** or other external power source supplies power to the impulse generator **60**. As previously described, the high voltage impulse applied by the impulse generator **60** initiates resonance within the resonant transformer **30** inducing current flow from the ground terminal **25** into the primary winding **35** of the resonant transformer **30**. The flow of current from the ground terminal **25** through the primary winding **35** induces current in the secondary winding **40**. Power converter **110** converts the electrical energy in the current flowing through the primary winding **40** into a usable form.

[0052] In contrast to the first embodiment, it is not required to capacitively couple the elevated terminal **15** in the second embodiment to the earth's ionosphere cavity. Rather, the elevated terminal **15** in this embodiment provides lightning protection and dissipates some of the energy flowing into the power receiver **10** to the earth's ionosphere cavity. Also, in contrast to the first embodiment, the capacitor **50** is connected in series between the primary winding **35** of the transformer **30** and the elevated terminal **15**. Those skilled in the art will appreciate that the capacitor **50** could also be connected in parallel rather than series with the primary winding **35** as shown in FIG. **1**. Another difference is that the impulse generator **60** has an external power source. The amount of energy generated by the power receiver **10**, however, is far greater than the energy needed to generate high voltage impulses. The first embodiment does not require an external power source to generate high voltage impulses.

[0053] FIG. **3** illustrates a third embodiment of the power receiver **10**. This embodiment is essentially the same as the embodiment shown in FIG. **2**. The main difference is that a center tap of the primary winding **35** in the resonant transformer **30** is connected to an electrical ground **85**. It should be appreciated that the electrical ground **85** may be different than the earth ground. When the center tap of the resonant transformer **30** is grounded at a distance away from the ground terminal **25** (e.g. 50 ft to 100 ft), the power receiver **10** becomes a transmitter via the ground loop formed.

[0054] FIG. **4** illustrates the power receiver **10** of FIG. **2** in greater detail. The power receiver includes a resonant transformer **30** connected between a ground terminal **25** and an elevated terminal **15**. The ground terminal **25** may comprise a ⅝-inch×8-foot copper ground rod, such as the ERICO 615880UPC. The elevated terminal **15** may comprise a 90% copper mesh formed into a hemisphere with a radius of about 9 inches. The elevated terminal **15** may be elevated at a height of approximately 6 feet above the ground.

[0055] The resonant transformer **30** includes a primary winding **35**, secondary winding **40**, ferromagnetic core **45** and series capacitor **50** configured as previously described. The resonant transformer **30** may have a Q of about 10 and a resonance frequency in the range of about 0.1 to 200 Hz. The resonant transformer **30** may be made using an Allanson transformer (part #1530BP120R) connected in series with a 0.01 micro-farad capacitor, such as the Condensor Products high voltage capacitor (part #TC 103-17-125). The resonant transformer **30** is used in a step-down configuration. The center tap of the resonant transformer **30** may optionally be connected to a ground.

[0056] An impulse generator **60** is connected between the primary winding **35** of the resonant transformer **30** and the series capacitor **50** and applies a high voltage impulse in the range of about 10,000 to 40,000 volts to the primary winding of the transformer **30**. A battery **130** or other external power source supplies power to the impulse generator **60**. The power converter **110** connects to the secondary winding **40** of the resonant transformer **30** for converting current in the secondary winding of the transformer to a useful form.

[0057] The impulse generator **60** comprises a pulse generator **65** for generating low voltage pulses, a step-up transformer **80** for converting the low voltage pulses from the pulse generator **65** to high voltage pulses, and a spark gap **90** for generating sparks responsive to the high voltage pulses from the step-up transformer **80**.

[0058] The pulse generator **65** comprises a square wave generator **70**, such as a Sinometer VC2002 function signal generator, and solid state relay **75**. The square wave generator **70** generates a digital pulse stream. In one embodiment, the digital pulse stream generates a square waveform with a frequency of about 7.83 Hz. The frequency of the digital pulse stream is selected to match the resonance frequency of the transformer **30**, though such is not necessarily required. The pulse stream output from the square wave generator **70** is applied to the solid state relay **75**. The solid state relay **75** is connected between a battery or other power source and a first winding of the step-up transformer **80**. The battery may comprise a 12 V, 7.0 A/H sealed lead acid battery, such as the ELB 1270A by Lithonia Lighting. The solid state relay **75** functions as a switch that is activated responsive to the waveform from the square wave generator **70** to provide a continuous stream of low voltage pulses from the battery to the first winding of the step-up transformer **80**. A 1 ohm resistor is connected between the solid state relay **75** and step-up transformer **80**.

[0059] The step-up transformer **80** may comprise a Transco 15 kV, 30 mA neon sign transformer (part # S15612). The step-up transformer **80** converts the low voltage pulses from the pulse generator **65** to high voltage pulses that are applied to the spark gap **90**. The step-up transformer has a 0.5 micro-farad capacitor connected in parallel with the primary winding of the step-up transformer **80**. The step-up transformer produces pulses at the output of about 30,000 to 40,000 volts.

[0060] The spark gap **90** comprises a pair of electrodes **95**, **100** separated by an air gap **105**. A suitable spark gap electrode pair is the Information Unlimited SPARK05 ¼-inch×1-inch tungsten electrodes. As previously described, when the voltage potential between the electrodes **95**, **100** reaches a threshold, a spark forms between the electrodes **95**, **100** and supplies a nearly instantaneous, high voltage impulse to the primary winding **35** of the resonant transformer **30**. This high voltage impulse initiates resonance in the resonant transformer **30** inducing current flow from the ground terminal **25** through the primary winding **35** of the resonant transformer **30**.

[0061] The power converter **110** comprises a bridge rectifier **115**, filter capacitor **120**, charge controller **125**, and inverter **135**. A suitable rectifier is the Micro Commercial Components 10 amp, 1000 volt bridge rectifier (Part #GBJL 1010). The bridge rectifier **115** converts the AC current flowing through the secondary winding **40** of the resonant transformer to a DC current. A filter capacitor **120** removes unwanted frequencies from the DC current. A suitable capacitor **120** is Cornell Dubilier 1000 uF 450 VDC capacitor (part #383LX102M450N082). The filter capacitor **120** has a capacitance of about 1000 micro-farads. The DC current is input to the charge controller **125**. The charge controller **125** may, for example, comprise a maximum power point tracking (MPPT) charge controller, such as a Tracer 4215 BN MPPT Solar Charge Controller, which is commonly used in solar power generating systems. The charge controller **125** applies a small amount of energy to a battery **30** to charge the battery **130**. As previously noted, the battery **130** serves as a power source for the impulse generator **60**. The remaining current is supplied to an inverter **135**, which converts the DC current to an AC current with a desired voltage and frequency, e.g., 120 volts/60 Hz AC. A suitable inverter **135** is the 1500 W Pure Sine power inverter (AIMS) (part # PWRI1500125). The power converter **110** as shown in FIG. **4** may be utilized in the embodiment shown in FIGS. **1**, **2** and **3**.

[0062] FIG. **5** illustrates a power receiver **10** according to another embodiment. The power receiver **10** comprises a plurality of resonant transformers **30** connected between a ground terminal **25** and elevated terminal **15**. Each of the resonant transformers **30** comprises a primary winding **35**, secondary winding **40**, ferromagnetic core **45** and series capacitor **50**. The primary windings **35** of the resonant transformers **30** are connected in parallel. The secondary windings **40** are connected in series with the power converter **110**. An impulse generator **60** applies a high voltage impulse to the primary windings **35** of the resonant transformers **30**. A battery **130** or other external power source supplies power to the impulse generator **60**. The power converter **110** converts the current in the power converter circuit to a usable form for driving a load **140**.

[0063] In one embodiment, each of the resonant transformers **30** shown in FIG. **5** is configured to have a different resonant frequency. In one embodiment, the resonant transformers **30** are configured to resonate at frequencies of 7.83 Hz, 14.8 Hz, 20.3 Hz and 26.8 Hz respectively. Additional resonant transformers **30** could be added to operate at other resonance frequencies.

[0064] FIGS. **6A-6C** illustrate a high quality ground antenna array **200** which may be used as a ground terminal **25**. The ground antenna array **200** comprises a generally cylindrical ground shaft **205** disposed with a hollow cylinder **220** and a plurality of reinforced, heavy gauge ground wires **210** attached at one end to the ground shaft **205**. The ground shaft **205** and ground wires **210** should be highly conductive and have low resistance to supply current from the ground to the power receiver **10**. In one embodiment, the ground wires **210** may be copper or other highly-conductive metal. The end of the ground shaft may be pointed to facilitate insertion into the earth. A connection port on the ground shaft **220** is provided to electrically connect the ground antenna array **220** to the resonant transformer **30**.

[0065] The hollow cylinder **220** has external threads **25** to facilitate insertion into the ground. A rotator nut **235** is fixedly secured to the top end of the hollow shaft **220**. A square shaft **215** protrudes from the top end of the ground shaft **205** into the opening in the rotator nut **235**. FIG. **6B**. A tool **250**, shown in FIG. **7**, engages with the rotator nut **235** and square shaft **215** during insertion of the ground antennas array **200** into the ground as will be hereinafter described.

[0066] The insertion tool **250** is shown in FIG. **7**. The insertion tool **250** includes a tool body **255** having a first socket **260** on one side to fit the rotator nut **235** on the hollow cylinder **220** and a second socket **265** on the other side to fit the square shaft **215** on the ground shaft **205**. Arms **270**

extend from the outer periphery of the tool body **255** for manually or mechanically turning the insertion tool **250**.

[0067] Before the antenna array **200** is deployed, the ground wires **210** are wound around the ground shaft **205** with the free ends protruding slightly from respective openings **230** in the hollow cylinder **220** to a distance not to exceed one half (½) the depth of the external threads **225** on the hollow cylinder **220**. FIG. **6**B illustrates the ground antenna array **200** before deployment. FIG. **6**C illustrates the ground antenna array in a deployed configuration.

[0068] Installation of the ground antenna array **200** is performed in two stages. In the first stage, a hole slightly smaller in diameter than the threads **235** of the hollow cylinder **220** is drilled into the Earth to a depth matching the length of the hollow cylinder **220** or slightly longer. The hole is filled with water and the water is allowed to soak into the soil. After the ground is softened, the hollow cylinder **220** is rotated using the insertion tool **250** to insert the ground antenna array **200** into the ground. The first socket **260** of the insertion tool **250** is engaged with the rotator nut **230** and the insertion tool **250** is turned by hand or a mechanized rotating shaft fitted and attached to the tool arms **270** to thread the ground assembly into the hole. During the initial insertion of the ground antenna array **200**, the ground shaft **205** is fixed to the hollow shaft **220** and rotates with the hollow shaft. The hollow cylinder **220** is rotated until it reaches the full depth of the hole.

[0069] Once the ground antenna array **200** has been fully inserted into the earth, the insertion tool **250** is flipped over and the second socket **265** of the insertion tool **250** is engaged with the square shaft **215**. The insertion tool **250** is turned by hand or a mechanized rotating shaft fitted and attached to the tool arms **270** to rotate the ground shaft **205**. During the second phase, the ground shaft **205** rotates freely inside the hollow cylinder **220**. Rotation of the ground shaft **205** causes the reinforced ground wires **210** to extend radially into the earth. The ground shaft **220** is rotated until the ground wires are fully extended. The ends of the ground wires may be sharpened to aid in the extension of the ground wires during the second phase.

[0070] After the ground antenna array **200** is deployed, a connection cable **280** is attached to a connection port **240** on the ground shaft **220** to electrically connect the ground antenna array **220** to the resonant transformer **30** in the power receiver **10**.

What is claimed is:

1. A power receiver for extracting electrical energy from the earth's electric field, said power receiver comprising:

a resonant transformer connected to a ground terminal disposed below the surface of the earth;

an impulse generator for generating and applying a high voltage electrical impulse to a primary winding of the resonant transformer to induce current flow from the ground terminal through the primary winding of the transformer; and

a power converter connected to a secondary winding of the resonant transformer to convert an alternating current flowing through the secondary winding to a direct current.

2. The power receiver of claim **1** wherein a resonant frequency of the resonant transformers is below 200 Hz.

3. The power receiver of claim **1** wherein the resonant transformer comprises a ferro-resonant transformer.

4. The power receiver of claim **1** wherein the impulse generator comprises:

a pulse generator for generating low voltage pulses;

a step-up transformer for converting the low voltage pulses provided by the pulse generator to high voltage impulses;

a spark gap connected between the step-up transformer and the primary winding of the resonant transformer to generate a spark responsive to the high voltage impulses from the step-up transformer.

5. The power receiver of claim **1** wherein the impulse generator comprises a solid state spark generator.

6. The power receiver of claim **1** wherein said resonant transformer includes a capacitor connected in parallel with the primary winding.

7. The power receiver of claim **1** wherein said resonant transformer includes a capacitor connected in series with the primary winding.

8. A method of extracting electrical energy from the earth's electric field, the method comprising:

applying a high voltage electrical impulse to a primary winding of a resonant transformer connected to a ground terminal disposed below the surface of the earth to induce current flow from the ground terminal through the primary winding of the transformer; and

converting an alternating current flowing through a secondary winding of the resonant transformer to a direct current.

9. The method of claim **8** wherein a resonant frequency of the resonant transformers is below 200 Hz.

10. The method of claim **8** wherein the resonant transformer comprises a ferro-resonant transformer.

11. The method of claim **8** wherein the impulse generator comprises:

a pulse generator for generating low voltage pulses;

a step-up transformer for converting the low voltage pulses provided by the pulse generator to high voltage impulses;

a spark gap connected between the step-up transformer and the primary winding of the resonant transformer to generate a spark responsive to the high voltage impulses from the step-up transformer.

12. The method of claim **8** wherein the impulse generator comprises a solid state spark generator.

13. The method of claim **8** wherein said resonant transformer includes a capacitor connected in parallel with the primary winding.

14. The method of claim **8** wherein said resonant transformer includes a capacitor connected in series with the primary winding.

Diodes

Back to the index

Which diode can I use best in my crystal receiver?

Maybe you think a diode with a voltage drop as low as possible, then also small signals at the detector circuit are detected.
But diodes with a low voltage drop, also have a high reverse current (leaking current), this will load the detector circuit heavier, the Q of the detector circuit reduces, and with that also the voltage across the LC circuit.
At a lower input voltage the diode will give much more losses, and it can happen that despite the lower voltage drop of the diode, you have less voltage at the load resistor.
Besides that, reduction of circuit Q will also gives a less selective receiver.

For every 20 mV less voltage drop, the reverse current will approximately double.

Germanium, silicon, en schottky diodes.

Depending on the material they are made from, we can distinguish germanium diodes, silicon diodes and schottky diodes.
There are some more types, which are not discussed here.

Silicon diodes have the highest voltage drop (about 0.5 Volt) and are for this reason not very useable for crystal receivers.
Unless we use a small DC bias current, which brings the diode already a little bit in conduction.

Germanium diodes have a low voltage drop (about 0.1 - 0.2 Volt) and are often used in crystal receivers.
The properties like voltage drop and reverse current can vary a lot between two germanium diodes of the same type.
In practice we can best test several germanium diodes in our receiver and then choose the best.
The diode resistance RD of germanium diodes is most times rather low, and only useable in crystal receivers with a low Q (low sensitivity and low selectivity).
For high performance receivers, we can better use a suitable schottky diode.

Schottky diodes have a voltage drop of about 0.25 Volt.
The differences in properties between two diodes of the same type are often small.
Schottky diodes with the correct resistance RD are very useable in high quality crystal receivers.

The given voltage drop is normally measured at a forward current of about 1 mA.
Also if we measure the voltage drop of a diode with a multimeter, the test current shall be about 1 mA.
But also below this voltage drop the diode can conduct current, and can rectify a RF (radio frequency) signal.
Only the current through the diode is then much smaller.
When receiving very weak stations, the current through the diode can be e.g. only 10 nA.
At such a low current, the voltage drop of the diode is also much lower then at 1 mA.

Detected voltage as function of the input voltage

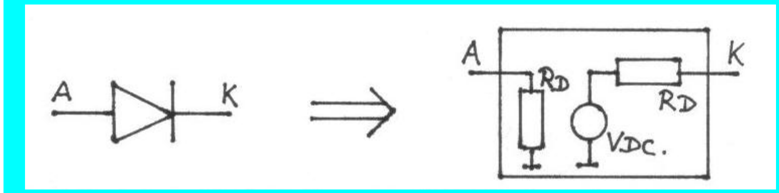
If we rectify a RF signal with a diode we can distinguish two situations.

Situation 1: Rectifying in the linear region
If the input voltage is high enough (well above the voltage drop of the diode at 1 mA), the output voltage of the diode will be about proportional to the input voltage.
So double input voltage, gives about double output voltage.

The output voltage is almost equal to the peak value of the input voltage.
The power losses in the diode are in this region very low compared to the rectified power.

Situation 2: Recifying in the square law region
If the input voltage is low, lower then the voltage drop of the diode (at 1 mA) then the situation is completely different.
The input of the diode behaves for the RF signal like a resistor with value RD.
The output of the diode behaves like a DC voltage source in series with a resistor, the value of this resistor is also equal to RD.
The value of the DC voltage source is square law related to the amplitude of the RF input signal.
So double input voltage, gives 4 times as much detected DC voltage at the output
In the square law region the output voltage of the diode will be much lower then the input voltage, the diode gives much power loss between input and output.
The lower the input voltage, the higher the losses.
The higher the input voltage, the lower the diode losses.
When further increasing the diode input voltage, we gradually come into the linear detection region.
When receiving weak stations, detection takes place in the square law region.

Between the linear and square law region, there is a region not linear, and not square law but somewhere in between.
This region is not discussed here.



Equivalent circuit of a diode at low input voltages.

Via this link you find a measurement on several schottky diodes, which shows detection in the square law region takes place at input voltages below 200 mVpp.

Diode resistance RD.

At zero voltage, diodes have a certain resistance.
This resistance at zero Volt we call RD.
The lower the reverse leaking current of the diode, the higher resistance RD.
When detecting small signals (in the square law region) the input of the diode also behaves like a resistor with value RD.

But how do we know the RD of a diode?
We can calculate it with the formula:
formula 1: **RD = 0.000086171 x n x TK / Is**

RD = diode resistance at zero Volt (unit: Ohm)
n = *ideality factor*, the lower this factor the better, between 1.0 and 1.1 is a very good value.
TK = temperature in Kelvin (= temperature in ºC + 273)
Is = *saturation current* (unit: A)
x = multiply

The values of n and Is can (sometimes) be found in the diode datasheet.

In the following table some types of schottky diodes, with the values for n, Is and Rd, the maximum reverse voltage and the diode capacitance at zero voltage.

type diode	n	Is at 25 ºC	RD at 25 ºC	maximum reverse voltage	capacitance	
5082-2835	1.08	22 nA	1260 kΩ	8 Volt	1 pF	datasheet
BAT85	?	?	± 200 kΩ ??	30 Volt	10 pF	datasheet
HSMS 2820	1.08	22 nA	1260 kΩ	15 Volt	1 pF	datasheet
HSMS 2850	1.06	3000 nA	9.07 kΩ	2 Volt	0.3 pF	datasheet
HSMS 2860	1.10	38 nA	743 kΩ	4 Volt	0.3 pF	datasheet

To decrease the value RD, we can connect more diodes in parallel, with two the same diodes parallel the value of RD shall halve.
With 3 diodes parallel, the value of RD shall be divided by 3 etc..

Diode resistance when using bias current.

We can decrease the value of RD by sending a small DC bias current (e.g. 0.1 uA) in forward direction through the diode.
The higher the bias current, the lower RD will be.
With the following formula we can calculate the diode resistance RD, when we make use of a DC bias current.

Formula 2: **RD = 0.000086171 x n x TK /(Ib + Is)**

RD= diode resistance at certain DC bias current Ib (unit: Ohm)
n= *ideality factor* of the diode
TK = Temperature in Kelvin (= temperature in ºC + 273)
Ib= DC bias current through the diode in A
Is =*saturation current* of the diode in A

A diode with a certain RD value at a certain bias current, gives the same receiving performance as a diode without bias current with the same RD.

Influence of temperature on "saturation current: Is"

The saturation current (Is-value) is strongly depending on temperature.
A temperature increase of 1 ºC will increase the Is value by about 7 %.
In datasheets, the Is value is most times given at 25 ºC.
If the diode temperature is not 25 ºC, but another value "T", then we must multiply Is with a factor 1.07^(T-25).
T = diode temperature
^ = raise to the power of

Ideality factor n

The ideality factor n of a diode indicates how good the diode performs with regard to an ideal diode.
A (not existing) ideal diode has a value of n=1.
At low input signals, the maximum available detected output power is proportional to 1/n.
So doubling the n will halve the output power (this only applies at weak signals).

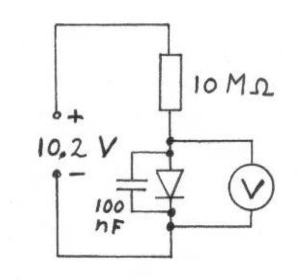
Diode capacitance

Between the two connections of the diode there will be a certain capacitance (capacitor value), when this capacitance is fairly high (e.g. 10 pF) the tuning range at high frequencies is limited.

At increasing reverse voltage across the diode the capacitance will reduce, also the detected voltage in a crystal receiver is such a reverse voltage.
Through this, the frequency of the circuit can shift upwards when receiving strong signals.
On the next page: experiments with a detector unit you find in table 3 a measurement about the frequency shift.

Measuring the Is value of a diode.

We can measure the Is value of a diode as follows:
Send a small current through the diode, the value of this current (ID) must be about 1 µA.
Measure the voltage across the diode (VD).



Circuit diagram for measuring the Is value of a diode.
The voltage across the diode is about 0.2 Volt.
The voltage across the resistor is about 10 Volts, so the current is about 1 µA.

The voltmeter must have a resistance of at least 10 MΩ.
The 100 nF capacitor reduces the influence of radio signals and hum on the measurement.

Calculate Is with the formula:

formula 3: **Is = ID / (e^ (VD /(0.0257xn))-1)**

Is = *saturation current* of the diode in nA
ID = current through the diode in nA, (1 µA = 1000 nA)
e = base of the natural logarithms, this is about 2.718
^ = raise to the power of
VD = voltage across the diode in Volt
n = *ideality factor* of the diode, if you don't know this value, take for instance: n= 1.08

More information about measuring the Is you can find on the website of Ben Tongue , in his articles number 4 and 16.

I measured the Is value of several diodes, and calculated the diode resistance RD.
Also some European germanium types are measured.
Several diodes are measured of the type OA95 and AA119

Diode	VD (Volt) at 1 µA	Is (nA)	RD (kΩ).
HSMS282K	0.1341	7.9	3428
HSMS282K 2 parallel	0.118	14.5	1867
HSMS286K (1 diode)	0.1116	18.3	1479
5082-2800	0.1871	1.14	23756
5082-2835	0.1464	5.04	5373
5082-2835 2 parallel	0.1289	9.5	2850
BAT 82	0.136	7.3	3710
BAT 85	0.0686	90.8	298
OA81 (germanium)	0.0225	800	34

OA95 #1 (germanium)	0.0272	600	45
OA95 #2	0.0221	821	33
OA95 #3	0.0271	604	45
OA95 #4	0.0304	502	54
AA116 (germanium)	0.0441	256	106
AA119 #1 (germanium)	0.0320	461	59
AA119 #2	0.0363	370	73
AA119 #3	0.0428	272	100

The HSMS282K is the same as the HSMS2820, only the HSMS282K has 2 equal diodes in one package.

The Is value of the HSMS282K, the HSMS286K and the 5082-2835 is lower than the value in the datasheet, this has also been noticed by other people.
Ben Tongue wrote me, that the Is value of the 5082-2835 has been reduced over the years by the manufacturer.
Also temperature has big influence, I measured at 18 ºC, in datasheets the Is value is given at 25 °C.
A increase from 18 °C to 25 °C will increase the Is by 60 %.

[57] ABSTRACT

A defense system wherein a radar intercepts and follows a target and includes an antenna array and a low level source of microwave energy for exciting the elements of the array to produce radar returns and define the path. A microwave storage reservoir is supplied upon demand with high energy microwave energy and is coupled to microwave feed channels leading to the elements of the antenna array. Microwave dump switches at the juncture of the channels and the reservoir control flow of energy from the reservoir. Control means responsive at least in part to the presence of returns periodically actuate the dump switches for flow of microwave energy from the reservoir to the target via the antenna array.

FIG. 5

HIGH ENERGY MICROWAVE DEFENSE SYSTEM

This invention relates to the utilization of high energy electromagnetic waves, and more particularly to a method and system for accumulating and releasing high energy electromagnetic waves in a medium such as the earth's atmosphere.

In national defense, expenditures of time and money are being made in the area of ballistic missiles defenses. One purpose is to provide a defense system specifically directed to destruction of enemy missiles during flight long before a target is reached. The high cost of such systems is occasioned by the necessity of propelling and guiding a physical mass along a path at such speeds as to enable it to collide with or otherwise destroy an enemy missile in flight.

The present invention avoids much of the difficulty encountered in such systems by generating and focusing electromagnetic energy of high intensity to a target to impact the target with electromagnetic energy traveling at the speed of light. Radar systems heretofore have been developed for locating bodies traveling at high speeds through the earth's atmosphere and tracking them. Radars are highly developed and provide reliable information which in an early warning sense heralds the approach of missiles, for example, and provides data to define the path and identify the target point.

The present invention is provided to operate in conjunction with a radar system to generate and store a high quantity of electromagnetic energy and then to dump such energy from storage, feeding the same to an antenna for transmission along the path controlled by the radar. The electromagnetic energy will be focused onto the airborne body with such magnitude as to impart destructive action thereto.

More particularly, in accordance with the present invention, a system is provided for operation of a phased array radar to intercept and follow the path of a body spaced from the radar and includes an antenna array and a source of microwave energy for exciting the array to produce target dependent radar returns.

Further, one or more evacuated microwave storage reservoirs are provided with microwave feed channels leading from the reservoir to elements of the antenna array. Microwave dump switches located at the juncture of the channels and the reservoir permit extraction of energy from the reservoir. Means responsive at least in part to the presence of radar returns actuate the dump switches for flow of microwave energy from the reservoir to the body via the antenna array.

In a further aspect, the invention employs the method of focusing a phased array radar onto a body traveling along a path spaced from the radar, repeatedly storing over substantial intervals microwave energy in a microwave storage reservoir, periodically dumping the energy stored from the radar via channels leading to the array for transmission of high energy microwaves to said body. Microwave energy is fed over a substantial period of time into a reservoir having superconductive walls with windows therein normally coated with a superconductive material which responsive to local heating momentarily become transmissive to the microwave energy stored in the reservoir.

For a more complete understanding of the present invention and for further objects and advantages thereof, reference may now be had to the following description taken in conjunction with the accompanying drawings in which:

FIG. 1 is a schematic representation illustrating operation of the present invention;

FIG. 2 is a schematic sectional view of the reservoir of FIG. 1;

FIG. 3 is a view of a portion of the wall of the reservoir of FIG. 1 illustrating a window therein;

FIG. 4 illustrates a modified form in detail of one of the windows;

FIG. 5 illustrates an embodiment of the invention;

Referring now to FIG. 1, a schematic representation of the invention has been shown wherein a phased array radar antenna **10** is provided on the earth's surface for tracking aircraft or projectiles such as the projectile **11** during flight through the earth's atmosphere at a range of the order of a hundred miles. The antenna **10** is fed by way of channels **12** from a radar control unit **13** which is coupled by way of a tee **14** to the channels **12**. The radar **13** in conjunction with antenna **10** operates in a conventional manner to transmit energy into space and to detect returns reflected from projectile **11**.

The channels **12** also lead to a microwave reservoir which is a resonant sphere **20**. The sphere **20** is connected to a plurality of channels, such as channels **21** and **22**, to the antenna **10** all by way of tees represented by the tee **14**.

The radar unit **13** is also coupled by way of channel **23** to sphere **20**. The radar unit **13** is connected by way of a control channel **24** to laser units **25**. As will later be explained, the channels **21** and **22** leading to the sphere **20** are coupled to the sphere **20** by way of dump switches located at the juncture of sphere **20** and the channels **21** and **22**. The dump switches are actuated by energy transmitted by way of laser beams from the laser **25**. Sphere **20** has superconducting walls maintained at a supercooled condition as by liquid helium circulating in the walls. Laser beams from laser **25** are focused onto windows locally to heat them to cause the microwave energy stored within sphere **20** to be dumped into the channels **12** and thence transmitted by way of radar antenna **10** to impinge the projectile **11**. The microwave energy from the radar antenna **10** travels at the speed of light making it possible to repeatedly impact the projectile **11** during its course of flight. The repetition rate depends upon the rate at which build-up of energy in sphere **20** reaches the necessary level to transmit bursts of electromagnetic energy from antenna **10** which would be destructive of the projectile **11** or parts thereof. Thus, high energy bursts of microwave radiation are directed at target **11** which could be, for instance, an I.C.B.M. warhead, a satellite, a submarine launched ballistic missile or an aircraft. The system also acts, at a much lower power level, as its own acquisition phased array radar system.

The high power system is composed of a multiplicity of megawatt power tubes in radar unit **13** coupled to the large superconducting lined resonant cavity **20**. By providing a high "Q" cavity, only minimal power is required to offset high frequency skin losses. Typically cavity **20** may have a radius of 10 meters with a field level of 1×10^6 volt/cm therein. Stored energy of 1×10^8 joules can be maintained during operative periods. Pure niobium forming the walls of resonator **20** has heretofore similarly been employed in systems in which such field levels were present. Other alloys and materials can operate at even higher levels in which case the system dimensions could be reduced. By applying very rapid rise time ($\approx 1\times10^{-8}$ sec.) heating to local areas of thin film superconducting dump switches the stored energy is coupled via a multiplicity of high pressure inert gas horns into the atmosphere without breakdown. In about 1×10^{-6} seconds the energy is coupled out of resonator **20**. Thus, a pulse of duration 1×10^{-6} to 1×10^{-7} seconds with power of 1×10^{14} to 1×10^{15} watts is generated. Such horns form the integral phased array antenna **10**. The antenna thus excited illuminates with a central energy lobe 2×10^{-4} radians wide when using 3 cm radiation from a 500 foot base. At a 100 mile range, the central lobe has a width of 100 feet. An object with a linear dimension of 5 feet would intercept approximately $(5/100)^2$ or ¼% of the burst of radiated energy. This is $\approx 3\times10^5$ joules which would cause significant damage such as blowing off several grams of vaporized material upon absorption. At the same time, shocks would be generated in the object of as much as 100 kilobars.

A recycle time of one second, and hence a pulse rate of 1/second may be maintained by a power source of 1×10^8 watts. A target moving at 5 miles a second would receive about 200 bursts in 100 miles with shocks of varying strengths. By increasing the amount of power available, a pulse rate of 10 per second is feasible and 200 bursts could impact either on one, or several targets within range.

The effects on a body of high energy bursts are twofold: (1) the shock kill mechanism and (2) the material ablation could reach proportions sufficient to deflect and randomize the impact point sufficiently to make the system inaccurate and useless. If a satellite has a nonmetal absorptive skin in the X-band, minimizing the radar echo cross section, such a skin would ideally absorb most of the burst energy, ablating from 100 gms/burst at a 100 mile range to 10 Kg/burst at a 10 mile range. This may reduce the shock strength into the 10 Kilobar range, but would cause sufficient ablative damage and orbital error to cause a large random miss-distance which could be from 2 to 10 miles for a one ton object.

Normally power is required only to operate low energy radar search and acquisition and to run the vacuum pumps to maintain the main resonator liquid helium bath temperature and void gas dump dewar temperature. During an emergency such as an I.C.B.M. attack, about 2×10^8 watts per site is required. This requirement may only last, at a given site, for a few minutes. The power is used to fill the resonator from beam power tubes. The resonator with niobium walls at liquid helium temperatures has "Q's" of the order of 1×10^{11}. Replacement of energy is required only once every Q/ω seconds (1 to 2 seconds). Helium is not cooled against the skin losses directly, but rather exposed to a low pressure, large volume, precooled gas dump chamber which is pumped down to a low temperature over a longer period of time. The gas dump chamber operates for a few minutes with no external power required. The dump chamber preferably is a large racetrack shaped ring buried around the resonator, with a minor radius of the order of 30 feet and a major diameter of 1000 feet. Such system may operate for about two minutes with no rise in the bath temperature of the resonator. In such period of operation about 1×10^6 liters of liquid helium bath would boil off.

In an emergency, resources of a major power grid would be diverted to sites at which this invention is installed. Some sites with magneto hydrodynamic generators capable of independent operation might also be used, but the diversion or use as the case may be would be of short duration.

Referring now to FIG. 2, the sphere **20** has been shown in greater detail and comprises an inner liner or wall **20***a* and an intermediate liner **20***b*. The zone **20***c* between liners **20***a* and **20***b* is a metallic honeycomb filled zone through which liquid helium is caused to flow to maintain the inner liner **20***a* at about the temperature of liquid helium, thus making it superconductive. Preferably, the inner liner **20***a* is a suitable metallic shell having a niobium or niobium alloy film thereon which may be made superconductive.

The outer shell **20***d* encompasses the intermediate shell **20***b* with a zone **20***e* therebetween which similarly has liquid hydrogen therein. Pipes **20***f* and **20***g* lead through the outer liner **20***d* to a gas dump, later to be described. More particularly, a plurality of pipes **20***f* and **20***g* extend radially from sphere **20** and are provided with valves **20***h* and **20***i*.

The sphere **20** is loaded on command with microwave energy from a plurality of generator sets such as the sets **30** and **31**. The generator set **30** is coupled to the sphere by way of an input channel **32**. The generator set **31** is connected into the sphere **20** by way of a channel **33**. The microwave generators **30** and **31** may comprise multiple units such as klystron tubes which are maintained at cryogenic temperatures. As illustrated in FIG. 2, several tubes are to be included in unit **31**, only one being shown. The tubes are identical and each includes a cathode **31***a* in a first cavity which leads to a buncher cavity **31***b* which in turn is connected to an output cavity **31***c*. The beam then passes through a magnetic deflecting unit **31***d* to a dump anode **31***e*. The output cavity **31***c* is connected by way of channel **31***f* to the input channel **33** leading to the sphere **20**. A grid is maintained at a very high potential, of the order of 200,000 volts, for operation at high power levels as will be described wherein a plurality of like tubes in each unit **30** and **31** are operated in parallel.

Generators **30** and **31** operate under the control of the radar control unit **35**. The control unit **35** controls the phase of microwaves in the various channels in unit **36** so that the beam from the radiating elements in antenna **10** can be focused or directed to any given direction above the plane defined by the phased array antenna elements. Targets are identified by the control unit **35** operating at low power supplied via channel **33***a*. In response to detecting a target a timer **37** is actuated by way of channel **38** to turn generators **30** and **31** on to high power thereby initiating high level flow of microwave energy into sphere **20**. Timer **37** also applies periodically a trigger pulse by way of channel **40** to each of a plurality of lasers. Only one laser **25** has been shown producing a laser beam which momentarily heats windows in the walls of the sphere **20** in order to dump the microwave energy stored therein into the wave guides **41** which lead to the phase controlled unit **36**. As indicated in FIG. 2, the laser beam **25***a* passes through while being partially reflected by a mirror **42**. The beam thus reflected is again reflected by a mirror **43** to impinge a window **44** in the wall of sphere **20**. The portion of the beam passing through mirror **42** illuminates and heats the skin on window **45**. The other windows similarly are simultaneously heated. The laser beams together with the structure of the window **44**, **45** etc. operate as dump switches. As indicated in FIG. 2, there are many dump switches located around the wall of the sphere **20**, only eight such window dump switches being shown in FIG. 2. The dump switches lead to the wave guide **41** so that the energy may be transmitted through the phase control unit to the various elements in the antenna **10** to radiate a high energy burst into the atmosphere and to the target to which the array **10** is directed.

In FIG. **3** the structure of the window **44** has been shown in section. A wave guide **44***a* passes through the wall of sphere **20** to the layer **20***a* which is a superconducting skin lining sphere **20**. A quartz plate **44***b* is mounted in the wave guide **44***a* immediately behind the layer **20***a*. The quartz layer is thus transmissive as to the laser beam **25***a* which is directed axially along the wave guide **44***a*. The quartz is a high dielectric material but capable of supporting the film **20***a* and capable of passing the microwaves stored in sphere **20** when film **20***a* on the face of the quartz plate **44***b* is heated by the laser beam **25***a* to a temperature above the superconducting temperature.

A modified form of the window is shown in FIG. **4**. In this modification, the film **20***a* is backed by a first quartz plate **44***b*. A second quartz plate **44***c* is positioned behind plate **44***b* and is spaced therefrom so that a flow channel **44***d* is created between the confronting surfaces of the quartz plates **44***b* and **44***c*. The wave guide **44***a* has perforations **44***e* therein registering with the zone between plates **44***b* and **44***c*. By this means, liquid helium may flow between the two quartz plates from the zone **20***c* lying between the liners **20***a* and **20***b* of FIG. **2**.

In FIG. **5** the system has been illustrated in a generalized form wherein the phased array antenna **10** is supported above the sphere **20**. The sphere **20** is provided with an outer cover or shell **60** within which all of the components of the radar may be mounted except that a base portion **61** will be provided to house the microwave generators and associated electronics. The entire volume within housing **60** and within the unit **61** will be maintained preferably at cryogenic temperature.

A reservoir of liquified helium is maintained available for heat transfer from the zone encompassed by shell **60**. More particularly, a plurality of radially extending tubes **70** and **71** lead to a chamber **72** which may be the racetrack shaped chamber above referred to. Valves **73** and **74** may be opened so that heat may be transmitted from components within the shell **60** to the reservoir of cooled helium in the chamber **72**. The liquid helium in chamber **72** would be maintained cool by conventional liquifying apparatus contained in the units **75** and **76**. Normally when the system is operating in the search and acquisition mode only, valves **73** and **74** will be closed. The system in units **75** and **76** would be maintained on an operative basis to keep the helium in chamber **72** liquified. When high power bursts are to be generated, the valves **73** and **74** are opened to make available for cooling the vast reservoir of helium in chamber **72**.

By way of example, the dimension (x) of the sphere **20** may be of the order of 60 feet. The maximum diameter (y) of the chamber **20** may be of the order of 1000 feet. The system would accommodate about two million liters of helium for cooling purposes.

Before a radar burst is triggered, the field level inside the resonator **20** is brought up to full power, requiring about 2×10^8 watts using beam power tubes as microwave source for excitation. This requires approximately one second.

The laser trigger pulse is applied via the wave guides through a quartz window **44***f*, FIG. **2**, located on each guide into the intended focal plane of each dump window. The focal plane in FIG. **3** is within the quartz window **44***b* in resonator **20** just behind the thin niobium film **20***a* so that very fast local heating is applied to the film via conduction in the quartz. Low temperature quartz conducts heat away from the thin niobium film caused by the passage of a high power microwave pulse during the dump operation. The thermal diffusivity of quartz below 5° K. is less than or about the same as a metal. Quartz makes an ideal dielectric backing and heat sink for low temperature applications. When the superconductor film **20***a* is operating near 2° K., a 200 A° thickness is sufficient to completely reflect the field and establish the resonator modes. When the temperature is raised locally about 5° to 10° K., the local skin depth in the film **20***a* increases and the material switches into the normal conducting state. In the normal state, the film represents only about 1% of a skin depth. The radiation escapes through the ports very rapidly, being coupled and impedance matched to the traveling wave guide mode at the same frequency. During the approximately one microsecond when the power is flowing through the film, the current density in the metal in the normal state is,

$$\bar{J}=\sigma E_w \alpha Q^2 E_w \tag{1}$$

where:

E_w=traveling wave amplitude;

σ=conductivity; and

Q=the Q of the liner **20***a*.

For a traveling mode to transmit the power from the cavity in time Δt requires a field E given by

$$\Delta t \frac{E^2}{8\pi} C = \frac{1\times10^8}{NS} \tag{2}$$

where N is the number of windows in area S each, C the speed of light. This means for NS approximately equal to one half the sperical resonator surface, and $\Delta t\approx1$ μsec. that $E_{peak}=5\times10^4$ volt/cm. After transmission to the high pressure horns in antenna **10**, this field level E_{peak} is finally reduced by increasing the radiating area to about ten times the resonator area to a value of about 1×10^6 volt/meter. Dealing with low temperature quartz behavior, the film **20***a* is thermally coupled to a diffusion depth approximately equal to 0.05 cm for 1 μsec. in the quartz. This provides a mass of about ten grams for a one microsecond pulse, and area approximately equal to 100 cm² per window. For a temperature rise not to exceed T=5° K. in the quartz to this depth, this requires no more than $\Delta E=M_Q C_Q \Delta T$ (where M_Q is the mass of the quartz, and C_Q is the specific heat of the quartz) joules be deposited in the film by the pulse. The pulse will carry 1×10^5 joules of electromagnetic energy per window. From the above relations, only about 200 joules can be accommodated and still use the low temperature quartz coupling. But this is the amount expected for the energy deposit, as the following shows: For the normal metal condition the cavity "Q" is known to drop to about 1×10^5 at 10° K. This means all the cavity energy would be absorbed in a time given by $Q/\omega=1\times10^{-5}$ sec. For 1% of a mean free path in the film (1% of a skin depth) only about 1×10^4 watts/cm² is deposited or about a few joules per microsecond per window. This is well within the capacity of the available heat sink. Note that if this energy were deposited only within the metal skin of area 100 cm², the temperature rise would be at least a few thousand degrees K., and would probably ablate the film.

In a phased array system, the microwave beam can be made very directional and approach a theoretical paraboloid reflector surface. The approximate angular width of the ½ energy points can be estimated from the relation for a paraboloid:

$$\theta=(7\times10^{4})/fD \qquad (3)$$

where

θ=beam angle in degrees;

f=frequency in megahertz; and

D=diameter of phased array (paraboloid) feet.

Hence, for a "baseline" or equivalent paraboloid diameter of 500 feet and f=10,000 Hz (3 cm. radiation), $\theta=2\times10^{-4}$ radian. At a range of 100 miles (500,000 feet) the main energy lobe covers about 100 feet. If D is measured in cm., f in c.p.s., and the angle θ in radians, $\theta=(3\times10^{10})/fD$.

A target having linear dimension, L, such that $L>>\lambda$, has a radar intercept cross section approximately equal to its geometrical projected area. Hence, if R=range in cm and δ=fraction of total pulse intercepted, $\delta=(\pi/2)(L/R)^2(D/\lambda)^2$. For example, if $L\approx5$ feet, R=500,000 feet, $(L/R)^2=1\times10^{-10}$, $(D/\lambda)=0.25\times10^{8}$, $\delta=\pi\times10^{-10}0.25\times10^{8}=0.005$ or ½%. At 33 miles, this is 4% and at 10 miles≈40%. A target moving at 5 mi./second would receive from 30-40 pulses in 100 miles at a rate of 2/second. The average energy is that intercepted at 33 miles in this case, being the average over range.

$$\langle\delta\rangle_R=\frac{\pi}{2}(D/\lambda)^2(L)^2\frac{1}{(R_{max}-R_{min})}\int_{R_{min}}^{R_{max}}\frac{dR}{R^2} \qquad (4)$$

Assuming $R_{max}\approx100$ miles, $R_{min}\approx10$ miles, a target either has (1) generated within it≈30, 200 kilobar shocks or (2) about 30, 20 kilobar shocks, plus an ablation of about 50 Kg of material causing a consequent change in momentum of about 1-10% and so a randomization of from one to ten miles in circular error probable. This depends upon whether the target (1) reflects part of the radiation with metallic like skin depths or (2) is very absorptive at X-band. In either case, components inside the target may be deformed and rendered inoperative. Tracking the target is done via phase shifting electronically in known manner as generally shown in U.S. Pat. Nos. 3,460,149 to Logan and 3,454,945 to Hyltin.

The target will not be able to manuever to avoid the burst since it travels at the speed of light. A target traveling at 5 miles a second could move only ten feet during a maximum range 100 mile transit time for the burst. It will be located near the center of the central lobe. It would move only 0.03 feet even for a one microsecond pulse duration.

For a 1×10^{8} joule system, and a one microsecond pulse, 1×10^{14} watts is radiated. At a field level of 1.5×10^{6} volt/meter, about 6×10^{9} watts/M^2 can be radiated. This requires a total radiating area of about 2×10^{4} M^2. Hence, a 100 meter square array will prevent atmospheric breakdown.

The system including cavity **20** then is a large honeycomb structure lined with a superconductor which is spherical and excited to a field level at the wall of about 1×10^{6} volt/cm. to avoid magnetic breakdown. This requires a radius of about ten meters to store 1×10^{8} joules, thus a 60 foot diameter sphere. The sphere is cooled by superfluid liquid helium in the honeycomb and surrounding bath. With little power this helium bath can be maintained against heat leak to the atmosphere via a simple dewar wall design.

During operation, a helium gas dump chamber, surrounding the cold liquid helium reservoir, is used to pump the helium vapor during an emergency; the void dewar is recycled and maintained at about 1.7° K. by ordinary vacuum pumps when not in emergency use, although over a much longer time. Coupling from the sphere **20** to the radiation impedance is accomplished by first vacuum wave guide transmission to each of vacuum side horn windows. From there the horns are high pressure inert gas (e.g. argon) coupled between the high vacuum side and the atmospheric window side. About 1000 horns with an exit area≈10 M^2 are employed in antenna **10**. They are part of the phased array radiation system and are preferably fed via about 100 dump switch areas on sphere **20**.

In conventional klystron tubes the pulse length obtainable is determined primarily by the electron beam dump anode. For example, tube **31** of FIG. **2** may be operated conventionally to generate a 10 megawatt pulse for a few microseconds by a 100 amp, 200,000 volt beam at about 50% efficiency at $\lambda\approx3$ cm (X-band).

The beam is generated at cathode **31***a*, accelerated by the 200,000 volt potential on grid **31***g* and sent through the buncher cavity **31***b*. The bunched beam is then drifted to maximum bunching time and then either put back through the same cavity (reflex klystron) or through an output cavity **31***c*. After this stage, high energy microwaves are extracted. The beam is still at 100 amperes at about 100,000 volts. This is a 10 megawatt beam. This beam is absorbed onto an anode. The anode can only absorb this energy for a short pulse time without over heating and destruction. Hence pulses of only a few microseconds have been possible.

In accordance with this invention means are provided to eliminate this drawback. Microwaves at 10 megawatts are generated, continuous wave. Some small skin losses in the cavity walls must be taken into account, but this is a relatively minor problem.

In this invention large cryogenic capacity is utilized. This is accomplished by employing two features:

(1) use of superconducting output cavities to eliminate wall skin losses, and

(2) allowing the electron beam to pass out from the output cavity into a vacuum region pipe through a port.

The beam is then passed through another resonant output cavity system (klystron) **31***f* and in like manner used over again several times until most of the beam energy is used up. It then is diverted through a superconducting magnet beam diverter and dumped onto a large absorbing and if necessary ablative anode. Alternately, the beams are decelerated through a D.C. potential to deliver residual power back to the power supply system.

With known techniques (100 amp, 200,000 volts), a continuously operating electron beam system of klystrons operates continuous wave.

In order to power up the main resonator with energy 1×10^{8} joules/sec=100 microwave, about 10 klystron power tubes are required. The unit may run continuously. It can be multiple stage and then diverted to the decelerating electrode **31***e*. Sphere **20** is fed from a continuous electron beam power tube system which may employ 2 to 5 tubes per beam and 2 to 5 beams.

Having described the invention in connection with certain specific embodiments thereof, it is to be understood that further modifications may now suggest themselves to those skilled in the art and it is intended to cover such modifications as fall within the scope of the appended claims.

What is claimed is:

1. A high energy microwave system for directing energy bursts of microwave radiation at a target comprising:
   - (a) a microwave cavity having superconducting walls for storing microwave energy,
   - (b) generating means for feeding waves of microwave energy into said cavity,
   - (c) transmitting means coupled to said cavity for directing microwave energy toward said target, and
   - (d) tracking means connected to said transmitting means for initiating flow of microwave energy to said cavity upon locating said target and triggering said transmitting means a predetermined time after initiating said flow to said cavity for directing a burst of electromagnetic energy to said target.

2. A defense system comprising:
   - (a) a phased array radar adapted to intercept and follow a target path including an antenna array and a low level channel of microwave energy for exciting the elements of said array to produce radar returns and define said path,
   - (b) a microwave storage reservoir,
   - (c) means to supply upon interception of said target a high level flow of microwave energy to said reservoir,
   - (d) microwave feed channels leading from said reservior to the elements of said antenna array,
   - (e) microwave dump switches at the juncture of said channels with said reservoir, and
   - (f) means responsive at least in part to said returns for actuating said dump switches for flow of bursts of microwave energy from said reservoir to said target via said antenna array.

3. The combination set forth in claim 2 wherein said reservoir is maintained at a temperature near 0° K. to prevent losses in the walls thereof.

4. The combination set forth in claim 2 wherein said dump switches comprises:
   - (a) wave guides extending to the wall of said reservoir,
   - (b) a superconductive layer lining said reservoir and covering each of said wave guides,
   - (c) a heat conductive dielectric member in each said wave guide backing said layer, and
   - (d) means to heat said member locally to change the conductivity of said layer at the mouth of each wave guide.

5. The combination set forth in claim 4 wherein said layer is of a niobium material and said dielectric member is quartz.

6. The combination set forth in claim 4 wherein said means to heat said dielectric member is a laser producing a beam directed onto said member.

7. A method of employing high level microwave energy bursts to do work on a moving target at a distance comprising:
   - (a) locating and tracking said target with low energy microwave radar transmissions,
   - (b) upon locating said target initiating flow of high level microwaves to cryogenically controlled storage, and
   - (c) after reaching a predetermined level of energy in storage abruptly dumping said energy via the same path as said radar transmissions to impact said target by locally heating exit locations in the walls of said storage to trigger dumping of said energy.

8. A defense method comprising:
   - (a) operating a phased array radar to intercept and follow a target path by focusing an antenna array in a low level channel of microwave energy to produce radar returns defining said path,
   - (b) supplying upon interception of a target a high level flow of microwave energy to a cryogenic microwave storage reservoir, and
   - (c) responsive at least in part to said returns, actuating localized zones in the walls of said reservoir to render them transmissive for dumping microwave energy from said reservoir onto said target through said antenna array.

9. A high energy microwave system for directing energy bursts of microwave radiation at a target comprising:
   - (a) a microwave reservoir of the order of 10 meters radius lined with a niobium layer,
   - (b) a liquid helium system to maintain said layer superconducting during storage of microwave energy in said reservoir,
   - (c) generating means for feeding microwave energy into said reservoir,
   - (d) wave guides leading from said reservoir,
   - (e) a phased array radar means coupled to said wave guides for directing microwave energy from said reservoir toward said target,
   - (f) a quartz barrier closure for each of said wave guides contacting said barrier in heat transfer relation, and
   - (g) laser means connected to said phased array radar means for heating said quartz to cause flow of microwave energy from said reservoir in predetermined relation to flow of energy to said reservoir.

(57) **ABSTRACT**

An RFDE system includes an RFDE transmitter and at least one RFDE antenna. The RFDE transmitter and antenna direct high power electromagnetic energy towards a target sufficient to cause high energy damage or disruption of the target. The RFDE system further includes a targeting system for locating the target. The targeting system includes a radar transmitter and at least one radar antenna for transmitting and receiving electromagnetic energy to locate the target. The RFDE system also includes an antenna pointing system for aiming the at least one RFDE antenna at the target based on the location of the target as ascertained by the targeting system. Moreover, at least a portion of the radar transmitter or the at least one radar antenna is integrated within at least a portion of the RFDE transmitter or the at least one RFDE antenna.

MULTIFUNCTIONAL RADIO FREQUENCY DIRECTED ENERGY SYSTEM

TECHNICAL FIELD

The present invention relates generally to radio frequency directed energy (RFDE) systems, and more particularly to multifunctional type RFDE systems.

BACKGROUND OF THE INVENTION

Radio frequency directed energy (RFDE) systems are known in the art for directing high power RF, microwave and/or millimeter wave electromagnetic energy to destroy or disrupt a target. Although RFDE systems typically serve as military weapons, RFDE systems need not be limited to weapon systems. For example, RFDE systems of the present invention may be used for non-military purposes such as destroying or disrupting foreign objects, contaminants, undesirable atmospheric conditions, or other types of targets.

As for weapon systems, it is important to distinguish between an RFDE weapon system and an electronic warfare system. A primary difference between an RFDE weapon and an electronic warfare system is power and kill mode. An electronic warfare system makes use of a priori knowledge of a target it is designed to jam or disrupt. An electronic warfare system uses such a priori knowledge of a target's characteristics (e.g., frequency of operation, method of operation, etc.) to disrupt or confuse the target with "finesse", or a relatively low amount of power.

On the other hand, an RFDE weapon system can go after a broad range of targets (electronics, biological, ordinance, structures, etc.) due to its relatively large radiated power. A priori knowledge of the intended target characteristics is typically not required because the RFDE weapon either burns-out or overwhelms its target by the shear amount of power it radiates.

An ongoing problem with RFDE systems is targeting—accurately pointing the RF directed energy beam at the intended target and establishing an accurate range from the system to the target. To date, the RFDE system targeting problem has been addressed by using what may be referred to as auxiliary add-on systems. These add-on systems could include a stand-alone radar system, a stand-alone laser range finder, stand-alone optical or infrared imaging system, etc. However, these add-on systems add significant cost to the RFDE system. In addition, these add-on systems add significant complexity by requiring calibration of the alignment between the RFDE system and the stand-alone targeting system.

FIG. **1** is a block diagram of a typical RFDE system **10**. In its simplest form, the system **10** includes a high power transmitter **12** transmitting thru a high power antenna **14**. The transmitter **12** operates at RF, microwave or millimeter wave frequencies. The system **10** operates based on a prime power source **16**, such as an AC mains, generator, high capacity battery system, etc. A power conditioning block **18** conditions power delivered from the power source **16** so as to be suitable for powering the transmitter **12**. A cooling system **20** provides appropriate cooling to the power conditioning block **18** and the high power transmitter **12** as needed. A control block **22** provides appropriate control among the various sub-systems.

The RFDE weapon system **10** further includes an antenna pointing system **24** for aiming the high power antenna **14**, and thus the high power electromagnetic energy beam transmitted therefrom, at the target. The pointing system **24** typically is driven by coordinate data identifying the direction and range of the intended target. Such coordinate data is provided by a stand-alone targeting system **26**. As is noted above, the targeting system **26** is an add-on often in the form of a stand-alone radar system, a stand-alone laser range finder, stand-alone optical or infrared imaging system, etc. As is also noted above, however, these add-on systems add significantly to the cost and complexity of the RFDE system.

In view of the aforementioned shortcomings associated with conventional RFDE systems, there is a strong need in the art for an RFDE system which is not subject to the cost and complexity associated with conventional targeting systems.

SUMMARY OF THE INVENTION

The RFDE system of the present invention eliminates the need for a separate, stand-alone targeting system by integrating a targeting system within the RFDE system itself. The RFDE system is multi-functional in that all or part of the RFDE system hardware that functions to direct high power electromagnetic energy also functions to obtain and provide targeting information to aim the high power electromagnetic energy beam. For example, the RFDE transmitter is not only used as the source of the directed electromagnetic energy, but is also used as a radar transmitter for targeting an object. A relatively simple radar receiver may then be added to the RFDE system. The cost of the overall system is substantially reduced since an expensive radar transmitter is not required.

Moreover, the complexity of the system is reduced as calibration of the alignment between the RFDE system and a stand-alone targeting system becomes unnecessary.

According to one aspect of the invention, a multi-functional RFDE system is provided. The RFDE system includes an RFDE transmitter and at least one RFDE antenna. The RFDE transmitter and antenna direct high power electromagnetic energy towards a target sufficient to cause high energy damage or disruption of the target. The RFDE system further includes a targeting system for locating the target. The targeting system includes a radar transmitter and at least one radar antenna for transmitting and receiving electromagnetic energy to locate the target. The RFDE system also includes an antenna pointing system for aiming the at least one RFDE antenna at the target based on the location of the target as ascertained by the targeting system. Moreover, at least a portion of the radar transmitter or the at least one radar antenna is integrated within at least a portion of the RFDE transmitter or the at least one RFDE antenna.

According to another aspect of the invention, a method is provided operating an RFDE system. The method includes the steps of utilizing an RFDE transmitter and at least one RFDE antenna to direct high power electromagnetic energy towards a target sufficient to cause high energy damage or disruption of the target; utilizing a targeting system to locate the target, the targeting system including a radar transmitter and at least one radar antenna for transmitting and receiving electromagnetic energy to locate the target; aiming the at least one RFDE antenna at the target based on the location of the target as ascertained by the targeting system; and integrating at least at portion of the radar transmitter or the at least one radar antenna within, at least a portion of the RFDE transmitter or the at least one RFDE antenna.

To the accomplishment of the foregoing and related; ends, the invention, then, comprises the features hereinafter fully described and particularly pointed out in the claims. The following description and the annexed drawings set forth in detail certain illustrative embodiments of the invention. These embodiments are indicative, however, of but a few of the various ways in which the principles of the invention may be employed. Other objects, advantages and novel features of the invention will become apparent from the following detailed description of the invention when considered in conjunction with the drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1** is a block diagram of a conventional RFDE system;

FIG. **2** is a block diagram of a multi-functional RFDE system in accordance with a first embodiment of the present invention;

FIG. **3** is a block diagram of a multi-functional RFDE system in accordance with a second embodiment of the present invention;

FIG. **4** is a block diagram of a multi-functional RFDE system in accordance with a third embodiment of the present invention;

FIG. **5** is a block diagram of a multi-functional RFDE system in accordance with a fourth embodiment of the present invention;

FIG. **6** is a block diagram of a multi-functional RFDE system in accordance with a fifth embodiment of the present invention;

FIG. **7** illustrates a multi-functional RFDE system mounted within an aircraft in accordance with an embodiment of the present invention;

FIG. **8** illustrates a multi-functional RFDE system mounted within a wheeled vehicle in accordance with an embodiment of the present invention; and

FIG. **9** is a schematic diagram of a multi-functional RFDE system incorporating a reflector-type antenna in accordance with an embodiment of the present invention.

DETAILED DESCRIPTION OF THE INVENTION

The present invention will now be described with reference to the drawings, in which like reference numerals are provided to refer to like elements throughout.

The RFDE system of the present invention integrates a targeting system, such as a radar targeting, system, into an otherwise conventional RFDE system. There are several ways that the targeting system can be integrated into the RFDE system as explained herein. The particular embodiments described below are meant to be merely exemplary. The present invention contemplates not only the particular embodiments described herein, but any system in which a targeting system is integrated in part or in whole within the RFDE system.

Referring to FIG. **2**, an RFDE system **30** is shown in accordance with an embodiment of the present invention. Since many of the elements of the RFDE system **30** in FIG. **3** are similar to those in the conventional system **10** discussed above with respect to FIG. **1**, only the relevant differences with be discussed herein for sake of brevity. In this particular embodiment, a portion of an otherwise conventional RFDE system (notably the high power transmitter **12** and/or the transmit antenna **14**) forms part of the targeting system. Specifically, during a targeting mode, the high power RFDE transmitter **12** is controlled by the control block **22** to transmit standard radar tracking signals thru the antenna **14**. The radar tracking signals may be any type of conventional radar signal such a pulse or continuous wave radar. The power level of the tracking signals may be a high powered signal, such as the RFDE signal itself, or a relatively low powered signal as more typical in radar tracking applications.

In the embodiment of FIG. **2**, a separate radar receiver **32** and radar receive antenna **34** are used in conjunction with the integrated RFDE/radar transmitter **12**. In one embodiment, the RFDE high power output beam intended to destroy or disturb a target is transmitted using the RFDE/radar transmitter **12** and antenna **14**. The radar receive antenna **34** receives portions of the RFDE output beam reflected by the target back towards the system **30**. The radar receiver **32** processes the reflected return signals using conventional techniques in order to identify the location of the target. For example, the radar receiver **32** can be coherently linked to the transmitted RFDE output waveform (represented by line **36**) so that Doppler processing can be achieved and the direction and range of the target identified.

The radar receiver **32** provides the target location information to an integrated targeting system block **38** which feeds the location information to the antenna pointing system **24**. Such operation allows the antenna **14** to be directed in both search and track radar functions.

As will be appreciated, the RFDE system **30** in FIG. **2**, as with the various other embodiments of the invention described herein, can operate in both an RFDE mode and a tracking mode. Both modes may be carried out simultaneously as described above, for example, where the high power electromagnetic energy output waveform of the RFDE system also serves as the radar tracking system transmit signal. Alternatively, the RFDE system **30** may switch between the RFDE mode and the tracking mode using a separate RFDE high power beam and lower power radar transmit signals, respectively. So long as the system **30** switches between the two modes rapidly enough so as not to lose track of the target, operation between RFDE mode and tracking mode may be time-division multiplexed.

Typically the radar transmitter is one of the most expensive portions of a radar tracking system. Therefore, by using the RFDE transmitter **12** and antenna **14** to function as the radar transmitter and antenna for targeting, the cost of the targeting system can be drastically reduced. Also, using the radar return of the RFDE high power beam itself to determine the target location can substantially improve the beam pointing accuracy of the RFDE system **30**. By using the RFDE high power beam to determine the location of the target, the power density on target will be maximized when standard radar tracking techniques are employed (e.g., monopulse, continuous scan, etc.).

Those of ordinary skill will appreciate that the RFDE transmitter **12** can be any transmitter suitable for transmitting an RFDE high power beam. For example, the RFDE transmitter **12** may be a single or multiple tube source, or solid state source. Moreover, it will be appreciated that the antenna **14** can be any type of suitable high power antenna which can be mechanically and/or electronically pointed and scanned via the antenna pointing system **24**. The transmitter/antenna can also be comprised of an active electronically steered array (AESA), for example, where an array of high power amplifiers/antennas is utilized. The radar receive antennas **34** can be any type of suitable antenna for receiving the radar return signals. As with the antenna **14**, the radar receive antenna **34** is mechanically and/or electronically pointed and scanned via the antenna pointing system **24**. The antenna pointing system **24** can be a mechanical gimbal or a beam steering computer controlling phase shifters in an electronically steerable array.

FIG. **3** illustrates another embodiment representing how a tracking system can be integrated with an RFDE system. The embodiment of FIG. **3**, as with the other embodiments described herein, shares many of the same elements as FIG. **2**, and thus again only the relevant differences between the embodiments will be discussed for sake of brevity.

Specifically, FIG. **3** illustrates an RFDE system **40** in which the power amplifier of the tracking system is integrated within the power amplifier of the RFDE system. More particularly, the RFDE transmitter **12** includes a low power RFDE signal source **42** operating at a first frequency and input to an adder **44**. The output of the adder **44** is input to a power amplifier **46** which amplifies the output before being radiated by the transmit antenna **14**. A low power radar signal source **48** at a second frequency is also input to the adder **44**. In addition, the low power radar signal source **48** is input to the radar receiver **32** to provide for coherent processing. The adder **44** thus outputs the combined RFDE signal source and radar signal source to the power amplifier **46**. The power amplifier **46** can be any suitable type of amplifier including, for example, an injection locked magnetron, a klystron, a solid-state amplifier, etc., or an array of any of these types of amplifiers in an AESA embodiment.

In the embodiment of FIG. **3**, a separate low power radar signal from the signal source **48** is used. This signal is combined with the RFDE signal from the RFDE signal source **42** prior to the combined signal being amplified by the power amplifier **46**. The frequencies of the RFDE signal and the radar signal do not have to be at the same frequency. In fact, they can be completely independent of each other within the bandwidth constraints of the power amplifier **46** and the RFDE transmit antenna **14**. It will be appreciated that significant isolation can be achieved between the RFDE and radar signals by filtering out the RFDE signal at the receive antenna **34** and/or radar receiver **32**.

Again, it will be appreciated that the RFDE system **40** of FIG. **3** may operate in an RFDE mode and a targeting mode. As in the other embodiments described herein, such modes may be carried out simultaneously or in time-multiplexed fashion. In the case where the RFDE signal source **42** and radar signal source **48** are different, one may consider such operation as frequency-multiplexed as will be appreciated.

FIG. **4** illustrates yet another embodiment of the present invention. In this embodiment, the RFDE system **50** integrates the radar receive antenna into the same antenna **14** serving as the RFDE and radar transmit antenna. This is accomplished by means of a high power circulator **52** which routes the RFDE/radar transmit signals from the shared transmitter **12** through to the antenna **14**. Reflected signals received by the antenna are routed by the circulator **52** to the receiver **32** for processing. In this example, as in the others discussed herein, the RFDE transmit signal may also be the radar transmit signal. The return signal is received by the same antenna **14** and coupled through the circulator **52** to the receiver **32**. The radar system thus can provide target information feedback to the antenna pointing system **24**.

The high power circulator **52** can be problematic in that it can be difficult to design a circulator that can handle the typical total power radiated by an RFDE system. Nevertheless, with improvements in materials and technologies such a circulator may someday be commercially feasible. Furthermore, the embodiment of FIG. **4** certainly is very suitable for an AESA system where the output power is broken-up among an array of transmit elements as discussed in more detail below.

In some integrated RFDE/targeting applications it may be desirable only to share the antenna between the RFDE and targeting systems. The RFDE system and the targeting system otherwise operate independently. An example of such an embodiment is shown in FIG. **5**.

Specifically, the embodiment of FIG. **5** illustrates a radar system **32'** which functions essentially independently of the RFDE system **60** with the exception of sharing a dual polarized antenna **14**. The RFDE system transmits the RFDE high power beam from the transmitter **12** via the dual polarized antenna **14** using one polarization (e.g., vertical, right hand circular, etc.). The radar system **32'**, with its own transmitter/receiver, transmits the radar transmit signal via the antenna **14** using the orthogonal polarization (e.g., horizontal, left hand circular, etc.). The reflected radar return signal received by the antenna **14** is processed by the radar system **32'** to provide target location information, again using conventional techniques. As in the other embodiments, the location information is provided to the integrated targeting system **38** which provides the information to the antenna pointing system **24**. The embodiment of FIG. **5** can be used to provide tracking information and/or is especially suitable for providing range information for the RFDE system.

FIG. **6** illustrates an embodiment in which AESAs or phased array antennas may be incorporated within the present invention. The embodiment of FIG. **6** is fundamentally the same as the embodiment of FIG. **3**, with the exception that the power amplifier **46** is represented by an array of power amplifiers **46'** included with the RFDE/radar transmit AESA antenna **14**. The radar receive antenna **34** may similarly comprise an AESA antenna.

As is shown in FIG. **6**, the combined signal from the adder **44** is input to a power splitter **72** within the AESA antenna **14**. The power splitter **72** separates the signal and provides the split signal to respective phase shifters **74** and power amplifiers **46'** corresponding to respective radiator elements **14'** in the antenna **14**. The antenna pointing system **24** may steer the antenna **14** by adjusting the phase of the phase shifters **74**, as will be appreciated.

Continuing to refer to FIG. **6**, it will further be appreciated that the radar source **48** and RFDE source **42** can be at different frequencies and still radiate in the same direction. As long as the phase shifters **74** are selected to provide a true time delay (which is fairly common in the art), the antenna **14** may be steered concurrently for both frequencies.

A multifunctional RFDE system of the present invention can be employed on a variety of platforms. For example, FIG. **7** illustrates an embodiment in which the system is employed on an aircraft. The combined RFDE/radar transmitter **12** and antenna **14** (not shown), for example, are mounted to radiate out the side of the aircraft. A pod is then mounted beneath the aircraft, containing the radar receiver **32** and receive antenna **34** (also not shown).

FIG. **8** shows an embodiment in which the RFDE system of the present invention can be employed on a wheeled vehicle. For example, the RFDE and radar systems are mounted in the back of the vehicle and share a common antenna. One possible such system **80** is shown in FIG. **9**. A high power RFDE source **12** radiates into a beam transport system comprised of mirrors (e.g., **82**) suitable for the frequency of operation. A cross-polarized radar transmit signal from the radar system **32'** is then injected into the RFDE beam path by means of a beam combiner/splitter **84**. The RFDE and radar transmit signal are then simultaneously transmitted from the common antenna **14**, in this embodiment a reflector-type antenna. The radar return signal is received by the antenna **14** and directed back to the cross-polarized radar system **32'** via the mirrors **82** and beam combiner/splitter **84**.

Although the invention has been shown and described with respect to certain preferred embodiments, it is obvious that equivalents and modifications will occur to others skilled in the art upon the reading and understanding of the specification. For example, although the present invention has been described primarily in the context of a conventional radar based targeting system, other types of radar-like targeting systems which rely on the transmission and return of electromagnetic energy (e.g., laser-based, infrared, etc.) can also be used without departing from the scope of the invention.

The present invention includes all such equivalents and modifications, and is limited only by the scope of the following claims.

What is claimed is:

1. A multi-functional radio frequency directed energy (RFDE) system, comprising:

an RFDE transmitter and at least one RFDE antenna for directing high power electromagnetic energy towards a target sufficient to cause high energy damage or disruption of the target;

a targeting system for locating the target, the targeting system including a radar transmitter and at least one radar antenna for transmitting and receiving electromagnetic energy to locate the target; and

an antenna pointing system for aiming the at least one RFDE antenna at the target based on the location of the target as ascertained by the targeting system,

wherein at least a portion of the radar transmitter or the at least one radar antenna is integrated within at least a portion of the RFDE transmitter or the at least one RFDE antenna to provide simultaneous transmission of the high power electromagnetic energy and the electromagnetic energy to locate the target.

2. The multi-functional RFDE system of claim **1**, wherein the at least one radar antenna is embodied at least partially within the at least one RFDE antenna.

3. The multi-functional RFDE system of claim **1**, wherein the radar transmitter is embodied at least partially within the RFDE transmitter.

4. The multi-functional RFDE system of claim **3**, wherein the radar transmitter and the RFDE transmitter comprise a common RF power amplifier.

5. The multi-functional RFDE system of claim **4**, wherein the electromagnetic energy for locating the target is at a first frequency, and the high power electromagnetic energy is at a second frequency different from the first.

6. The multi-functional RFDE system of claim **1**, wherein the at least one radar antenna functions to transmit the electromagnetic energy for locating the target, and the at least one radar antenna is embodied at least partially in the at least one RFDE antenna.

7. The multi-functional RFDE system of claim **6**, wherein the at least one radar antenna includes a first radar antenna that functions to transmit the electromagnetic energy for locating the target and to transmit the high power electromagnetic energy, and a second radar antenna that functions to receive the electromagnetic energy reflected from the target in order to locate the target.

8. The multi-functional RFDE system of claim **7**, wherein the first radar antenna comprises a multi-element phased array.

9. The multi-functional RFDE system of claim **6**, wherein the at least one radar antenna that functions to transmit the electromagnetic energy for locating the target also functions to receive the electromagnetic energy reflected from the target in order to locate the target.

10. The multi-functional RFDE system of claim **9**, wherein the at least one radar antenna comprises a dual-polarized antenna.

11. The multi-functional RFDE system of claim **1**, wherein the system comprises a beam combiner for combining the high power electromagnetic energy with the electromagnetic energy for locating the target in a path between the RFDE transmitter and the RFDE antenna.

12. The multi-functional RFDE system of claim **1**, wherein the system is configured for operation in a mobile vehicle.

13. The multi-functional RFDE system of claim **12**, wherein the mobile vehicle is a wheeled-vehicle.

14. The multi-functional RFDE system of claim **12**, wherein the mobile vehicle is an aircraft.

15. A method of operating a multi-functional radio frequency directed energy (RFDE) system, comprising the steps of:

utilizing an RFDE transmitter and at least one RFDE antenna to direct high power electromagnetic energy towards a target sufficient to cause high energy damage or disruption of the target;

utilizing a targeting system to locate the target, the targeting system including a radar transmitter and at least one radar antenna for transmitting and receiving electromagnetic energy to locate the target;

aiming the at least one RFDE antenna at the target based on the location of the target as ascertained by the targeting system; and

integrating at least a portion of the radar transmitter or the at least one radar antenna within at least a portion of the RFDE transmitter or the at least one RFDE antenna to provide simultaneous transmission of the high power electromagnetic energy and the electromagnetic energy to locate the target.

16. The method of claim **15**, wherein the at least one radar antenna is embodied at least partially within the at least one RFDE antenna.

17. The method of claim **15**, wherein the radar transmitter is embodied at least partially within the RFDE transmitter.

18. The method of claim **17**, wherein the radar transmitter and the RFDE transmitter comprise a common RF power amplifier.

19. The method of claim **18**, wherein the electromagnetic energy for locating the target is at a first frequency, and the high power electromagnetic energy is at a second frequency different from the first.

20. The method of claim **15**, wherein the at least one radar antenna functions to transmit the electromagnetic energy for locating the target, and the at least one radar antenna is embodied at least partially in the at least one RFDE antenna.

21. A multi-functional radio frequency directed energy (RFDE) system, comprising:

an RFDE transmitter and at least one RFDE antenna for directing high power electromagnetic energy towards a target sufficient to cause high energy damage or disruption of the target;

a targeting system for locating the target, the targeting system including a radar transmitter and at least one radar antenna for transmitting and receiving electromagnetic energy to locate the target; and

an antenna pointing system for aiming the at least one RFDE antenna at the target based on the location of the target as ascertained by the targeting system,

wherein at least a portion of the radar transmitter or the at least one radar antenna is integrated within at least a portion of the RFDE transmitter or the at least one RFDE antenna and the high power electromagnetic energy is used as the electromagnetic energy to locate the target.

22. A method of operating a multi-functional radio frequency directed energy (RFDE) system, comprising the steps of:

utilizing an RFDE transmitter and at least one RFDE antenna to direct high power electromagnetic energy towards a target sufficient to cause high energy damage or disruption of the target;

utilizing a targeting system to locate the target, the targeting system including a radar transmitter and at least one radar antenna for transmitting and receiving electromagnetic energy to locate the target;

aiming the at least one RFDE antenna at the target based on the location of the target as ascertained by the targeting system; and

integrating at least a portion of the radar transmitter or the at least one radar antenna within at least a portion of the RFDE transmitter or the at least one RFDE antenna,

wherein the high power electromagnetic energy is used as the electromagnetic energy to locate the target.

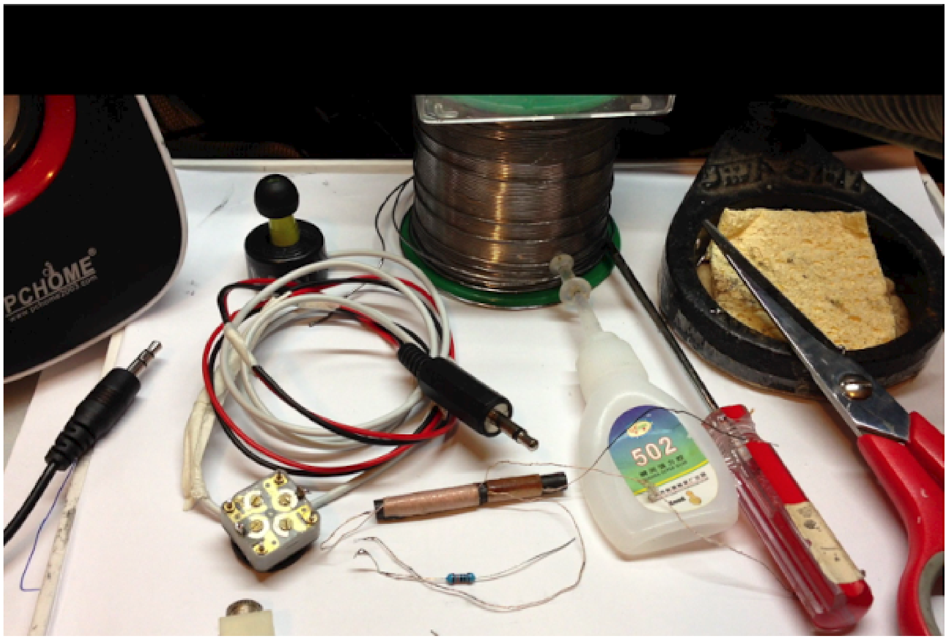
[http://2.bp.blogspot.com/-FYzx5aqFfVM/UVGOaN0HeBI/AAAAAAAAAxQ/XQtWPgoL_VQ/s1600/IMG_1098.JPG]

Parts you'll need

1. Variable Capacitor 360 pf - from an old radio.
2. Coil wound on a Ferrite Powder Rod - from an old radio e.g. old Walkman
3. A Crystal Earphone or a PC speaker with builtin amplifier.
4. Germanium Diode IN60
5. Resistor 100 Kohm
6. 3.5mm earphone jack
7. A small plastic box,
8. some wires .
9. Solder iron.
10. Antenna - 20 meters hanging vertically or horizontally at a high location (Warning : Lightning Hazard)
11. Ground - connect a wire to your metal water pipe.

[http://www.blogger.com/blogger.g?blogID=2311644141825422235]



[http://4.bp.blogspot.com/-QqxK3OffVq4/UVLe8yWkFzI/AAAAAAAAAxo/4vtNVM1EUMY/s1600/parts.png]

You can get most of these from electronic ships in Shamshupo, except parts #1,2 & 3.
For the variable capacitor and the coil you can easily buy some old recycled walkman or old radios for HKD20-50 from the hawkers in Ip Liu Street in Sham Shui Po. The other way is to go to taobao.com to buy them online and ship to HK. The goods is RMB 5, but the shipping fees is minimum RMD 30, so not worth it unless you buy in great quantity.
For the Crystal Earphone, it's very hard to buy nowadays. Refer to my other post to make one yourselves. DIY Crystal Earphone for Crystal Radios [http://billydiy.blogspot.com/2013/03/build-crystal-earphone-for-crystal.html]

Remember to leave me some comments (at the comment box) at the bottom of this if you have read this blog.

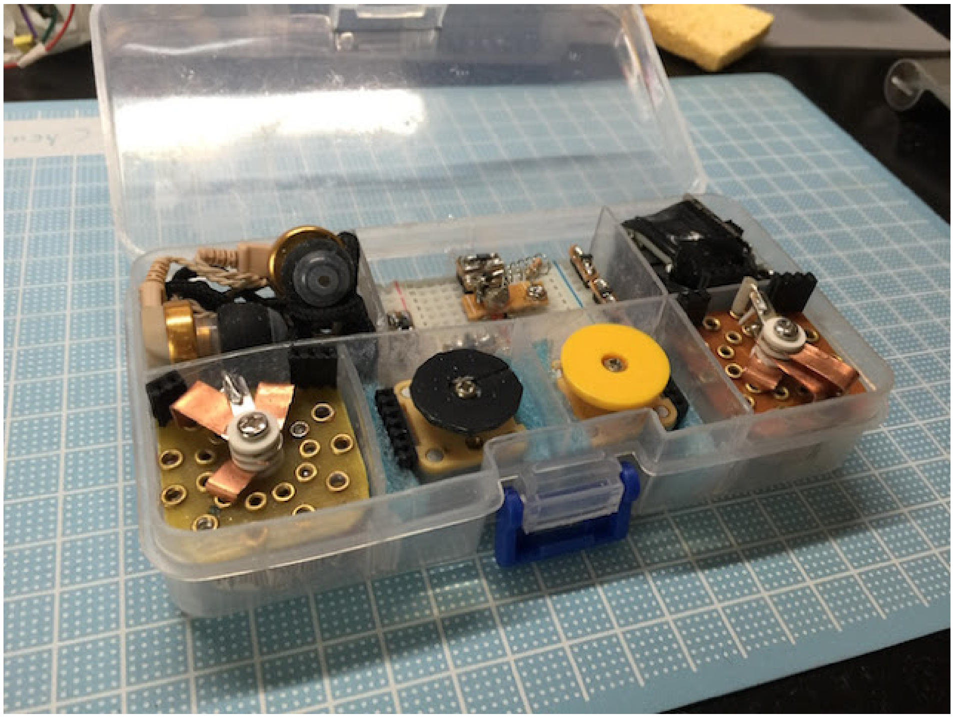
DIY Tiny portable crystal radio laboratory 135 x 70 x 30 mm



Inspired by skywave's traveling crystal set. I built this DIY Tiny (135 x 70 x 30 mm in size.) portable crystal radio laboratory.
I found a tiny sorting box made of low loss material (pp) and start to put things in:
- a couple of the DIY tiny multi-pole rotary switches (that I built) soldered in with the ferrite coils. I used 31mm ferrite core with100u permeability and Litz wire of 0.04 mm x 60 threads (see the picture below for the no. of turns).The shortest handle of the rotary switch selects the number of turns of the antenna coil. The longest handle selects the tapping point of the detector in the tank coil. The one in the middle selects the number of turns of the tank coil to match with the tuning capacitor
- a couple of 2x270pf plastic variable capacitor.
- a pair of 150 ohm hearing aid ear buds (total 300 ohm).
- a tiny 200K to 300 ohm audio transformer that I purchased from taboo.com soldered in with switches for the different way to connect , e.g. 200k to 300 ohm for my hearing aid ear buds, or just connect 200K in parallel with my piezoelectric ear bud.
The transform can be improved as its not ideal to have impedance fixed at 200k. I am trying to open it up to see if I can add additional taps without breaking the hair thin wires inside.
- A breadboard with the following different types of detectors
-- Crystal
-- BAT85
-- 1N60

-- 1N34A
-- 1SS86 x 2
-- HSM 2820 x 2
-- HSM 2850 x 2
-- 3SK143-Q (*3DQ) x 2
-- 33K resistor to work with 3DQ.
- Connecting wires (hidden under the breadboard).
- Tiny 50uA DC current meter (stilling trying to find one. So far I can only find a tiny 500uA meter that does not move much as the crystal radio current is so small). If I ever find one, it'll take the place currently used by the earbud.

I tried this in the hotel room when traveling and got good results.
- Tested using my 700mm umbrella loop antenna.
- Tested by hanging 3 meters of horizontal wire at the top of the curtain inside the room. [https://4.bp.blogspot.com/-Uq_TZea4wT4/VwBnupV99NI/AAAAAAAACeQ/OMB8y1i7TUsNOj0Eox2Ag9o-DGAV79HJw/s1600/IMG_6921.JPG]

What is a crystal?

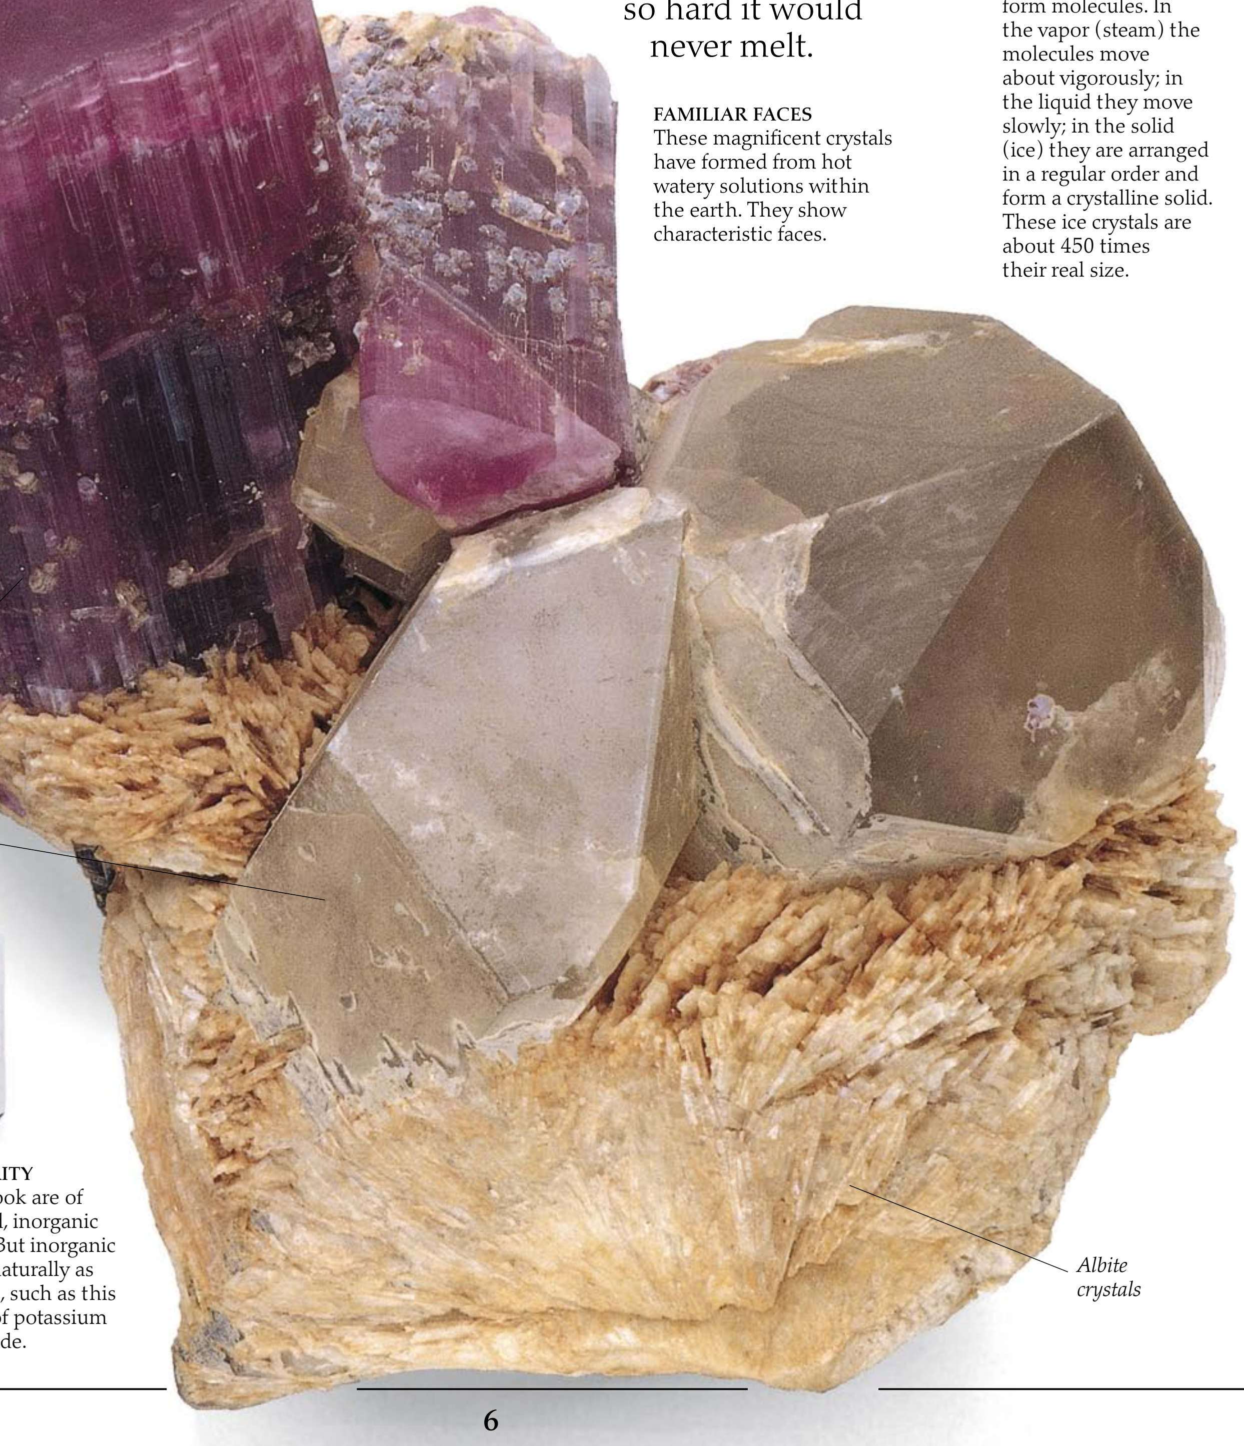
CRYSTALS ARE ASSOCIATED WITH PERFECTION, transparency, and clarity. Many crystals fit these ideals, especially those cut as gemstones, but most are neither perfect nor transparent. Crystals are solid materials in which the atoms are arranged in a regular pattern (pp. 14–15). Many substances can grow in characteristic geometric forms enclosed by smooth plane surfaces. They are said to have crystallized, and the plane surfaces are known as faces. The word *crystal* is based on the Greek word *krystallos*, derived from *kryos*, meaning icy cold. In ancient times it was thought that rock crystal, a colorless variety of quartz, was ice that had frozen so hard it would never melt.

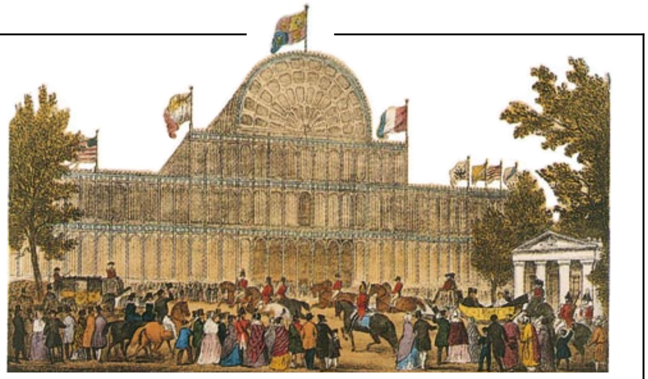
STATES OF MATTER
A material can exist as a solid, a liquid, or a gas depending on its temperature. Water is made of atoms of hydrogen and oxygen bound together to form molecules. In the vapor (steam) the molecules move about vigorously; in the liquid they move slowly; in the solid (ice) they are arranged in a regular order and form a crystalline solid. These ice crystals are about 450 times their real size.



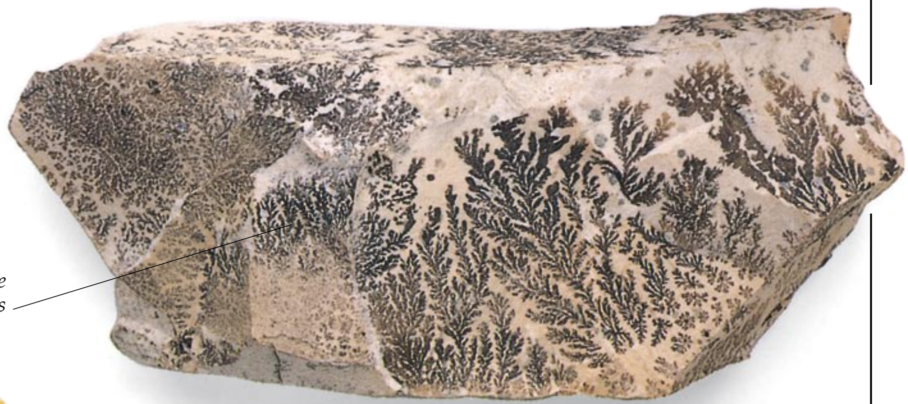
FAMILIAR FACES
These magnificent crystals have formed from hot watery solutions within the earth. They show characteristic faces.

CRYSTAL MINORITY
Most crystals in this book are of naturally occurring, solid, inorganic materials called minerals. But inorganic compounds not found naturally as minerals also form crystals, such as this artificially grown crystal of potassium magnesium sulfide.

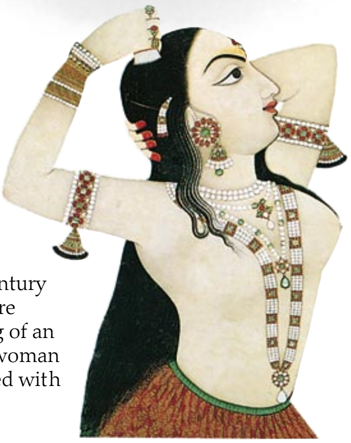
MASSIVE MINERAL
Crystals only grow large and perfect in the right conditions. Most grow irregularly and the faces are often difficult to distinguish. This specimen of the mineral scapolite consists of a mass of small, poorly formed crystals. Minerals in this form are described as massive.



GLASS HOUSE
The Crystal Palace was built for the Great Exhibition of London of 1851, but was destroyed by fire in 1936. The roof and outer walls were made of nearly 300,000 panes of glass – not crystals.



CRYSTAL LINING
These fern-like growths look like a plant but are in fact crystalline growths of the mineral pyrolusite. Such crystals are called dendrites (p. 21) and are often found lining joints and cracks in rocks.

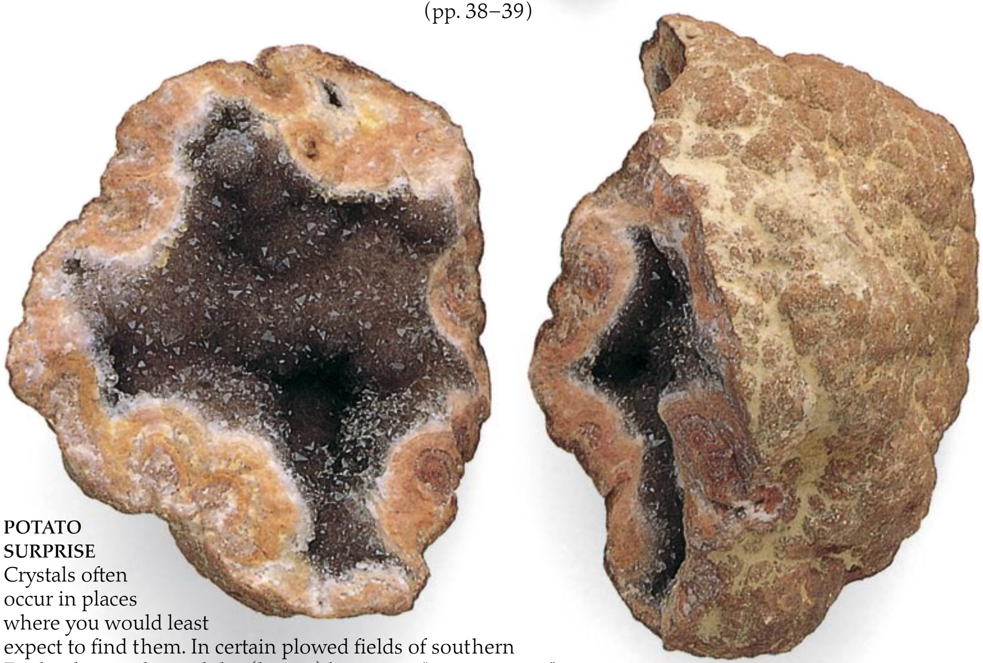


18th-century miniature painting of an Indian woman bedecked with jewelry

Cut heliodor (pp. 38–39)

Cut aquamarine (pp. 38–39)

GEM OF A CRYSTAL
Most gemstones are natural crystals chosen for their beauty, durability, and, in many instances, rarity. They are usually cut and polished (pp. 58–59). Crystals with the same composition and properties as naturally occurring minerals can now be grown artificially (pp. 26–27) and cut as gemstones.

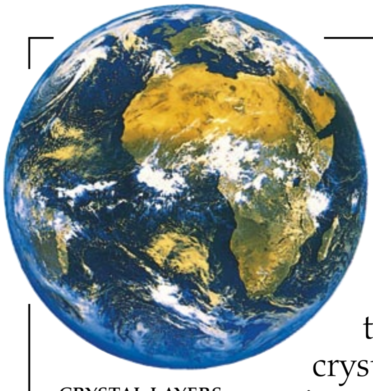


POTATO SURPRISE
Crystals often occur in places where you would least expect to find them. In certain plowed fields of southern England, irregular nodules (lumps) known as "potato stones" are found. When broken open, they often reveal sparkling crystals.

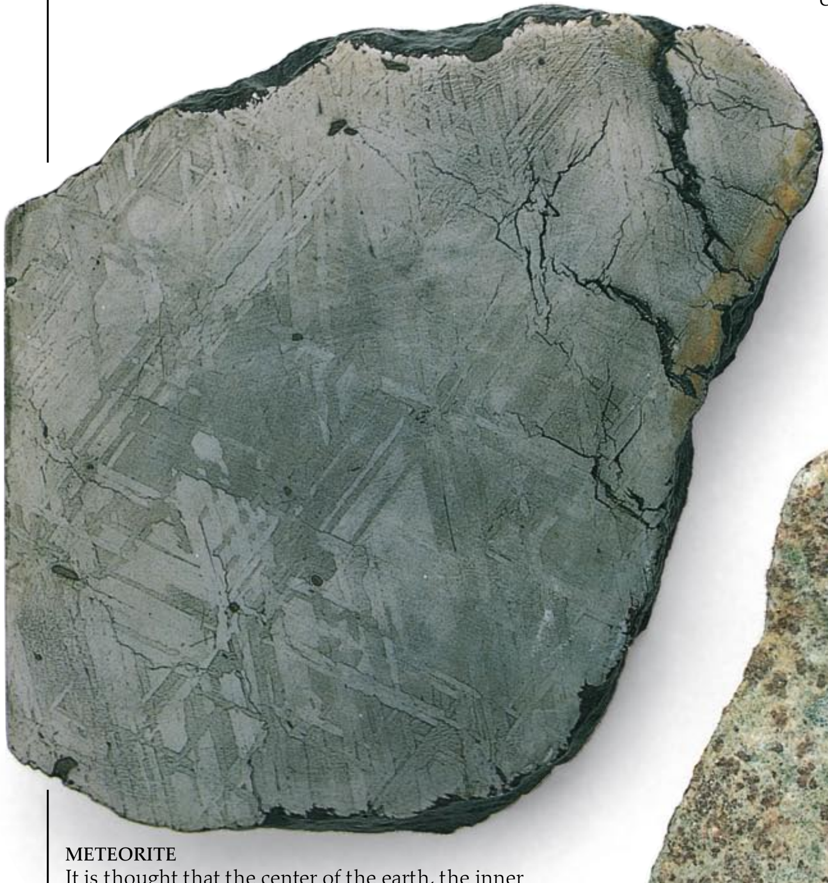
MOST IRREGULAR
Some of the objects which we know as "crystal" are glass and are not truly crystalline. Glass has little structure, as it is cooled too quickly for the atoms to arrange themselves into a regular order, and is said to be amorphous.

A world of crystals

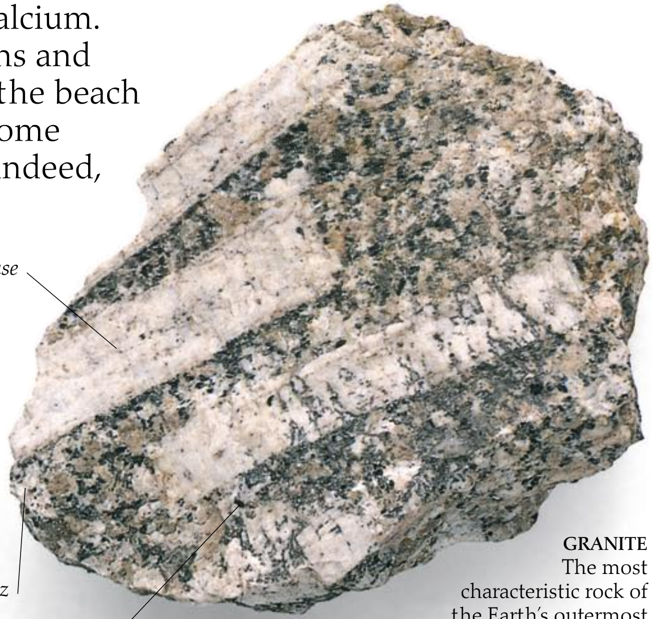
Crystals are all around us. We live on a crystal planet in a crystal world. The rocks which form the earth, the moon, and meteorites – pieces of rock from space – are made up of minerals and virtually all of these minerals are made up of crystals. Minerals are naturally occurring crystalline solids composed of atoms of various elements. The most important of these are oxygen, silicon, and six common metallic elements including iron and calcium. Crystalline particles make up mountains and form the ocean floors. When we cross the beach we tread on crystals. We use them at home (pp. 62–63) and at work (pp. 28–29); indeed, crystals are vital to today's technology.



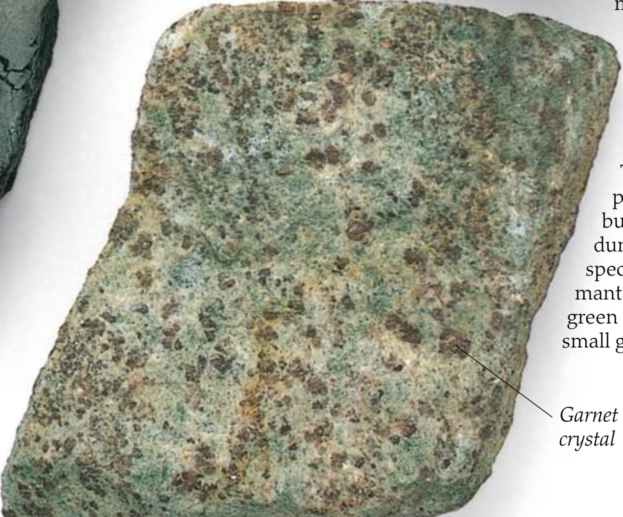
CRYSTAL LAYERS
The earth is formed of three layers: the crust, the mantle, and the core. These are made mostly of solid rock-forming minerals. Some rocks, such as pure marble and quartzite, are made of just one mineral, but most are made of two or more.



METEORITE
It is thought that the center of the earth, the inner core, may be similar in composition to this iron meteorite. It has been cut, polished, and acid-etched to reveal its crystalline structure.

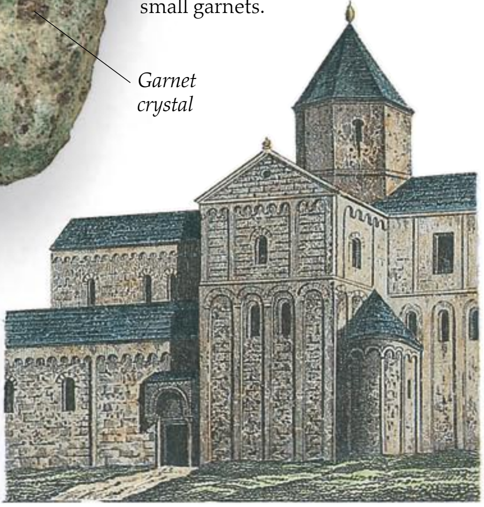


GRANITE
The most characteristic rock of the Earth's outermost layer, the continental crust, is granite. It consists mainly of the minerals quartz, feldspar, and mica. This specimen shows very large crystals of the feldspar mineral orthoclase, with small crystals of quartz and biotite mica.



ECLOGITE
The earth's upper mantle is probably mostly peridotite but other rocks include dunite and eclogite. This specimen, originally from the mantle, is eclogite containing green pyroxene and small garnets.

LIQUID ROCK
Molten lava from inside the earth can erupt from volcanoes such as the Kilauea volcano, Hawaii, shown here. When the lava cools, minerals crystallize and it becomes a solid rock.



CRYSTAL STRENGTH
Most buildings are made of crystals. Both natural rock and artificial materials are mostly crystalline, and the strength of cement depends on the growth of crystals.

DOWN TO DUST
Pebbles, sand, and the greater part of soil are all formed from eroded rocks. Eventually, they will be eroded even further to form dust in the air (p. 32). Like the rocks they come from, these familiar things are all made up of crystals.

Feldspar crystal

Basalt pebble

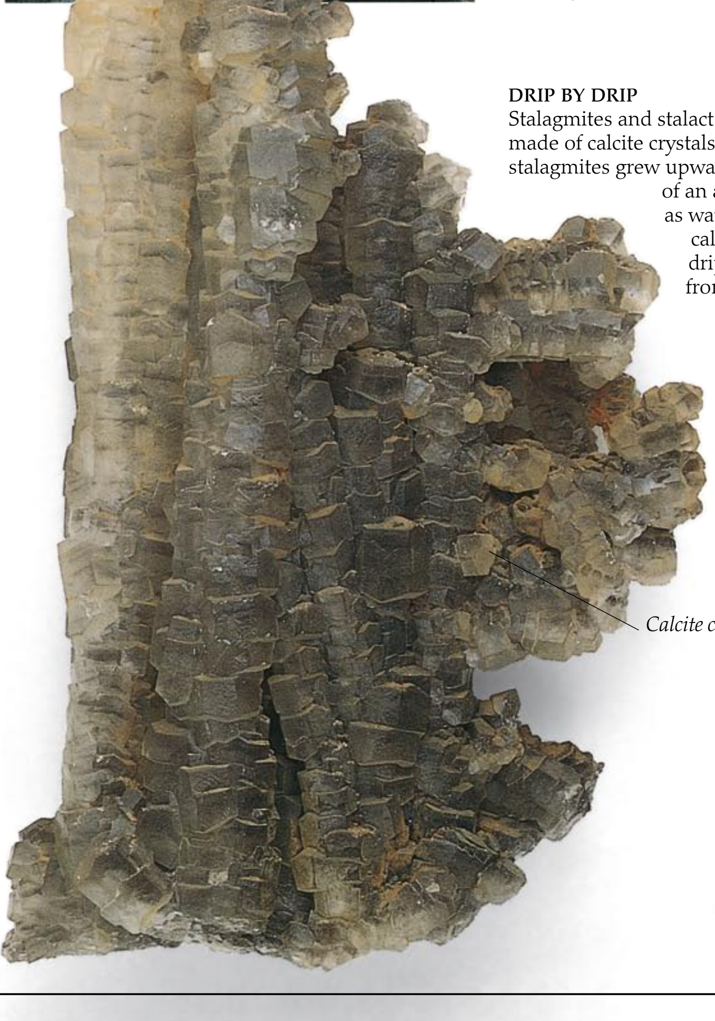
Quartzite pebbles

Quartz sand grains

Soil

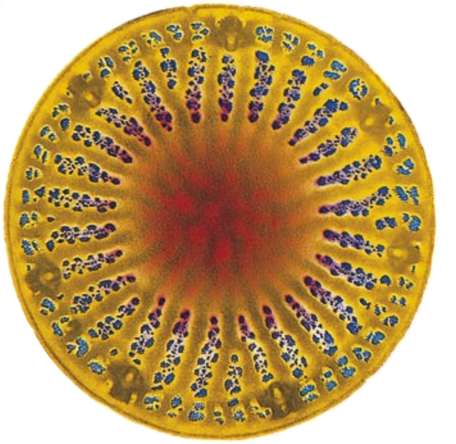
CRYSTAL CAVE
Fine stalactites and stalagmites form the spectacular scenery in these grottoes of Giita in Lebanon.

DRIP BY DRIP
Stalagmites and stalactites are mostly made of calcite crystals. This group of stalagmites grew upward from the floor of an abandoned mine as water, rich in calcium carbonate, dripped down from above.



Organic crystals

Crystals do not only grow in rocks. The elements that make up most rock-forming minerals are also important to life on earth. For example, minerals such as calcite and apatite crystallize inside plants and animals.



MICROCRYSTALS
This microscope picture of a diatom, *Cyclotella pseudostelligera*, shows a symmetrical (even) structure. Diatoms are microscopic algae whose cell walls are made up of tiny silica crystals.

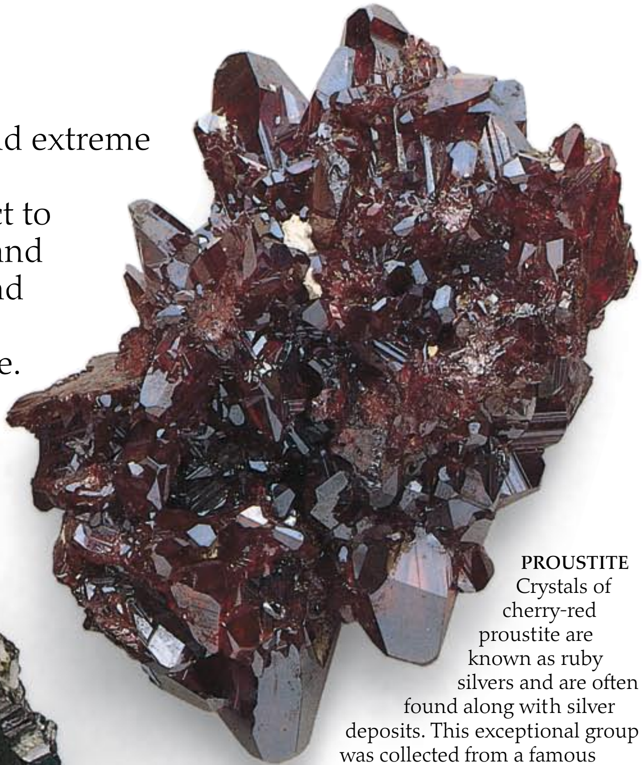
ANIMAL MINERAL
Gallstones sometimes form inside an animal's gall bladder. This gallstone from a cow has exactly the same crystalline composition as struvite, a naturally occurring mineral.

STRESSFUL
Adrenaline is a hormone, a substance produced by the body to help it cope with stress. This greatly enlarged picture of adrenaline shows it is crystalline.

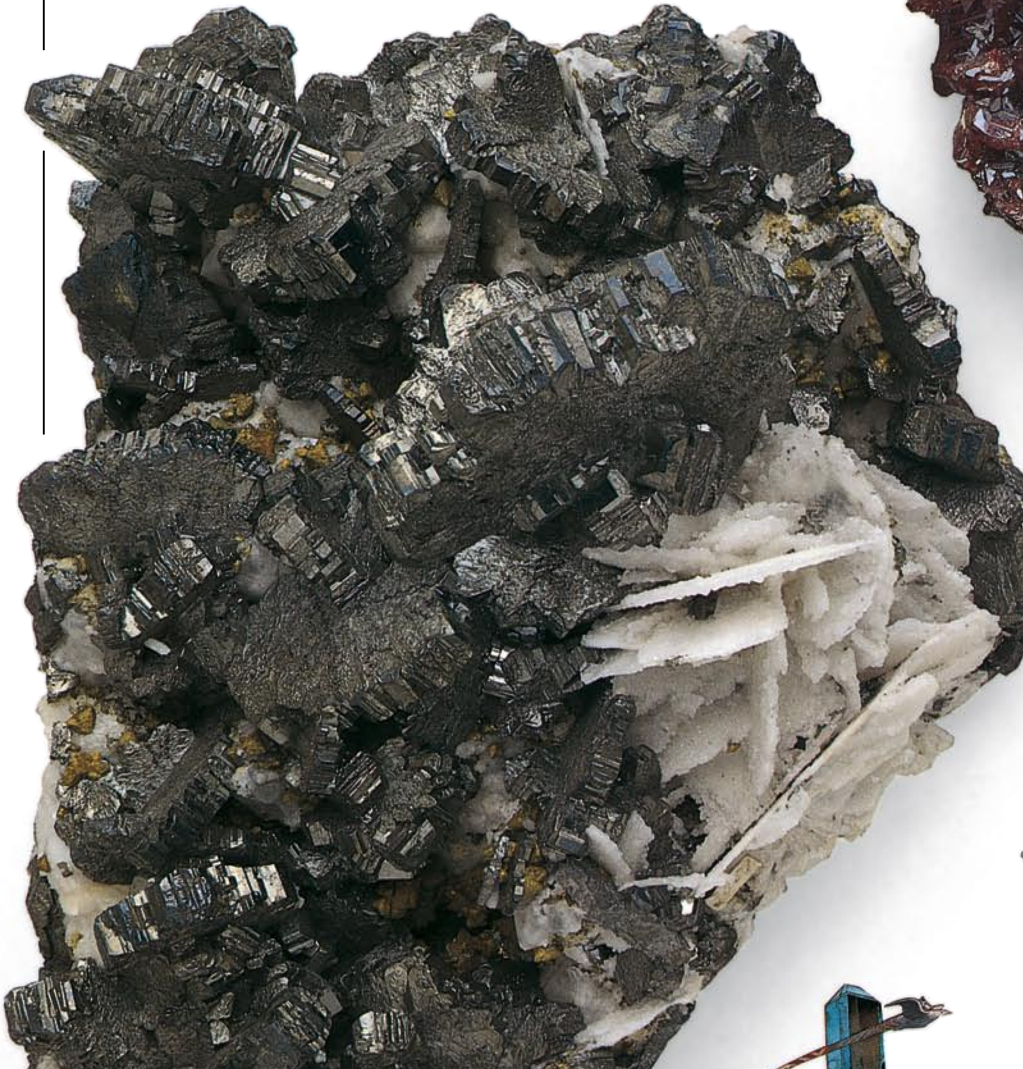
HUMAN APATITE
Bones contain tiny crystals of the mineral apatite. They make up the skeleton in vertebrate mammals – those that have a backbone, such as humans and horses. This is a human humerus (upper arm bone).

Natural beauty

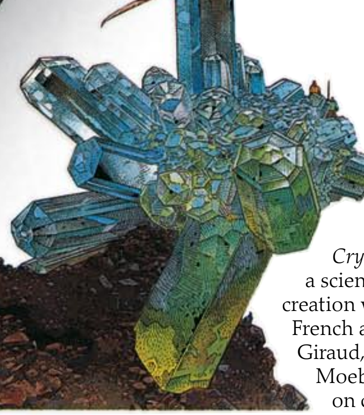
Well-formed crystals are objects of great beauty and extreme rarity. Conditions have to be just right for them to grow (pp. 20–21) and any later changes in conditions must act to protect rather than destroy them. Even if they do grow and survive, many are destroyed by people during mining and other activities. Survivors are therefore of great interest. The crystals shown are about 60 percent of their real size.



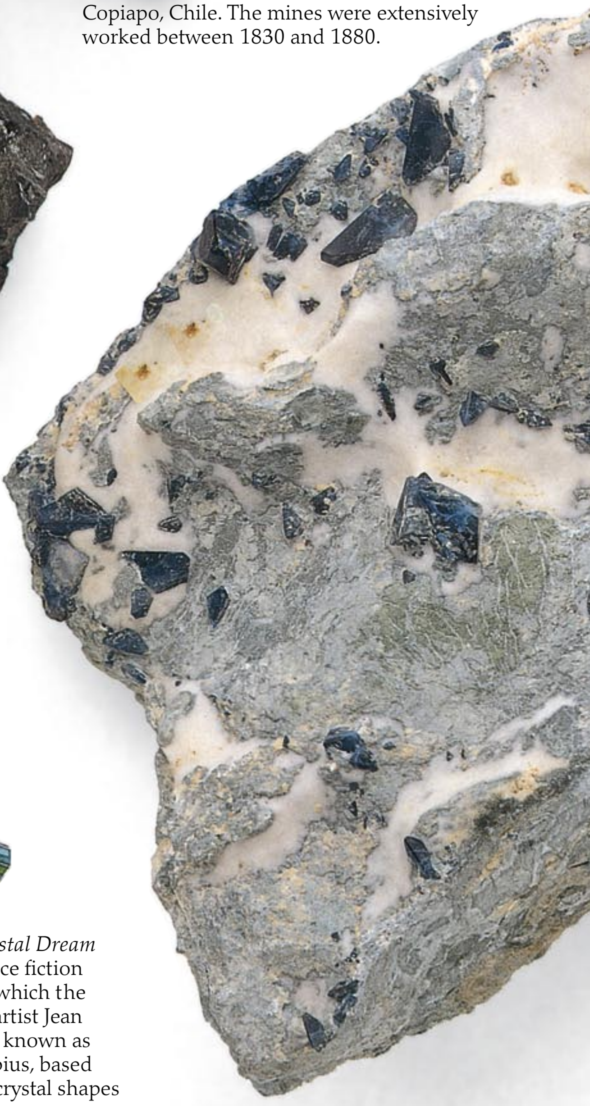
PROUSTITE
Crystals of cherry-red proustite are known as ruby silvers and are often found along with silver deposits. This exceptional group was collected from a famous silver mine area at Chanarcillo, Copiapo, Chile. The mines were extensively worked between 1830 and 1880.

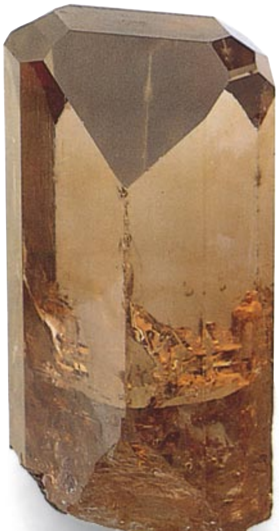


BOURNONITE
These magnificent bright-gray "cogwheel" crystals were collected from the Herodsfoot lead mine in Cornwall, England. Between 1850 and 1875 this mine produced bournonite crystals of a quality still unsurpassed elsewhere.

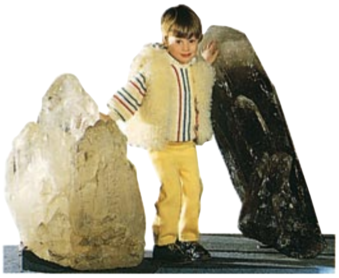


Crystal Dream a science fiction creation which the French artist Jean Giraud, known as Moebius, based on crystal shapes

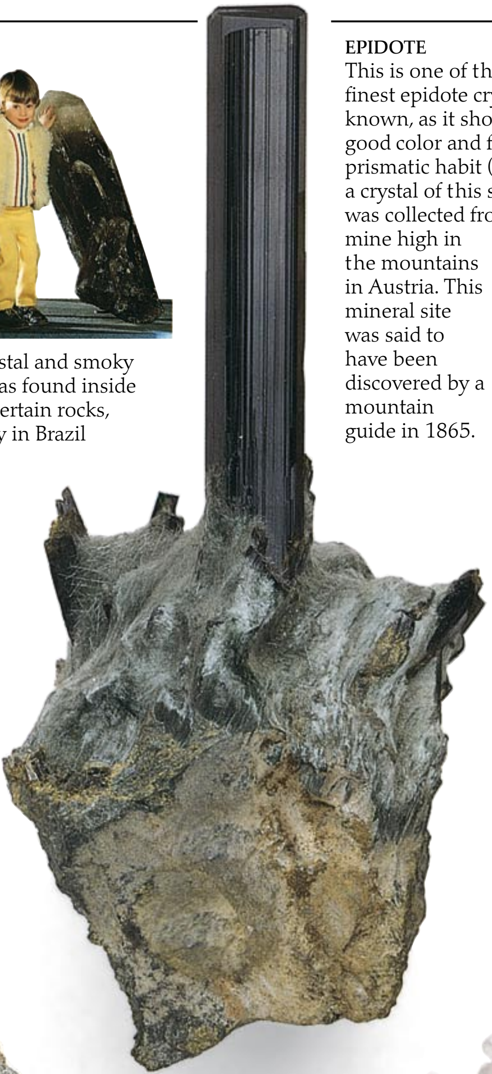




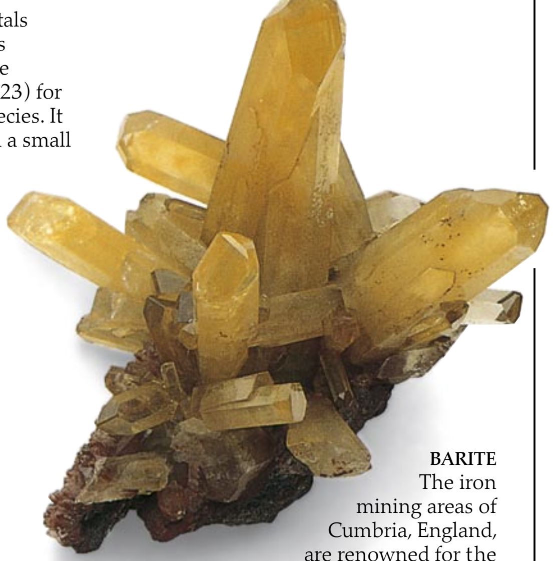
TOPAZ
This perfect topaz crystal was one of many wonderful crystals that were found in the last century close to the Urulga River in the remote areas of the Borshchovochnyy Mountains in Siberia. Most were yellowish brown and some weighed up to 22 lb (10 kg).



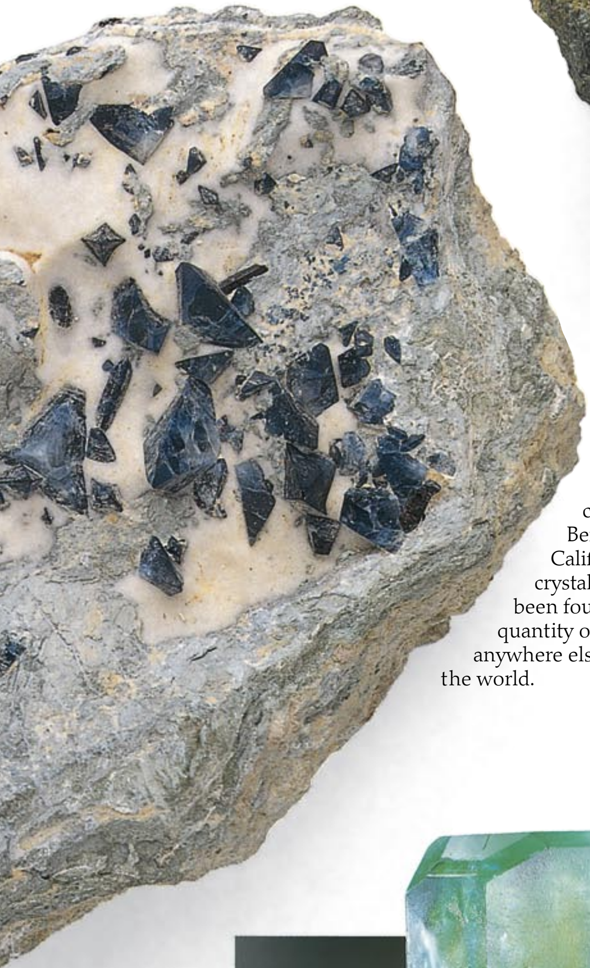
Giant rock crystal and smoky quartz crystal, as found inside cavities in certain rocks, especially in Brazil



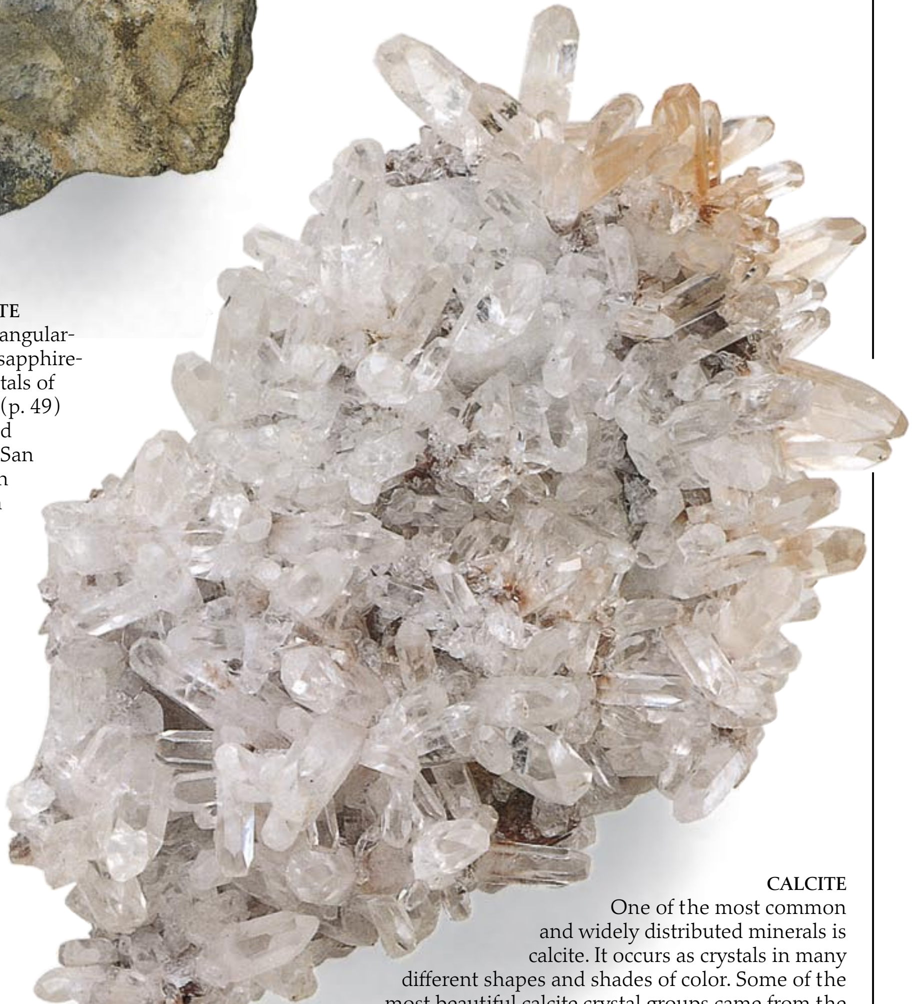
EPIDOTE
This is one of the finest epidote crystals known, as it shows good color and fine prismatic habit (p.23) for a crystal of this species. It was collected from a small mine high in the mountains in Austria. This mineral site was said to have been discovered by a mountain guide in 1865.



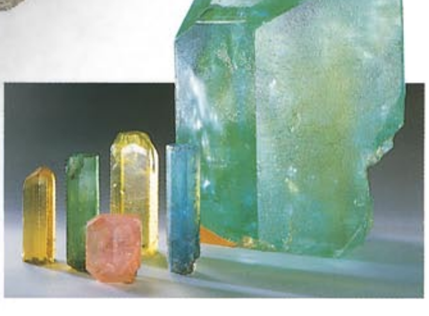
BARITE
The iron mining areas of Cumbria, England, are renowned for the quality of their barite crystals. The crystals display a range of colors, and each color comes mostly from one mine. These golden-yellow crystals came from the Dalmellington mine, Frizington, where many fine specimens were collected during the 19th century.



BENITOITE
These triangular-shaped, sapphire-blue crystals of benitoite (p. 49) were found close to the San Benito River in California. Such crystals have not been found in this quantity or quality anywhere else in the world.



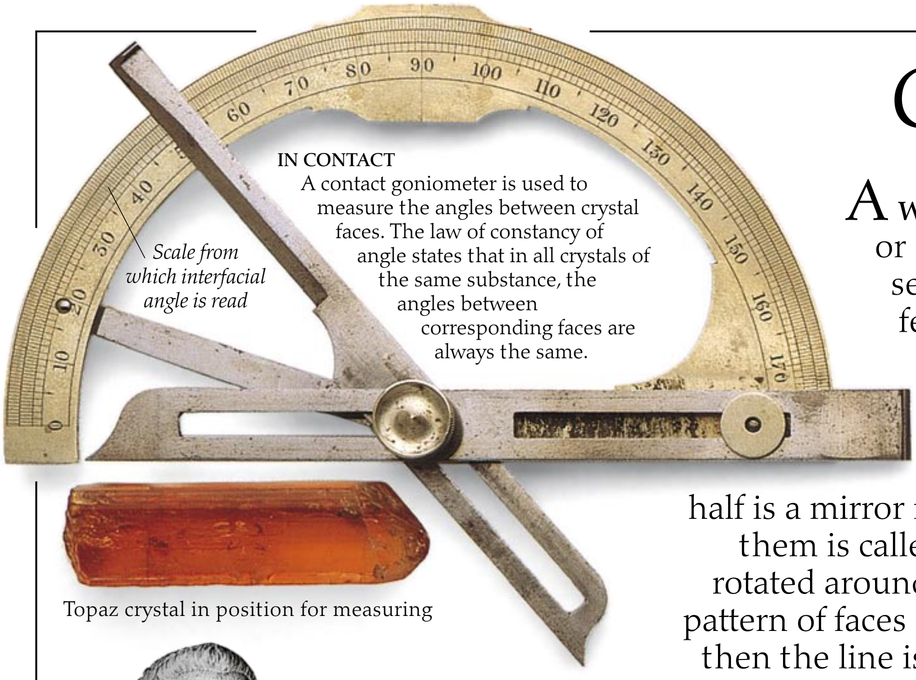
CALCITE
One of the most common and widely distributed minerals is calcite. It occurs as crystals in many different shapes and shades of color. Some of the most beautiful calcite crystal groups came from the Egremont iron mining area of Cumbria, England, in the late 19th century. This typical example consists of many fine colorless crystals, some of which are slightly tinged with red.



Beautifully formed beryl crystals from various parts of the world

Crystals–outside...

A WELL-FORMED CRYSTAL has certain regular or symmetrical features. One feature is that sets of faces have parallel edges. Another feature of many crystals is that for every face, there is a parallel face on the opposite side. Crystals may have three types of symmetry. If a crystal can be divided into two, so that each half is a mirror image of the other, the line that divides them is called a "plane of symmetry." If a crystal is rotated around an imaginary straight line and the same pattern of faces appears a number of times in one turn, then the line is an "axis of symmetry." Depending on how many times the pattern appears, symmetry around an axis is described as twofold, threefold, fourfold, or sixfold. If a crystal is entirely bounded by pairs of parallel faces then it has a "center of symmetry."

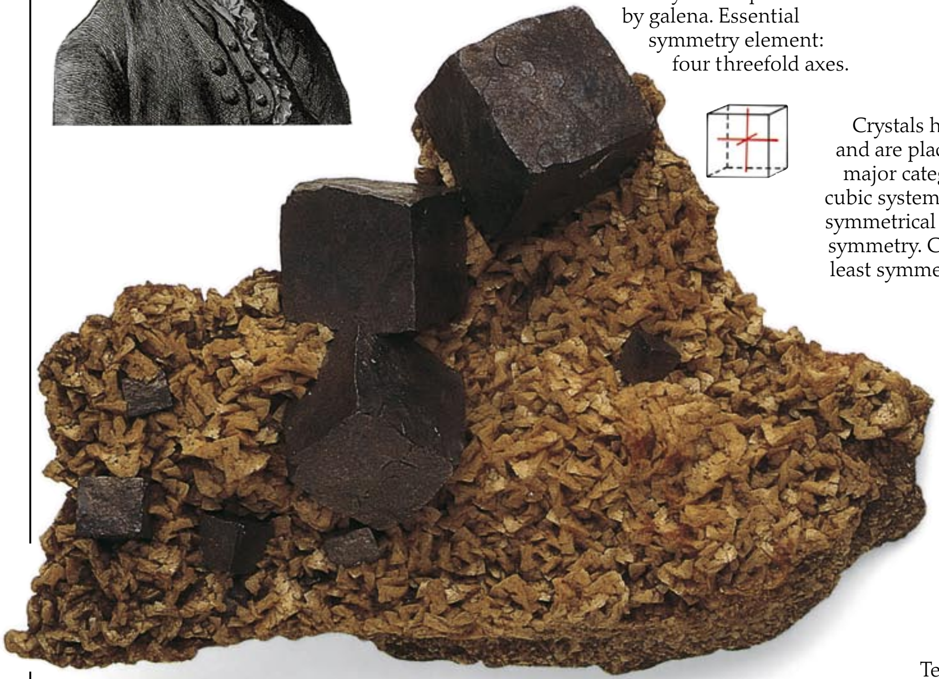


IN CONTACT
A contact goniometer is used to measure the angles between crystal faces. The law of constancy of angle states that in all crystals of the same substance, the angles between corresponding faces are always the same.

Scale from which interfacial angle is read

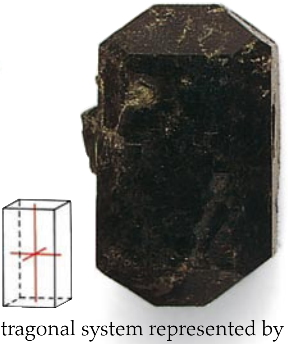
Topaz crystal in position for measuring

Romé de l'Isle (1736-90), who established the law of constancy of angle first proposed by the scientist Steno in 1669

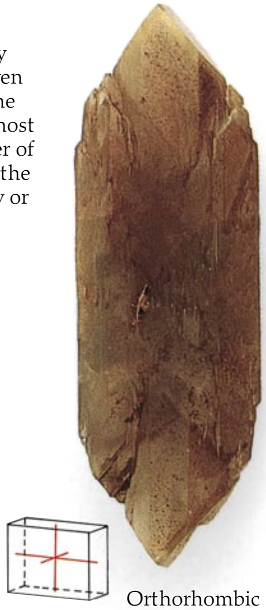


Cubic system represented by galena. Essential symmetry element: four threefold axes.

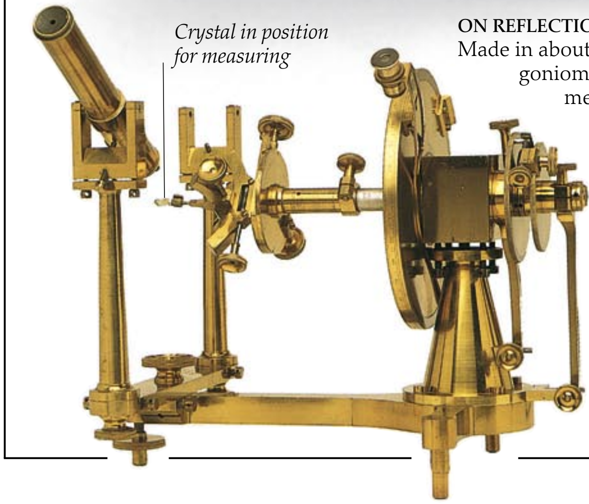
SEVEN SYSTEMS
Crystals have differing amounts of symmetry and are placed, according to this, in one of seven major categories called systems. Crystals in the cubic system have the highest symmetry. The most symmetrical have 9 planes, 12 axes, and a center of symmetry. Crystals in the triclinic system have the least symmetry with only a center of symmetry or no symmetry at all.



Tetragonal system represented by idocrase. Essential symmetry element: one fourfold axis.

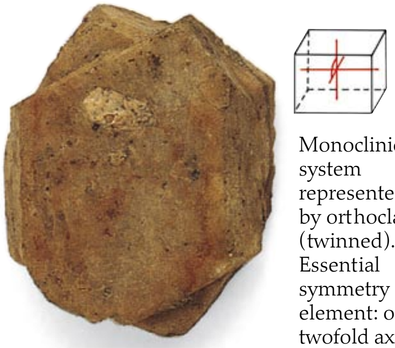


Orthorhombic system represented by barite. Essential symmetry element: three twofold axes.

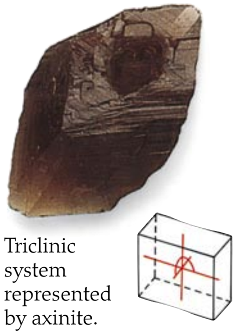


Crystal in position for measuring

ON REFLECTION
Made in about 1860, this optical goniometer is designed to measure the interfacial angles of small crystals by the reflection of light from their faces. The crystal is rotated until a reflection of light is seen from two adjacent faces. The angle between the two faces is read off the graduated circle on the right.



Monoclinic system represented by orthoclase (twinned). Essential symmetry element: one twofold axis.

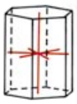


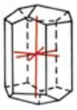
Triclinic system represented by axinite. No axis of symmetry.

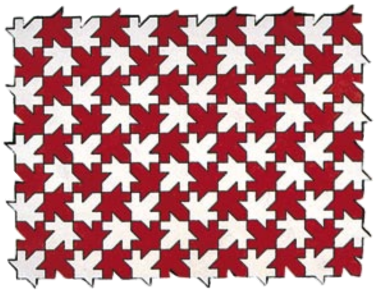
Hexagonal system represented by beryl. Essential symmetry: one sixfold axis.

SAME BUT DIFFERENT
Some crystallographers (studiers of crystals) consider the trigonal system part of the hexagonal system. Both systems have the same set of axes, but the trigonal has only threefold symmetry. This is seen in the terminal faces.

Trigonal system represented by calcite. Essential symmetry: one threefold axis.

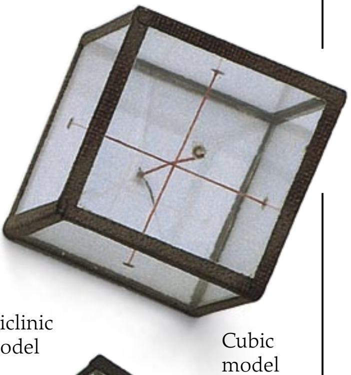




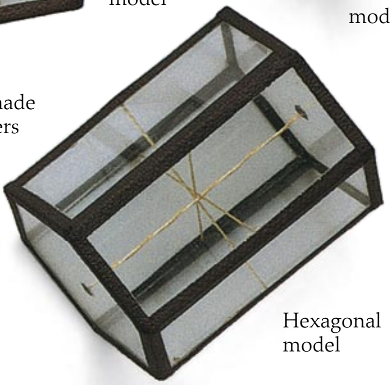


DESIGNED FOR SYMMETRY
This maple leaf design is one of 13 made to commemorate the 13th Congress of the International Union of Crystallography, held in Canada in 1981. The repetitive designs were based on the elements of crystal symmetry.

Triclinic model



Cubic model

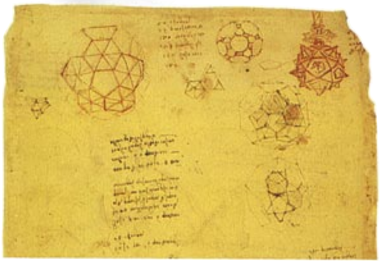


Hexagonal model

MODEL CRYSTALS
Crystal models were made to help crystallographers understand symmetry. These glass models were made in about 1900 in Germany. They contain cotton threads strung between the faces to show axes of rotation.

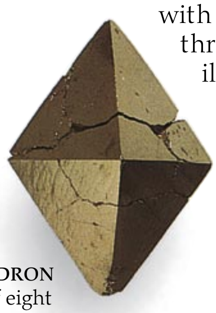
Form

Crystals of the same mineral may not look alike. The same faces on two crystals may be different sizes and therefore form different-shaped crystals. Crystals may also grow with a variation of "form." Shown here are three forms found in the cubic crystal system, illustrated by pyrite.

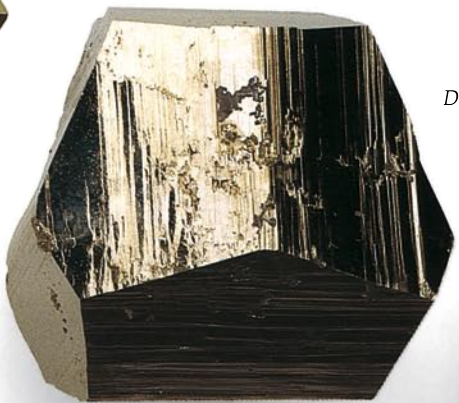


Studies of the transformation of geometrical bodies from Leonardo da Vinci's sketchbook

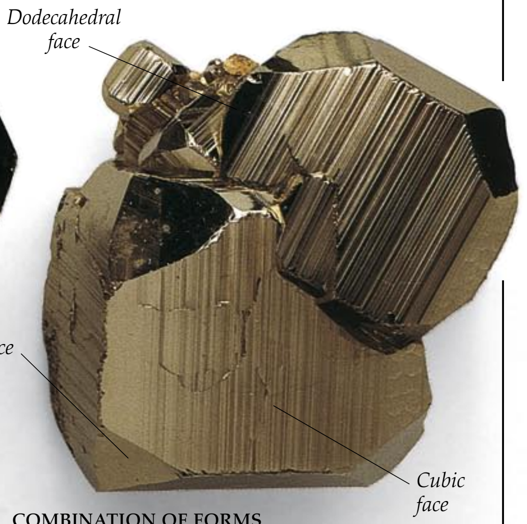
CUBE
A form of six square faces that make 90° angles with each other. Each face intersects one of the fourfold axes and is parallel to the other two.



OCTAHEDRON
A form of eight equilateral triangular faces, each of which intersects all three of the fourfold axes equally.

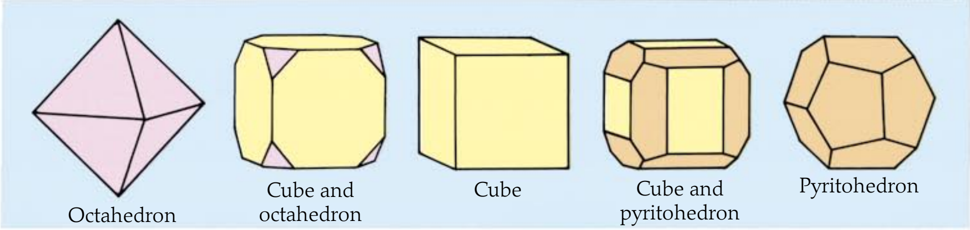


PYRITOHEDRON
This form consists of 12 five-sided faces. It is also known as a pentagonal dodecahedron.



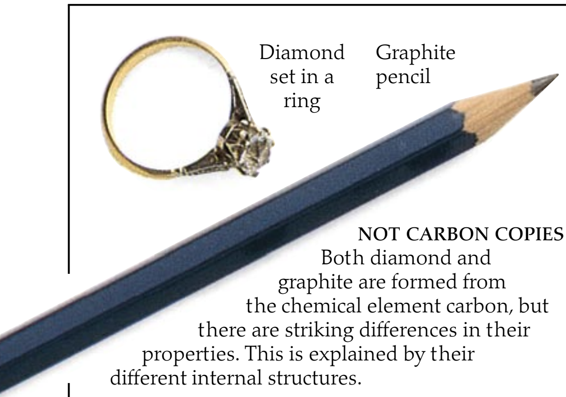
COMBINATION OF FORMS
These crystals show cubic faces combined with octahedral faces with poorly developed dodecahedral faces blending into the cubic faces.

Below: Diagram to show the relationship between different cubic forms

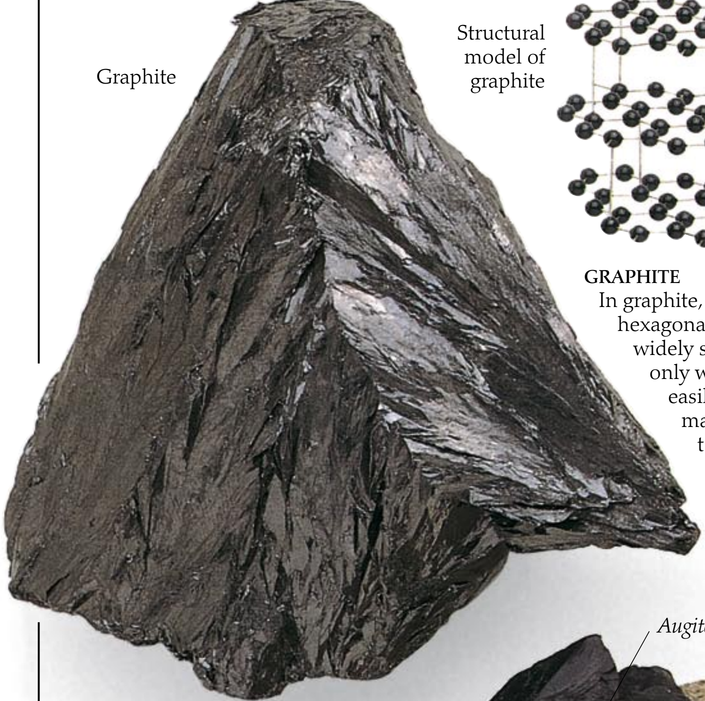


…and inside

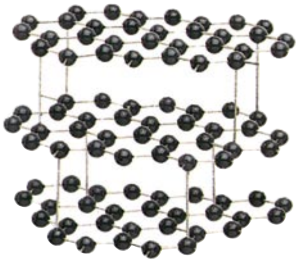
THE INTERNAL ATOMIC STRUCTURE of crystals determines their regular shape and other properties. Each atom has its own special position and is tied to others by bonding forces. The atoms of a particular mineral always group in the same way to form crystals of that mineral. In early crystallography, the study of crystals, one of the most significant deductions was made by R. J. Hauy (p. 15) in 1784. In 1808, English chemist J. Dalton defined his theory that matter was built up from tiny particles called atoms. In 1895, German physicist W. Röntgen discovered X-rays, and in 1912, Laue (p. 15) realized that X-rays might help determine the arrangement of atoms within a solid. This was the start of our understanding of the inside of crystals.



NOT CARBON COPIES
Both diamond and graphite are formed from the chemical element carbon, but there are striking differences in their properties. This is explained by their different internal structures.



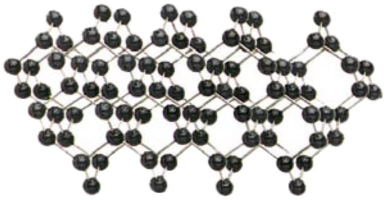
Graphite



Structural model of graphite

GRAPHITE
In graphite, carbon atoms are linked in a hexagonal (six-sided) arrangement in widely spaced layers. The layers are only weakly bonded and can slip easily over one another, making graphite one of the softest minerals.

Diamond crystal

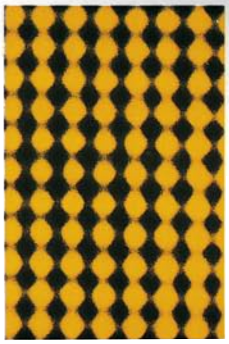


Structural model of diamond

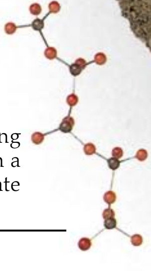
DIAMOND
In diamond, each carbon atom is strongly bonded to four others to form a rigid compact structure. This structure makes diamond much harder than graphite.

Augite crystal

AUGITE
An important group of silicate minerals is the pyroxenes, including augite. Their internal structure is based on a single chain of SiO_4 tetrahedra.

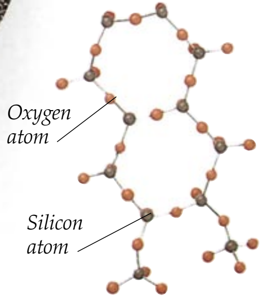


GOLD ATOMS
Crystalline solids have a complex latticework of atoms. This photograph shows the atomic lattice of gold magnified millions of times. Each yellow blob represents an individual atom.



Model showing SiO_4 tetrahedra in a single-chain silicate

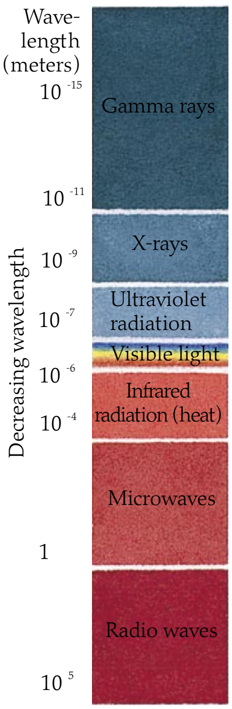
ACTINOLITE
Silicate minerals, present in all common rocks apart from limestone, have a basic unit of a tetrahedron (four faces) of one silicon and four oxygen atoms (SiO_4). Actinolite, a member of a group of minerals known as amphiboles, has a structure based on a double chain of these tetrahedra.



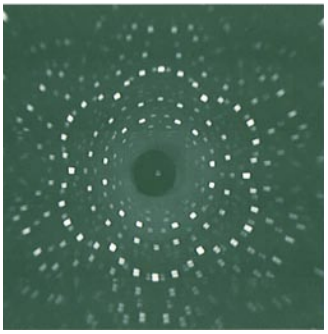
Model showing SiO_4 tetrahedra in a double-chain silicate

BERYL
In some silicate minerals, the internal structure is based on groups of three, four, or six SiO_4 tetrahedra linked in rings. Beryl (pp. 38–39) has rings made of groups of six tetrahedra.

MAX VON LAUE (1879–1960)
Laue showed with X-ray photographs that crystals were probably made of planes of atoms.



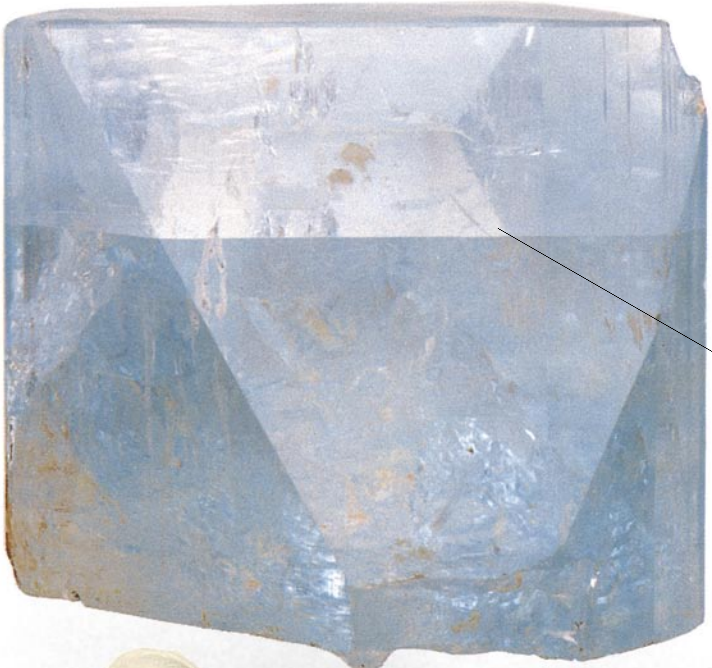
ELECTRO-MAGNETIC WAVES
X-rays are part of the electromagnetic radiation spectrum. All radiations can be described in terms of waves, many of which, such as light, radio, and heat, are familiar. The waves differ only in length and frequency. White light, which is visible to the human eye, is composed of electromagnetic waves varying in wavelength between red and violet in the spectrum (p. 16), but these visible rays are only a fraction of the whole spectrum.



X-RAY PHOTO
This Laue photograph shows the diffraction, or splitting up, of a beam of X-rays by a beryl crystal. The symmetrical pattern is related to the hexagonal symmetry of the crystal.

Cleavage

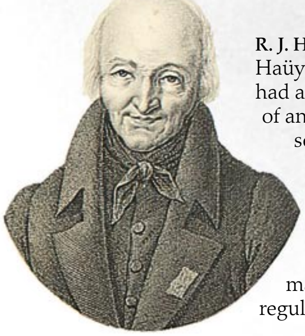
Some crystals split along well-defined planes called cleavage planes which are characteristic for all specimens of that species. Cleavage forms along the weakest plane in the structure and is direct evidence of the orderly arrangement of atoms.



TOPAZ
This fine blue topaz crystal from Madagascar shows a perfect cleavage. Topaz is one of a group of silicates with isolated SiO_4 groups in their structure.

Thin cleavage flakes

MICA
The micas are a group of silicate minerals which have a sheet structure. The atomic bonding perpendicular (at right angles) to the sheet structure is weak, and cleavage occurs easily along these planes.



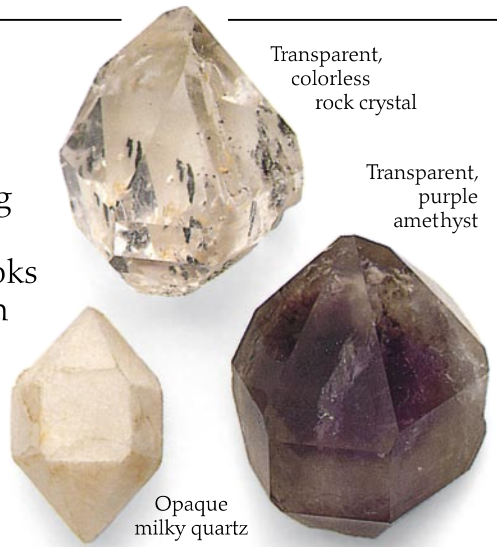
R. J. HAÜY (1743–1822)
Haüy realized that crystals had a regular shape because of an inner regularity. He had seen how calcite often fractures along cleavage planes into smaller diamond shapes (rhombs) and decided crystals were built up by many of these small, regularly stacked blocks.

QUARTZ
The structure of quartz is based on a strongly bonded, three-dimensional network of silicon and oxygen atoms. Crystals do not cleave easily but show a rounded, concentric fracture known as conchoidal.

The color of crystals

The color of a crystal can be its most striking feature. The causes of color are varied, and many minerals occur in a range of colors. Something looks a particular color largely due to your eye and brain reacting to different wavelengths of light (p. 15). When white light (daylight) falls on a crystal, some of the wavelengths may be reflected, and some absorbed. If some are absorbed, those remaining will make up a color other than white because some of the wavelengths that make up white light are missing. Sometimes light is absorbed and re-emitted without changing and the mineral will appear colorless.

MOONSTONES
The most familiar gem variety of the feldspar minerals is moonstone (p. 45). The white or blue sheen is caused by layers of tiny crystals of albite within orthoclase.

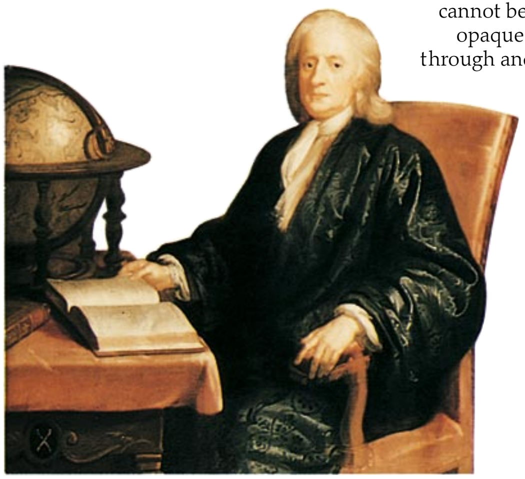


Transparent, colorless rock crystal
Transparent, purple amethyst
Opaque milky quartz

SEE-THROUGH OR OPAQUE
Crystals can be transparent (they let through nearly all the light and can be seen through), translucent (they let some light through but cannot be seen through clearly), or opaque (they do not let any light through and cannot be seen through at all). Most gemstones are transparent but can be colored or colorless.

Idiochromatic

Some minerals are nearly always the same color because certain light-absorbing atoms are an essential part of their crystal structure. These minerals are described as idiochromatic. For example, copper minerals are nearly always red, green, or blue according to the nature of the copper present.



ISAAC NEWTON (1642–1727)
Sir Isaac Newton was an English scientist who achieved great fame for his work on, among other things, the nature of white light. He discovered that white light can be separated into seven different colors, and followed this with an explanation of the theory of the rainbow.

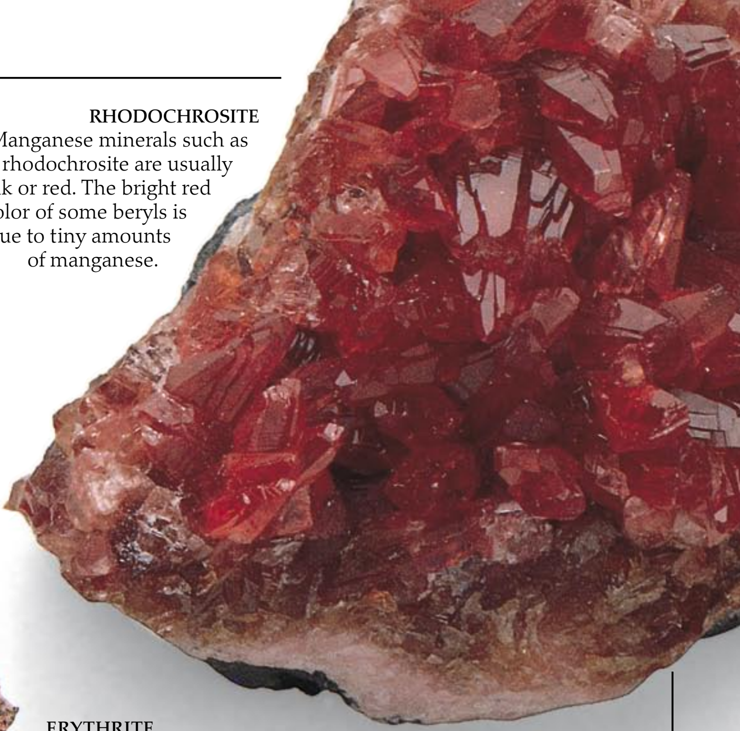
The colors known as the spectrum, produced by dispersion (scattering) of white light in a prism

SULFUR
Sulfur is an idiochromatic mineral and normally crystallizes in bright yellow crystals. These are often found as encrusting masses around volcanic vents and fumaroles (p. 20).

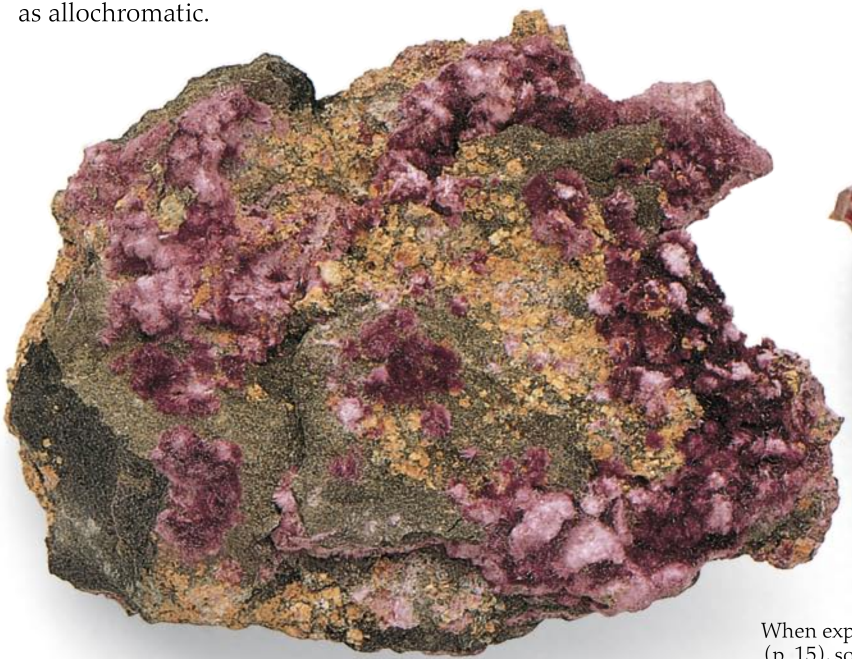
AZURITE
Azurite is a copper mineral which is always a shade of blue – hence the term azure blue. In ancient times it was crushed and used as a pigment.

Allochromatic

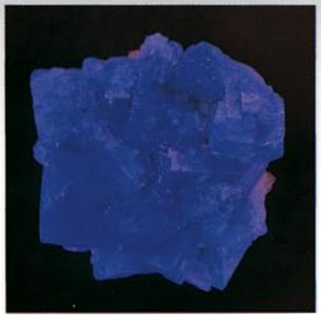
A large number of minerals occur in a wide range of colors caused by impurities or light-absorbing defects in the atomic structure. For example, quartz, diamond, beryl, and corundum can be red, green, yellow, and blue. These minerals are described as allochromatic.



RHODOCHROSITE
Manganese minerals such as rhodochrosite are usually pink or red. The bright red color of some beryls is due to tiny amounts of manganese.



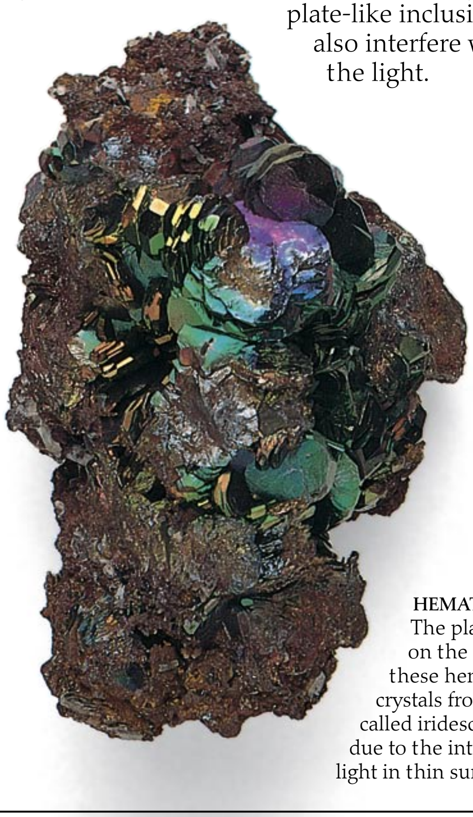
ERYTHRITE
Cobalt minerals such as erythrite are usually pink or reddish. Trace amounts of cobalt may color normally colorless minerals.



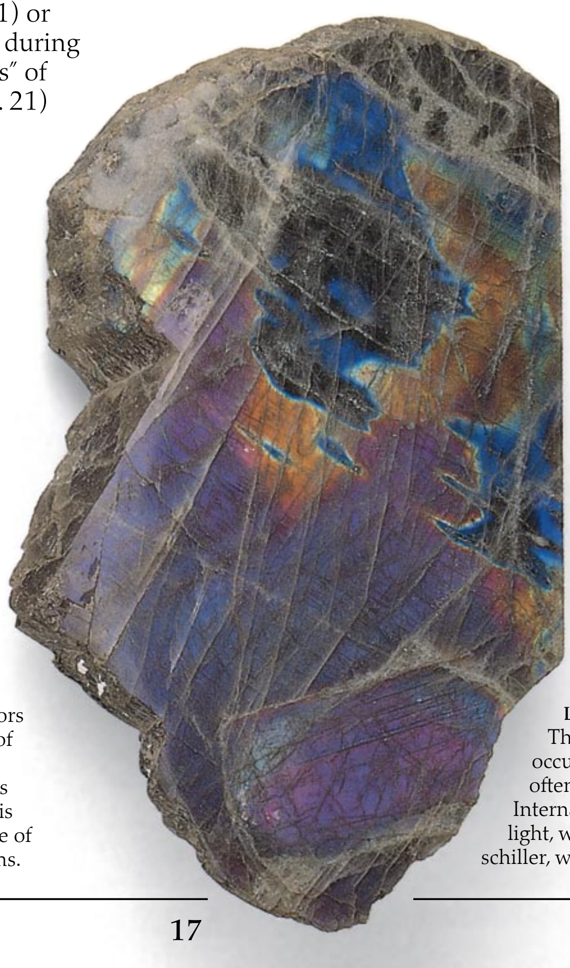
FLUORITE
When exposed to invisible ultraviolet light (p. 15), some minerals emit visible light of various colors. This is called fluorescence, usually caused by foreign atoms called activators in the crystal structure. The fluorescent color of a mineral is usually different from its color in daylight. This fluorite crystal is green in daylight.

Play of colors

The color in some minerals is really a play of colors like that seen in an oil slick or a soap bubble. This may be produced when the light is affected by the physical structure of the crystals, such as twinning (p. 21) or cleavage planes (p. 15), or by the development during growth of thin films. Microscopic "intergrowths" of plate-like inclusions (p. 21) also interfere with the light.



HEMATITE
The play of colors on the surface of these hematite crystals from Elba is called iridescence. It is due to the interference of light in thin surface films.



LABRADORITE
The feldspar mineral labradorite can occur as yellowish crystals, but more often it forms dull gray crystalline masses. Internal twinning causes interference of light, which gives the mineral a sheen, or schiller, with patches of different colors.

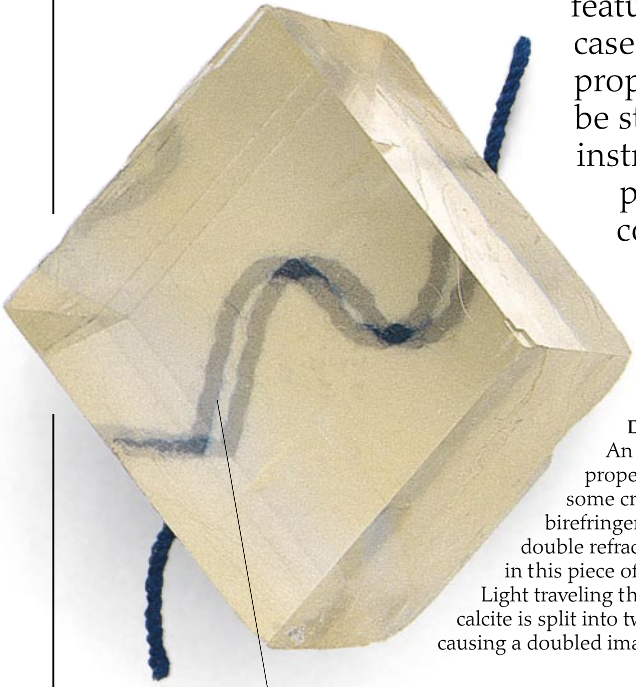
SALT
A space in the atomic structure of a crystal, caused by a missing atom, can form a color center. Coloration of common salt is thought to be caused by this.

Identification

Sherlock Holmes, the fictional master of criminal investigation and identification, looks for vital clues with the help of a hound

"What is it?" This is the first question to ask about a mineral, crystal, or gemstone. In order to identify a crystal it is necessary to test its properties. Most minerals have fixed or well-defined chemical compositions and a clearly identifiable crystal structure (pp. 14–15). These give the mineral a characteristic set of physical properties. Color (pp. 16–17), habit (pp. 22–23), cleavage (p. 15), and surface features can be studied using a hand lens, but in most cases this is not enough for positive identification. Other properties such as hardness and specific gravity (SG) can be studied using basic equipment, but more complex instruments are needed to fully investigate optical properties, atomic structure, and chemical composition.

SPOT THE DIFFERENCE
These two gemstones look almost identical in color, yet they are two different minerals: a yellow topaz (*left*), and a citrine (*right*).

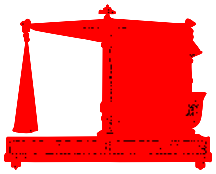


SEEING DOUBLE
An important property of some crystals is birefringence, or double refraction, as in this piece of calcite. Light traveling through the calcite is split into two rays, causing a doubled image.

Doubled image of wool seen through calcite

Orthoclase
SG = 2.6
Galena
SG = 7.4

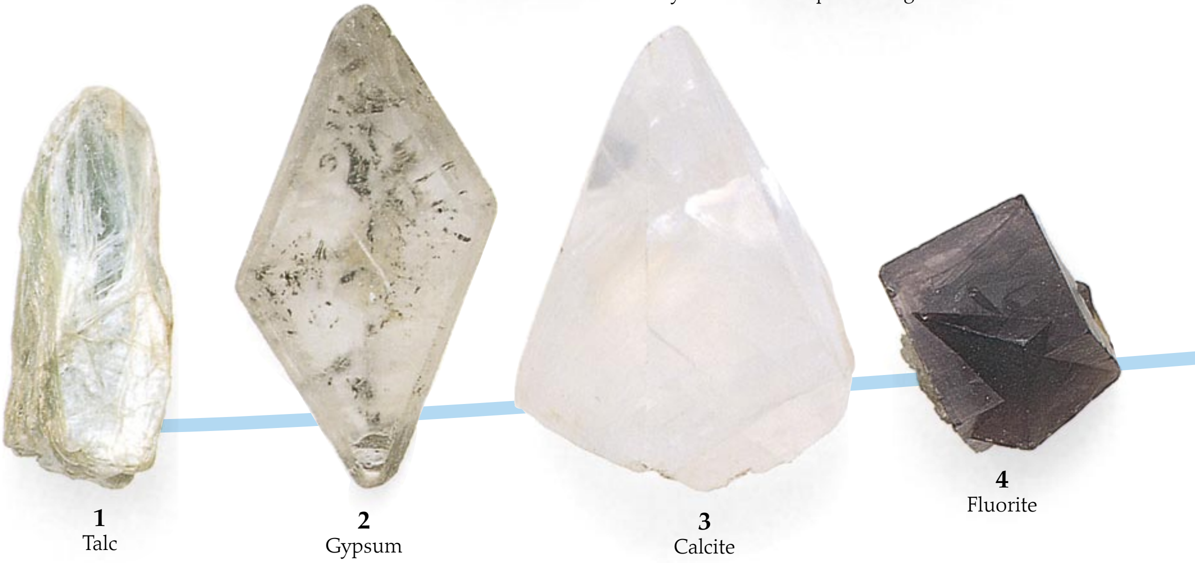
WEIGHING IT UP
Specific gravity is a basic property. It is defined as the ratio of the weight of a substance compared to that of an equal volume of water If W1 = weight of specimen in air, and W2 = its weight in water, then W1 divided by W1-W2 = SG. The two crystals shown are of similar size but their SG differs considerably. This reflects the way the atoms are packed together.

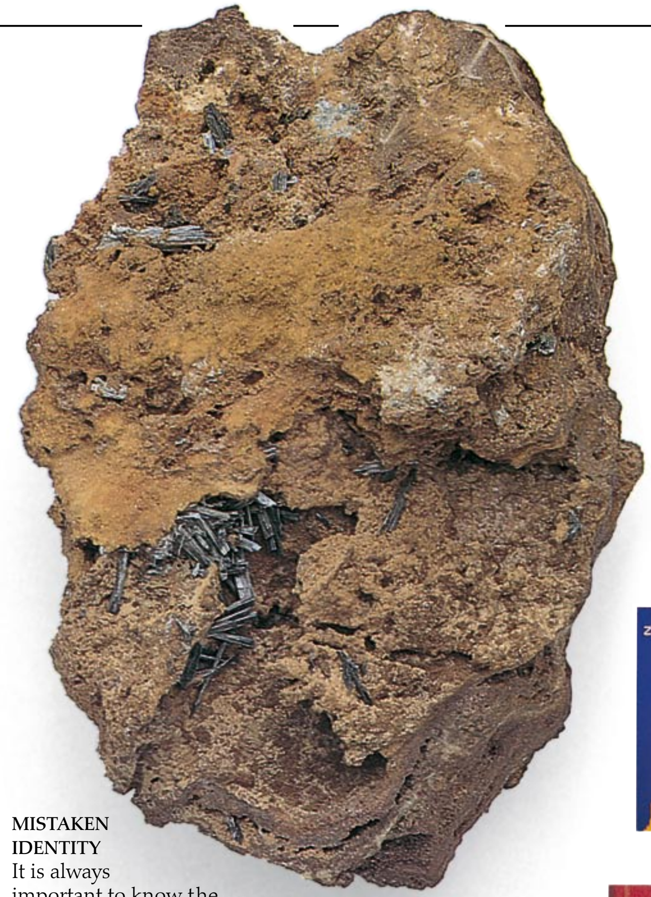


Chemical beam balance being used to determine specific gravity

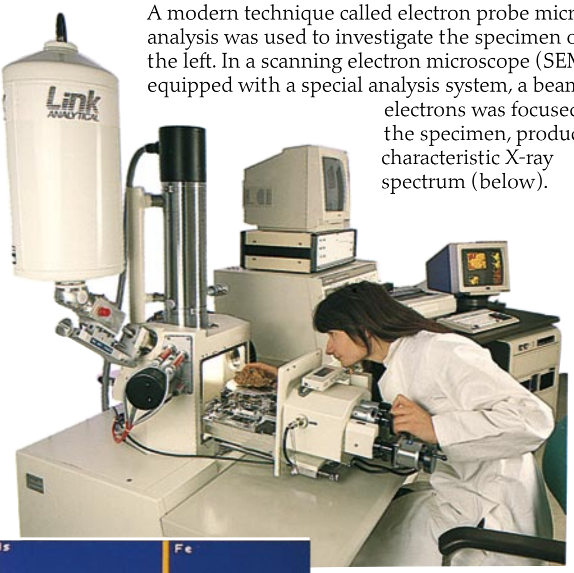
Hardness

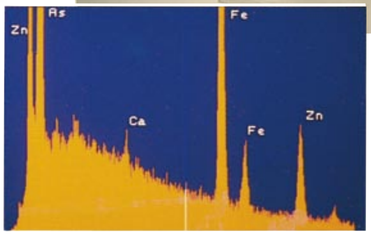
The property of hardness is dependent upon the strength of the forces holding atoms together in a solid. A scale of hardness on which all minerals can be placed was devised by F. Mohs in 1822. He selected 10 minerals as standards and arranged them in order of hardness so that one mineral could scratch only those below it on the scale. Intervals of hardness between the standard minerals are roughly equal except for that between corundum (9) and diamond (10).





PROBING ABOUT
A modern technique called electron probe microanalysis was used to investigate the specimen on the left. In a scanning electron microscope (SEM) equipped with a special analysis system, a beam of electrons was focused on the specimen, producing a characteristic X-ray spectrum (below).

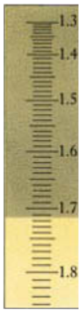




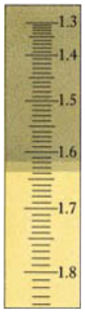
The X-ray spectrum showing large peaks for iron (Fe), arsenic (As), calcium (Ca), and zinc (Zn)

10
Diamond

MISTAKEN IDENTITY
It is always important to know the chemical composition of a crystal or mineral, and modern techniques can reveal some surprising results. These small blue-gray crystals on limonite were shown by X-ray methods to be the mineral symplesite (hydrated iron arsenate). However, further analysis showed that they unexpectedly contain some calcium and zinc as well.

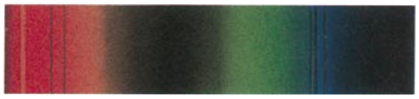


Spinel
RI: 1.71

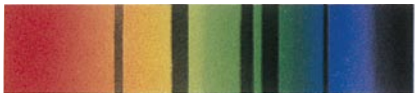


Tourmaline
RI: 1.62 and 1.64

SHADOW PLAY
Refractive index (RI) is a mineral's refracting ability – that is, its ability to bend a beam of light – and is useful in identification. It can be measured, along with birefringence, with a refractometer. A light is made to pass through the stone, and one or two shadow edges form on a scale depending on whether the gem is singly or doubly refractive. The position of the shadow gives the RI.



Ruby colored by chromium



Almandine garnet colored by iron

ABSORBED IN STONE
A spectroscope is often used to distinguish between gemstones of a similar color. Light enters through a slit and separates into its spectrum of colors (p. 16). If a gemstone is put between the light source and the slit, dark bands appear in the spectrum, where wavelengths have been absorbed by the stone.

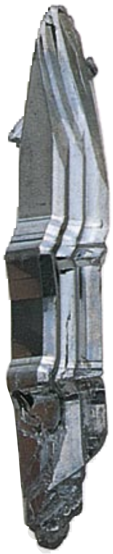
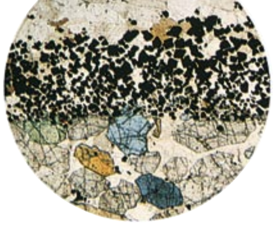
MOHS (1773-1839)
Friedrich Mohs was professor of mineralogy at Graz, and later Vienna, Austria. While at Graz he developed the scale of hardness.

Natural growth

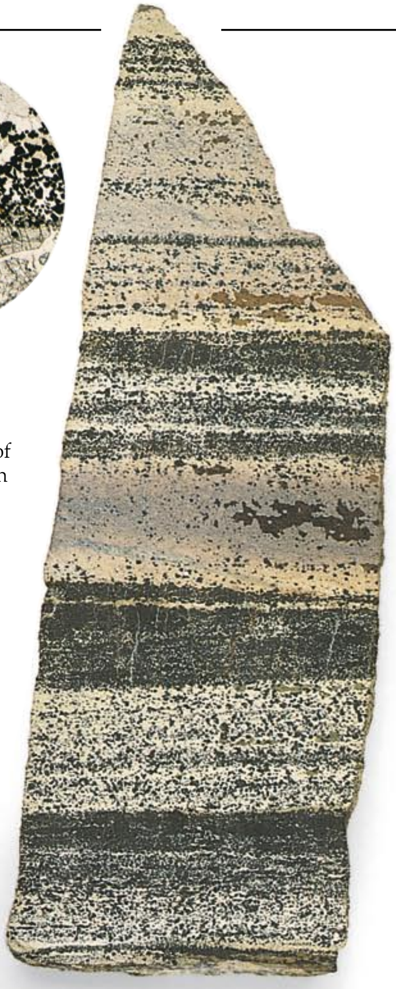
CRYSTALS GROW as atoms arrange themselves, layer by layer, in a regular, three-dimensional network (pp. 14–15). They can form from a gas, liquid, or solid and usually start growing from a center or from a surface. Growth continues by the addition of similar material to the outer surfaces until the supply stops. It is rare to find a perfect crystal. Temperature, pressure, chemical conditions, and the amount of space all affect growth. It is estimated that in an hour, millions and millions of atoms arrange themselves layer by layer across a crystal face. With this number it is not surprising that defects occur.



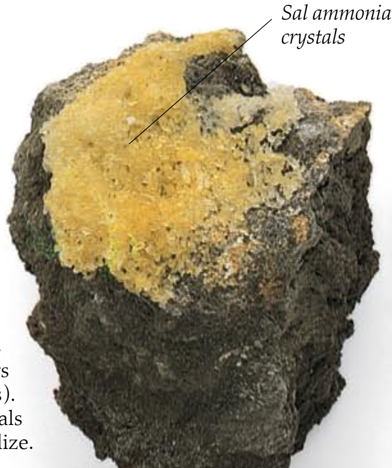
TWISTED AROUND
Crystals can be bent or twisted like this stibnite. This may be because they were bent by some outside force during growth.



CRYSTAL LAYERS
This magnified image, called a photomicrograph, shows the layers of different crystals in a thin section of magmatic rock.

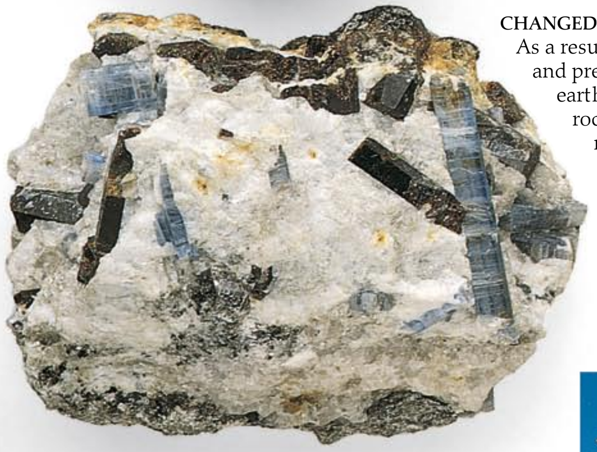


SETTLING DOWN
As magma (the molten rock below the earth's surface) cools, so crystals of various minerals form. Some magmatic rock forms in layers, as different rock-forming minerals settle and crystallize at different times.

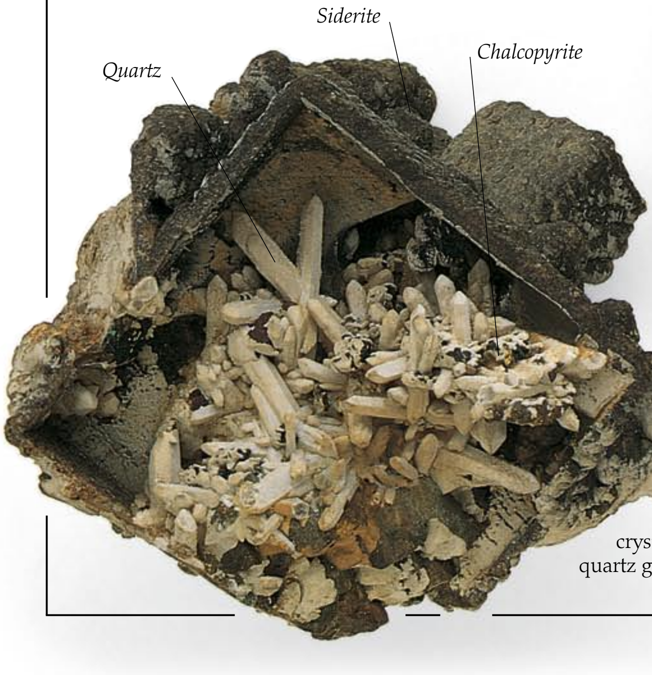


MINERAL SPRINGS
Hot watery solutions and gases containing minerals, such as sal ammoniac (ammonium chloride), sometimes reach the earth's surface through hot springs and fumaroles (gas vents). Here, the minerals may crystallize.

IN THE POCKET
Holes in rocks often provide space in which crystals can grow. Cavities containing fine gemquality crystals are known as gem pockets. This gem pocket at Mt. Mica, Maine, was discovered in 1979.

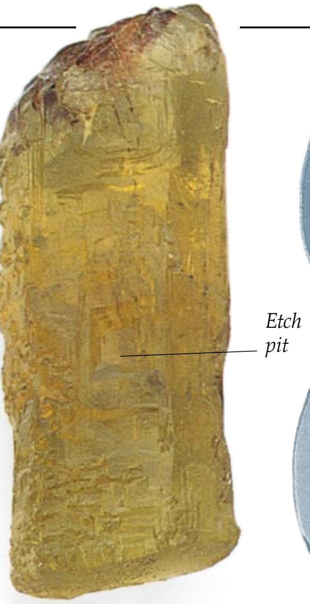


CHANGED BY FORCE
As a result of the high temperatures and pressures deep within the earth's crust, minerals in solid rock can recrystallize, and new minerals form. This process is known as metamorphism. The blue kyanite and brown staurolite crystals in this specimen have been formed in this way.

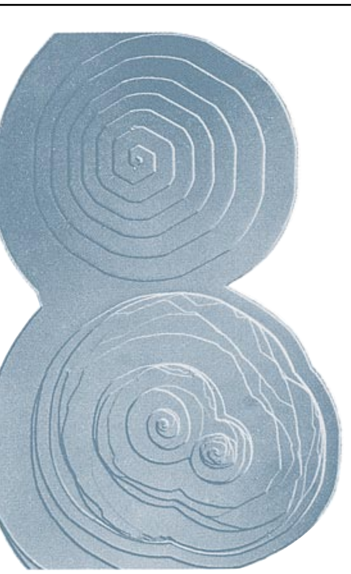


TAKING SHAPE
Many minerals crystallize from watery solutions. We only see the final product but can often work out a sequence of events. In this specimen, a fluorite crystal grew first, and was coated with siderite. The fluorite was later dissolved and removed, but the coating of siderite kept the characteristic cubic shape of the fluorite crystal. Lastly, crystals of chalcopyrite and quartz grew inside the hollow cube.

BUILDING BLOCKS
Skyscrapers are built in a similar way to crystals – by adding layer upon layer to the same symmetrical shape.



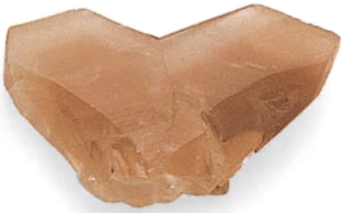
BERYL ETCHING
Solutions or hot gases may dissolve the surface of certain crystals after growth, as in this beryl. Regularly shaped hollows known as etch pits are formed. Their shape is related to the internal atomic structure.



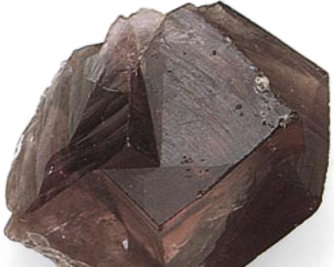
SPIRALING AROUND
Crystal faces are rarely flat, due to a variety of growth defects. This magnified image of the surface of a crystal shows the atoms forming a continuous spiral, instead of layers across the crystal face.

Twinning

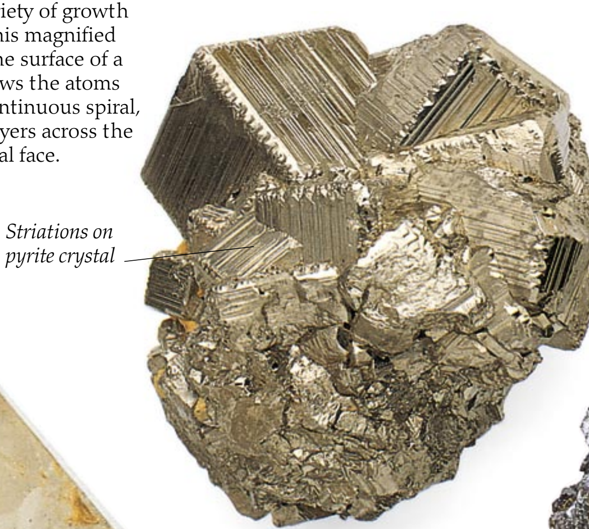
During crystallization, two crystals of the same mineral may develop in such a way that they are joined at a common crystallographic plane. Such crystals are known as twinned crystals. The apparent line of contact between the two parts is known as the twin plane.



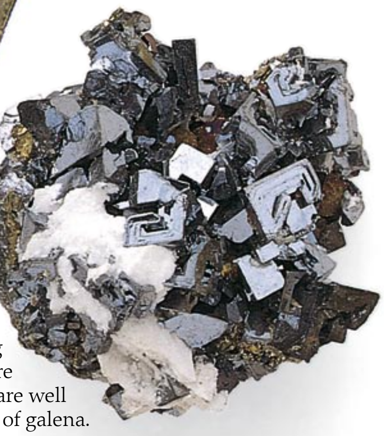
BUTTERFLY TWINS
This simple type of twin is known as a butterfly contact twin crystal because of its resemblance to butterfly wings. This example is calcite.



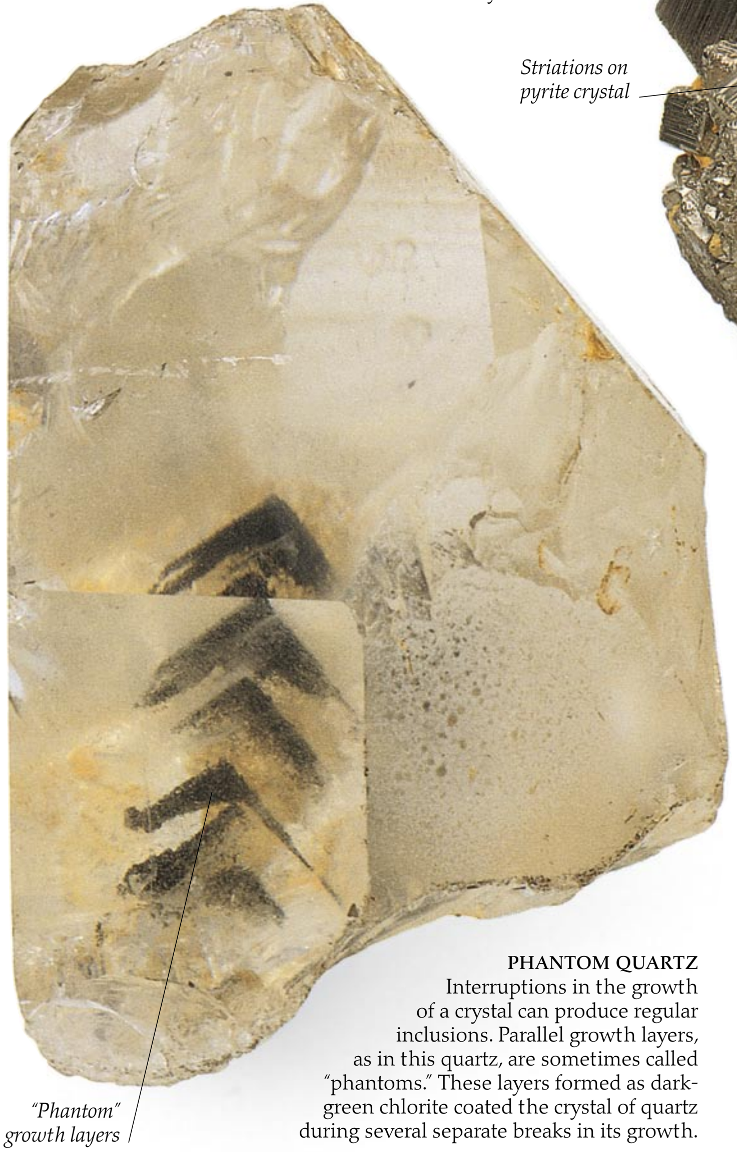
GROWING UP TOGETHER
When the two parts of twin crystals grow into each other, they are known as penetration twins. The example shown is a twin of purple fluorite.



FORM COMPETITION
Many crystals have parallel lines called striations running along or across their faces. These are usually caused when two forms (p. 13) try to grow at the same time.

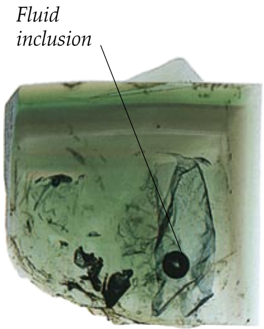


AT THE HOP
Some crystals tend to build up more quickly along the edges of the faces than at the centers, producing cavities in the faces. These are known as hopper crystals and are well illustrated here by crystals of galena.

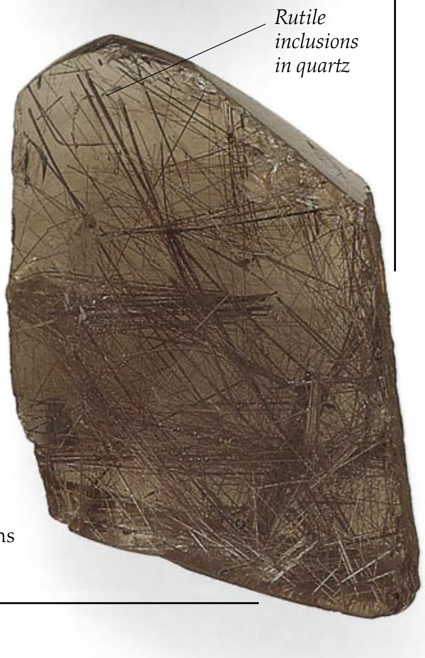


PHANTOM QUARTZ
Interruptions in the growth of a crystal can produce regular inclusions. Parallel growth layers, as in this quartz, are sometimes called "phantoms." These layers formed as dark-green chlorite coated the crystal of quartz during several separate breaks in its growth.

CRYSTAL ENCLOSURE
During growth, a crystal may enclose crystals of other minerals, commonly hematite, chlorite, and tourmaline. These are known as inclusions.

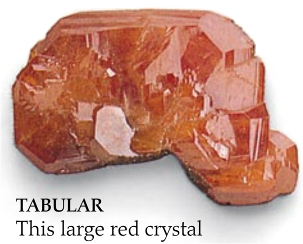


A fluorite crystal containing inclusions of ancient mineral-forming fluids

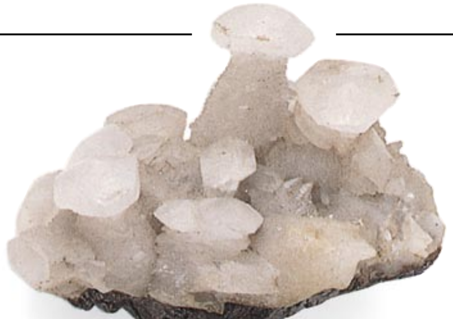


Good habits

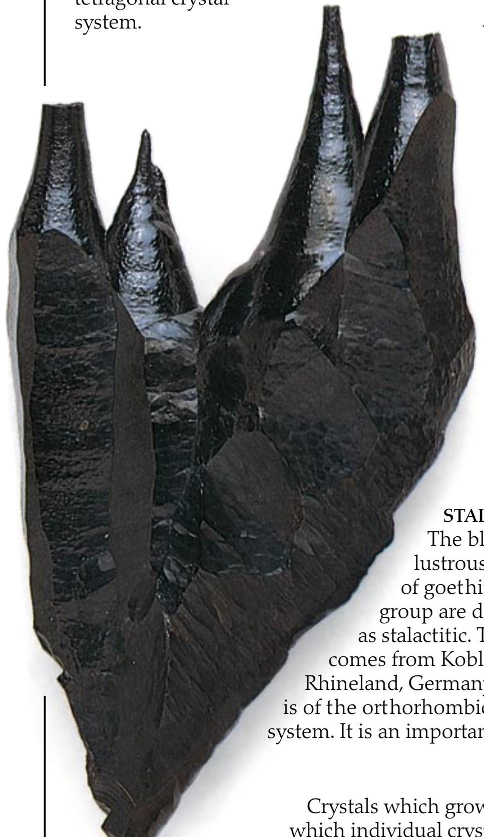
The general shape of crystals is called their habit and is an important part of crystallography. Crystal habit is useful in identification and in well-formed crystals may be so characteristic of a particular mineral that no other feature is needed to identify it. The forms (p. 13) or group of forms that are developed by an individual crystal are often what give it a particular habit. As crystals grow, some faces develop more than others, and it is their relative sizes that create different shapes. Most minerals tend to occur in groups of many crystals rather than as single crystals and rarely show fine crystal shapes. These are called aggregates.



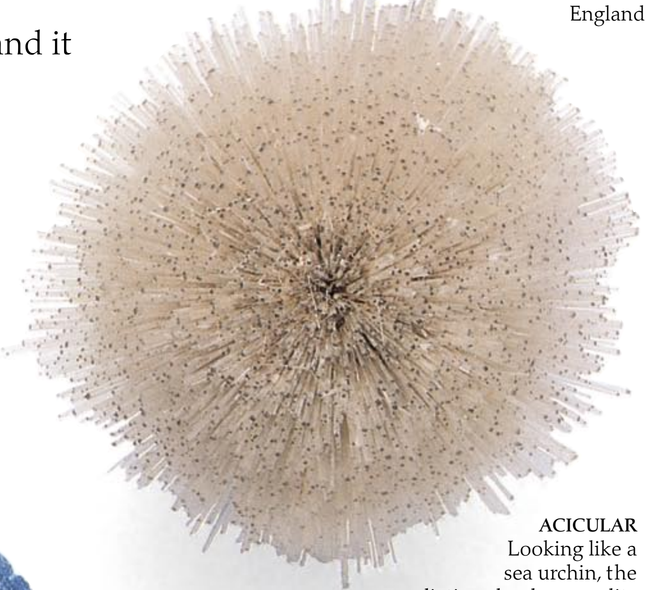
TABULAR
This large red crystal of wulfenite comes from the Red Cloud mine in Arizona. Its habit is known as tabular. Such crystals are often extremely thin. Wulfenite belongs to the tetragonal crystal system.



TWO FORMS
These "mushrooms" show two forms of calcite crystals: The "stems" are scalenohedrons and have eight of twelve triangular faces. The "caps" are formed by rhombohedra in parallel position. This group comes from Cumbria, England.

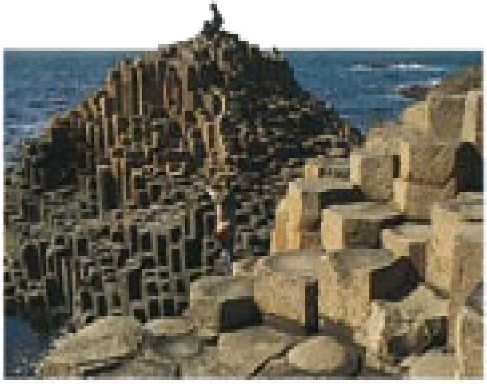


STALACTITIC
The black, lustrous aggregates of goethite in this group are described as stalactitic. The group comes from Koblenz, Rhineland, Germany. Goethite is of the orthorhombic crystal system. It is an important iron ore.

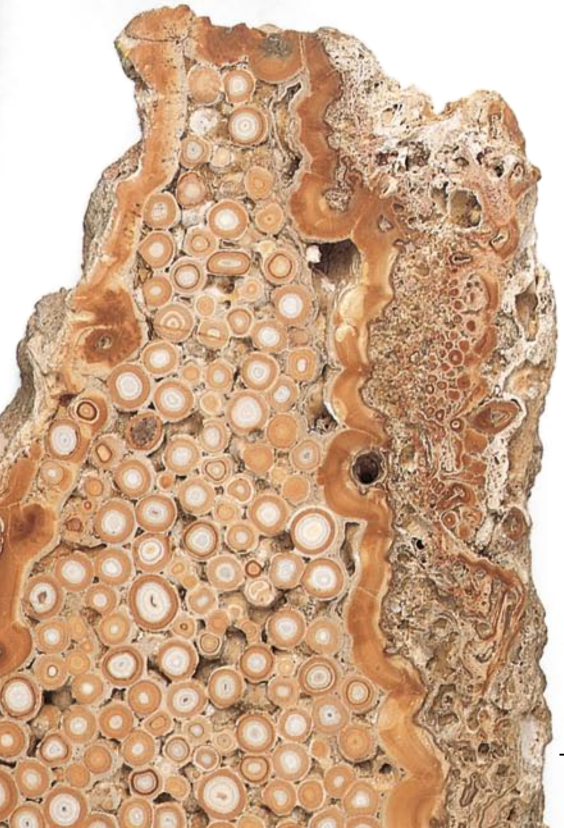


ACICULAR
Looking like a sea urchin, the radiating slender mesolite crystals in this aggregate are described as acicular, meaning needle-like. They are very fragile and, like needles, can pierce your skin. This group comes from Bombay, India.

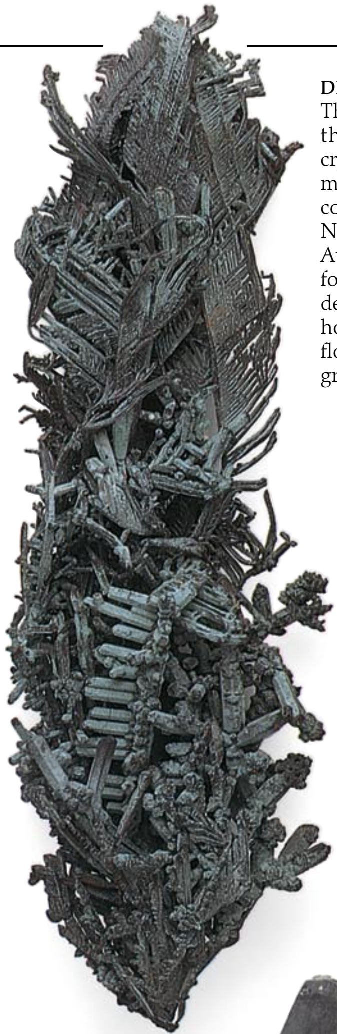
MASSIVE
Crystals which grow in a mass, in which individual crystals cannot be clearly seen, are described as massive. Dumortierite is a rare mineral which is usually massive like this piece from Bahia, Brazil.



CRYSTAL-SHAPED
The Giant's Causeway near Portrush in County Antrim, Northern Ireland, looks like a collection of hexagonal crystals. However, the phenomenon is not crystal growth but jointing due to contraction as the basaltic lava cooled.

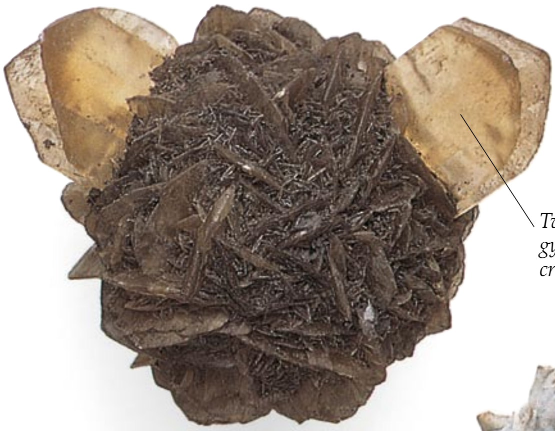


PISOLITIC
This polished slab of limestone from Czechoslovakia is described as pisolitic. Pisolites are round pea-sized aggregates of crystals built of concentric layers, in this case of calcium carbonate.



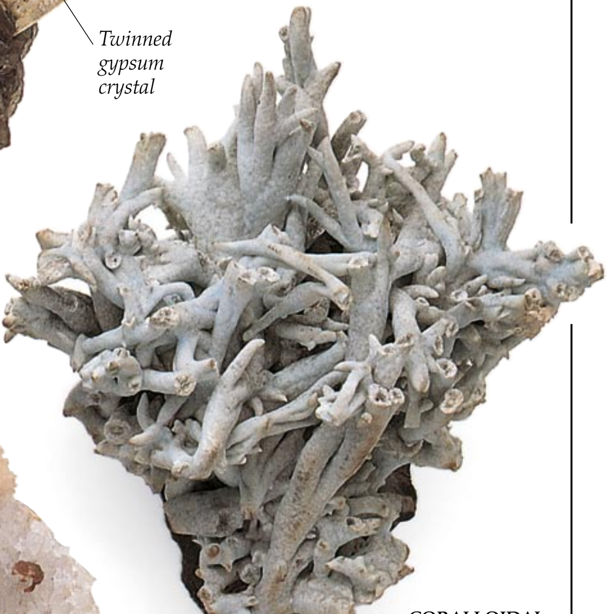
DENDRITIC
The term used to describe the habit of these copper crystals is dendritic, meaning tree-like. They come from Broken Hill, New South Wales, Australia. Copper often forms in hydrothermal deposits (p. 24), filling holes in some basaltic lava flows, but is also found as grains in sandstones.

PRISMATIC
Beryl crystals are mostly found in granite pegmatites (p. 25) and can grow to be very large. Those illustrated are prismatic – they are longer in one direction than the other. They were found in 1930 in a quarry in Maine and were over 30 ft (9 m) long.



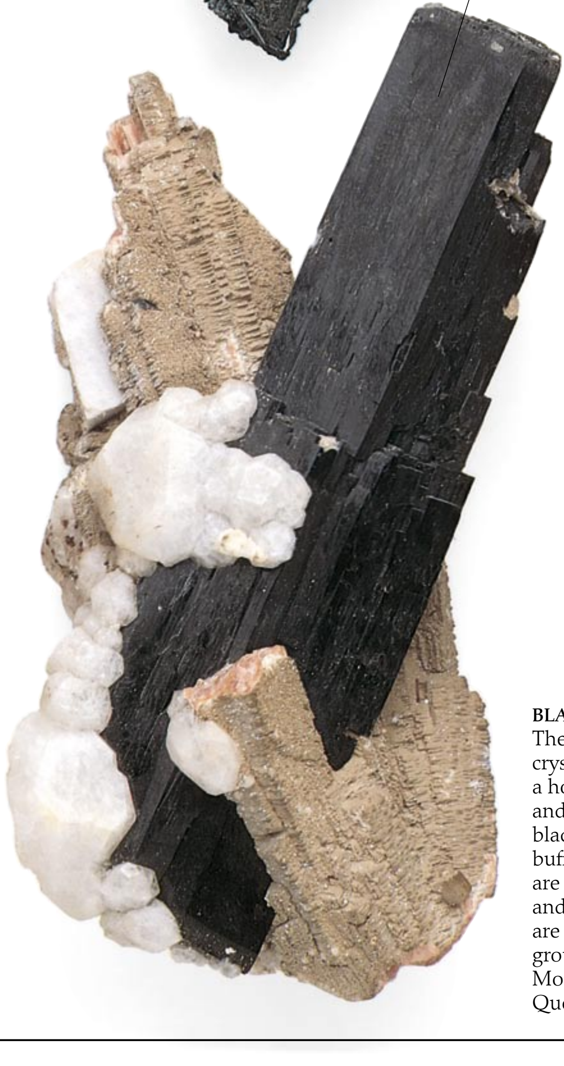
Twinned gypsum crystal

LENTICULAR
Twinned (p. 21) clear crystals of gypsum form the "ears" on this mass of lenticular crystals from Winnipeg, Canada. Lenticular means shaped like a lentil or lens, from the Latin *lenticula*, a lentil.

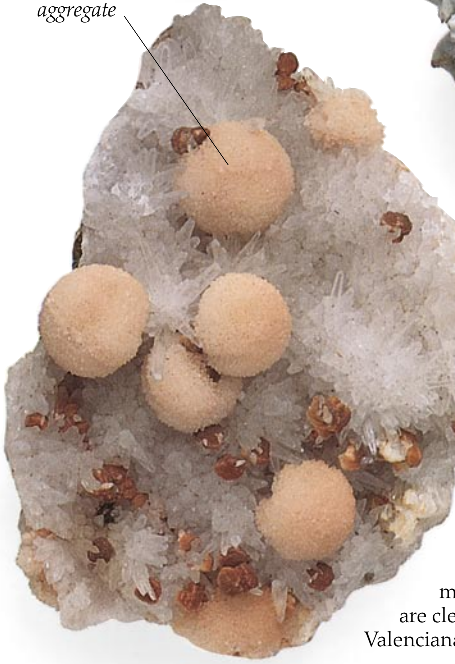


CORALLOIDAL
Aggregated crystals that look like coral are said to have a coralloidal habit. This mass of pale-green aragonite crystals came from Eisenberg, Styria, Austria.

Bladed hornblende crystal



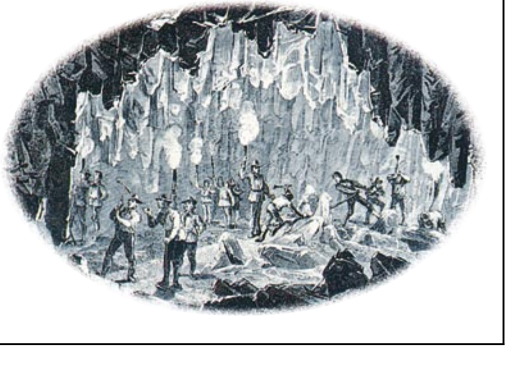
Globular caldite crystal aggregate



GLOBULAR
These aggregated crystals of calcite look a bit like scoops of ice cream and are described as globular, meaning spherical. The other crystals are clear quartz, and the group came from Valenciana mine, Guanajuato, Mexico.

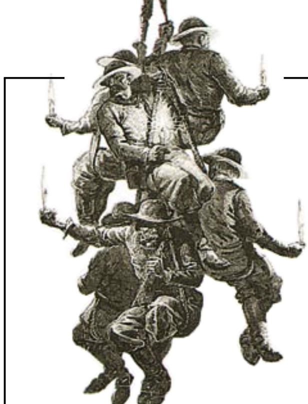
BLADED
The prismatic black crystal in this group is a hornblende crystal and an example of a bladed crystal. The buff-colored crystals are prismatic serandite and the white crystals are analcime. The group was found at Mont-St.-Hilaire, Quebec, Canada.

QUARTZ IN A CAVE
Crystal growth is influenced by the physical and chemical conditions at the time. Many good crystals grow in cavities which can vary in size from small potato stones (p. 7) to huge caves, as shown in this 19th-century impression of a quartz grotto.

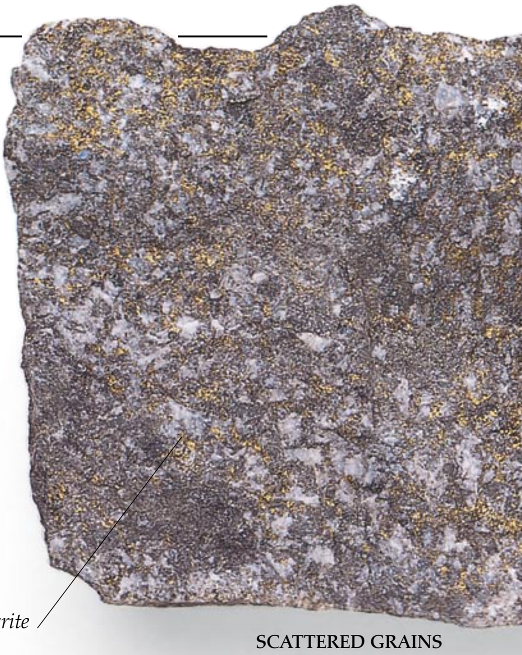


Discovery – recovery

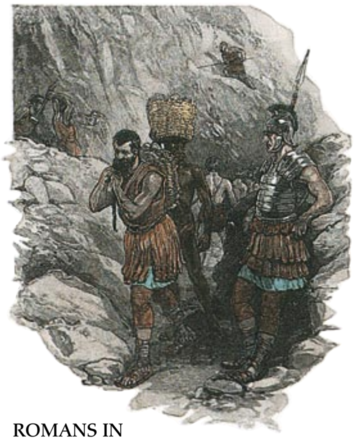
The search for mineral deposits including metals and gemstones has been going on since prehistoric times. Some minerals, such as copper, occur in great quantity; others, such as silver, gold, and diamond, are found in much smaller quantities but fetch higher prices. If mining is to be profitable, large quantities of the mineral must occur in one area and be relatively easy to extract, either by surface quarrying, panning, or dredging, or, if necessary, by deep mining. Minerals from which useful metals such as copper, iron, and tin are extracted are called ores.



19th-century engraving or miners descending the shaft at Wieliczka salt mine, Poland



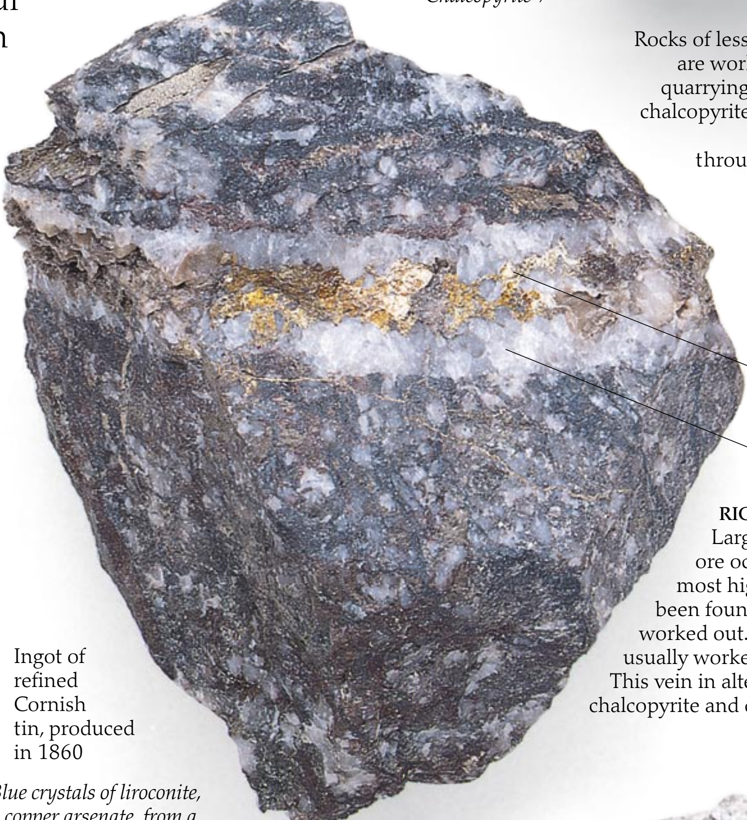
SCATTERED GRAINS
Rocks of less than one percent ore are worked today by open-pit quarrying. The ore, such as this chalcopyrite copper ore, occurs as small grains scattered through the rock body. The whole rock has to be worked, a huge amount of gangue, or waste, is produced, and an enormous hole is left.



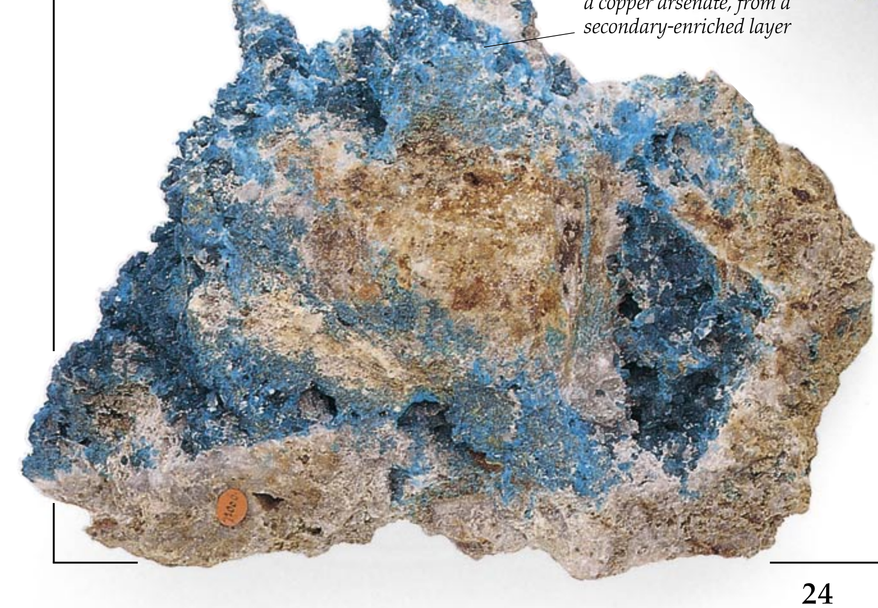
ROMANS IN CORNWALL
The Romans knew of the rich tin deposits in Cornwall, England. Mining techniques have improved since then, but the ore still has to be crushed and separated from the gangue minerals and then refined.

R.K.MICHELL
& Co
MARAZION
REFINED

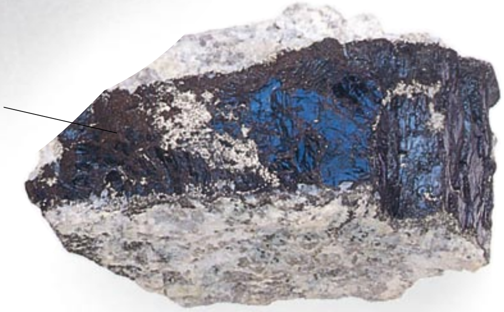
Ingot of refined Cornish tin, produced in 1860



RICH VEIN
Larger concentrations of ore occur in veins, but most high-grade ores have been found and in many cases worked out. Ores in veins are usually worked by deep mining. This vein in altered granite contains chalcopyrite and quartz.



Blue crystals of liroconite, a copper arsenate, from a secondary-enriched layer

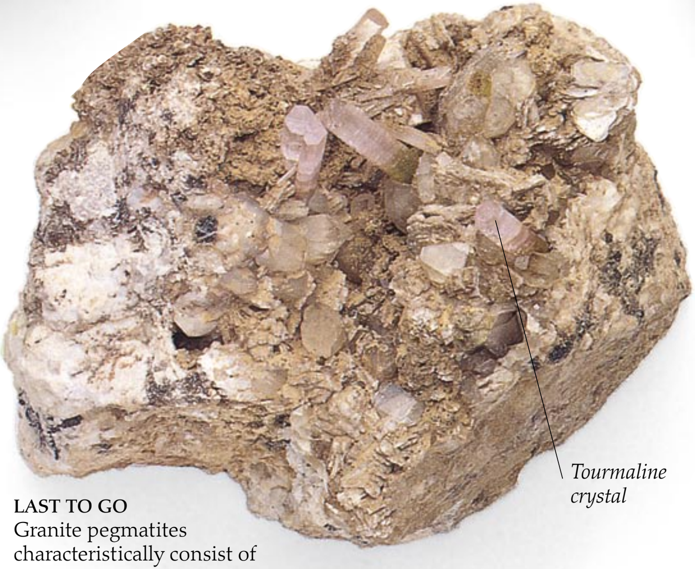


Vein of covellite, a copper sulfide, from a secondary sulfide enrichment layer

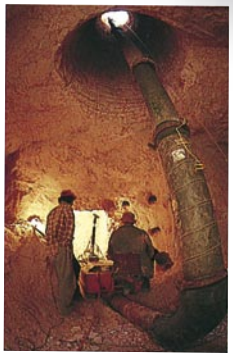
GRADUAL IMPROVEMENT
The natural process of "secondary alteration and enrichment" can improve relatively low-grade ores to higher concentrations. Groundwaters filter down through the upper layers of rock and carry elements downward. These are redeposited in lower layers which are thus enriched. Enriched layers in copper deposits may contain azurite, malachite, and sometimes liroconite, or sulfide minerals such as bornite, chalcocite, and covellite.

SWIRLING WATERS
Panning is a simple method of separating minerals. Light gangue minerals are washed away by the swirling action of water in a metal or wood pan, leaving the wanted minerals behind. This technique is often used to sort out gem-rich river gravels in areas such as Myanmar (formerly Burma) and Thailand.

Panning for gold in the Irrawaddy River, Myanmar. The prospector looks for the glint of gold grains within the waste.

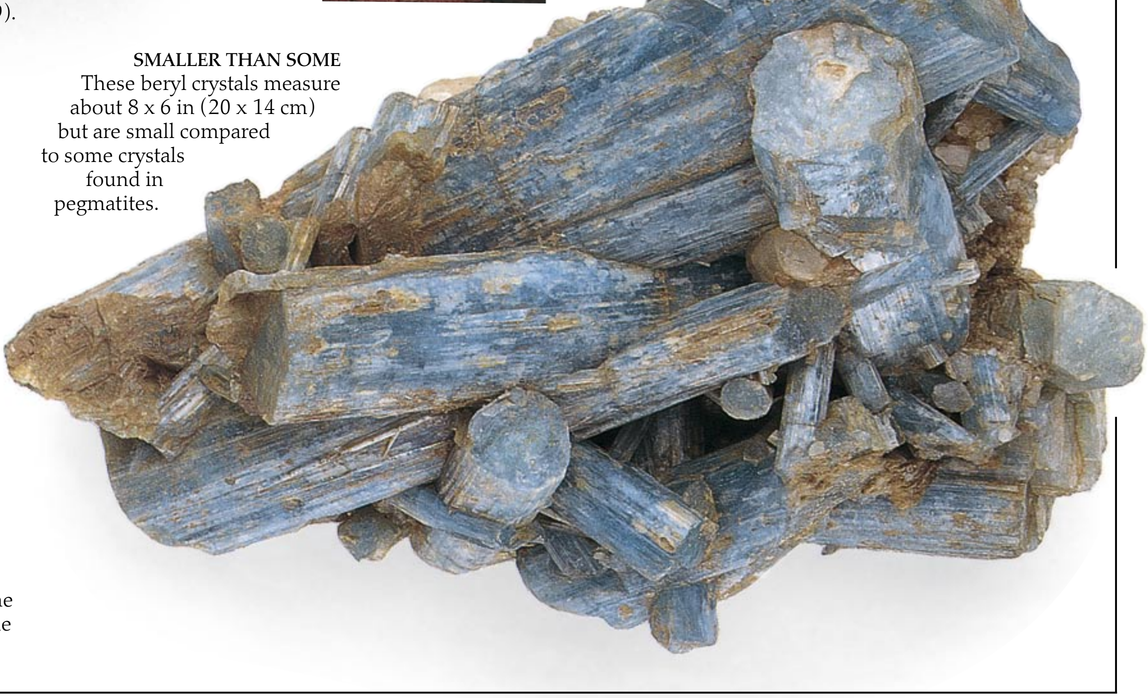


LAST TO GO
Granite pegmatites characteristically consist of large crystals and are the source of many fine gems, including tourmaline (p. 43), topaz (p. 42), and beryl (pp. 38–39). They are formed by the crystallization of the last fluids left after most of the granite has solidified.



DOWN UNDER
Much mining activity takes place underground. This is the Coober Pedy opal mine in South Australia – a source of fine white opals (pp. 40–41).

SMALLER THAN SOME
These beryl crystals measure about 8 x 6 in (20 x 14 cm) but are small compared to some crystals found in pegmatites.



ON THE SURFACE
The Argyle mine in Western Australia is the largest diamond producer in the world. The diamonds are mined by surface-quarrying.

MELTDOWN
Natural bismuth does occur, but artificial crystal groups, like this one, are often produced by melting and then cooling the metal. Bismuth is used in solders, electric fuses, and pigments.

Growing from seed

SCIENTISTS HAVE TRIED TO MAKE CRYSTALS like those found in the earth's crust for well over a century. Natural crystals often contain impurities or are flawed in some way (pp. 20–21), but synthetic ones can be made flawless. They can also be made to grow a particular shape and size for specific needs. In recent times a range of artificial crystals has become important to modern technology. Grown crystals are built into almost every electronic or optical device made today. The need for a huge amount of perfect crystals has led to more and more synthetic crystals being made, and it could be said that future developments in electronics will depend on the development of crystal-growing techniques.

DRAWN OUT
Pure silicon does not occur naturally, so crystals are made artificially for a variety of uses (p. 28). Quartz sand is heated to produce nearly pure silicon. In one process a seed crystal on the end of a rotating rod is dipped into the melt and slowly removed; this is known as "drawing a crystal."

IN A FLUX
Many emeralds are produced by the flux-fusion technique. A powder made of the components of emerald is heated in a crucible with a solid known as a flux. The flux melts, the powder dissolves, and the mixture is left to cool and form crystals. This method is extremely slow. It takes several months for a crystal to grow.

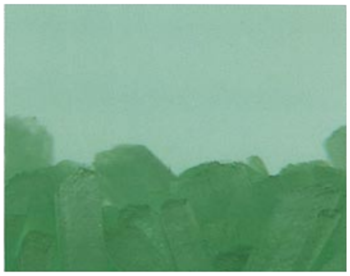
Cut synthetic emerald

Synthetic emerald crystal

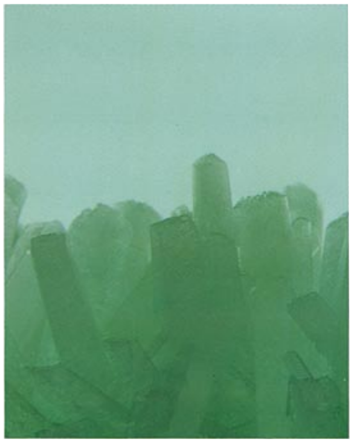
VOYAGE OF DISCOVERY
Crystal growing is important enough for experiments to be done in space. Here, astronaut George Nelson is photographing a protein-crystal-growth experiment on board the space shuttle *Discovery* in 1988.

Melt technique

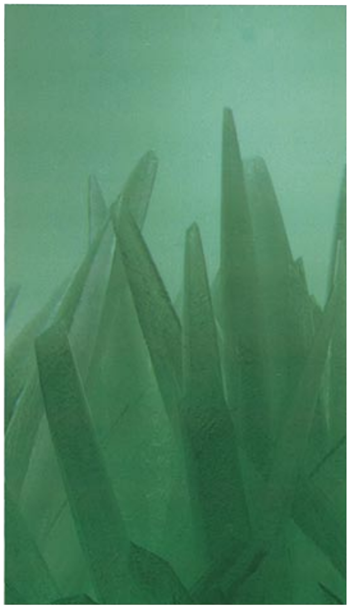
Excellent crystals may be grown by slow cooling or evaporation of a supersaturated solution (no more will dissolve) of a salt such as halite, alum, or ammonium dihydrogen phosphate (ADP). In the experiment shown, powdered ADP containing a small chrome-alum impurity has been completely dissolved in boiling water and then cooled.



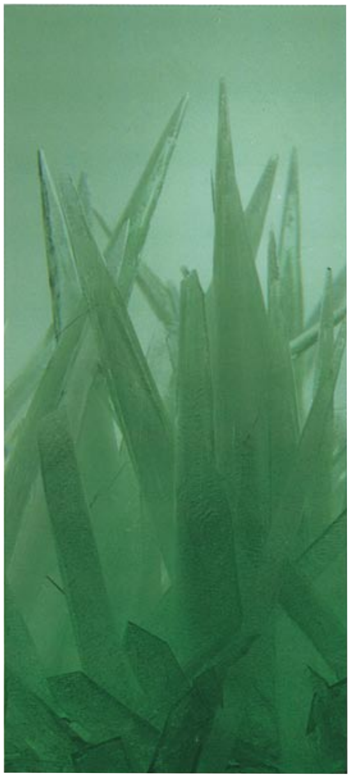
The liquid cools rapidly. Stubby, cloudy prismatic (p. 23) crystals form.



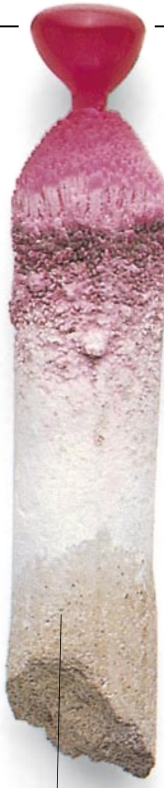
The crystals grow more slowly, allowing them to become clearer.



At room temperature, crystals still grow slowly due to evaporation.



Cooling stops, but evaporation continues. The crystals slowly grow.

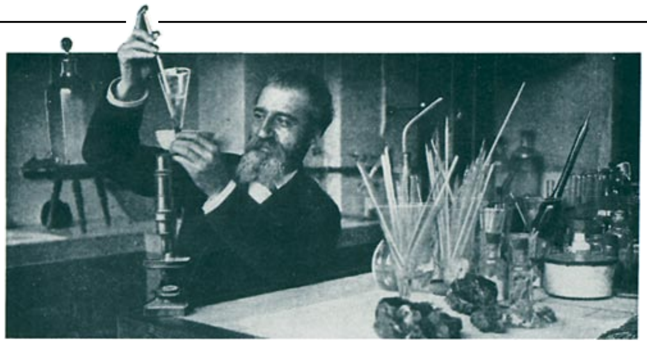


FIRE BOULES
The flame-fusion technique was pefected by French mineral expert A. Verneuil in about 1900. It is used to make spinel (p. 46), rutile (p. 57), and corundum (pp. 36–37). Powdered material is fed through a flame to fuse into liquid drops which drip onto a support. By gradually pulling the support from the heat, a single crystal, or boule, is formed.

Support for growing crystal

Synthetic sapphire boule

Two halves of synthetic ruby boule

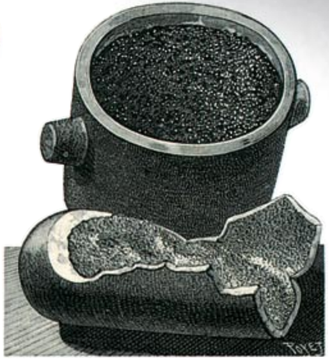


HENRI MOISSAN (1852-1907)
French chemist Henri Moissan tried to produce artificial diamonds in iron crucibles at the Edison workshops in Paris.

EUREKA!
In 1970, the General Electric Company announced the laboratory creation of gem-quality diamonds, two of which are shown here.

Synthetic rubies produced in a crucible

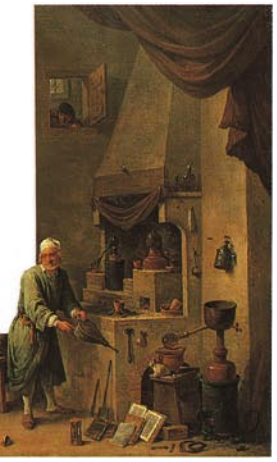
GROWN IN SIZE
The French chemist Frémy was the first to grow gem-quality crystals of a reasonable size, in 1877. He discovered a method of making rubies by melting the necessary materials together and fusing them in a porcelain crucible at very high temperatures.



1890 crucible containing a mass of small gemstones

ABRASIVE CHARACTER
The artificial material carborundum (silicon carbide) is produced by the fusion of coke and sand heated in electrically fired furnaces. It is nearly as hard as diamond – 9.5 on Mohs' hardness scale (pp. 18–19) – and is therefore mostly used as an abrasive.

Hexagonal carborundum crystal

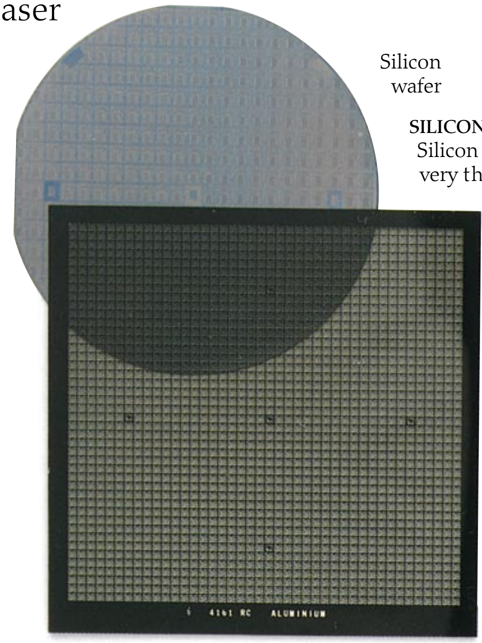


GOLD FEVER
Over the centuries many people have tried to find a way to change nonprecious metals into gold. A complicated process if this detail of *The Alchemist at Work* by David Teniers the Elder (1582-1649) is anything to go by.

Crystals at work

CRYSTALS PLAY AN IMPORTANT PART in this age of rapid technological and social change. Although the basic understanding of crystals was developed before the 20th century, it was only in the latter part of the 20th century that crystal technology became so important. Crystals are now used in control circuits, machines, electronics, communications, industrial tools, and medicine. We also use crystals when shopping – in credit cards. From the crystal laboratory (pp. 26–27) has come the silicon chip, ruby laser rods, and the many forms of diamonds for tools. New crystals are continually being developed for specific purposes.

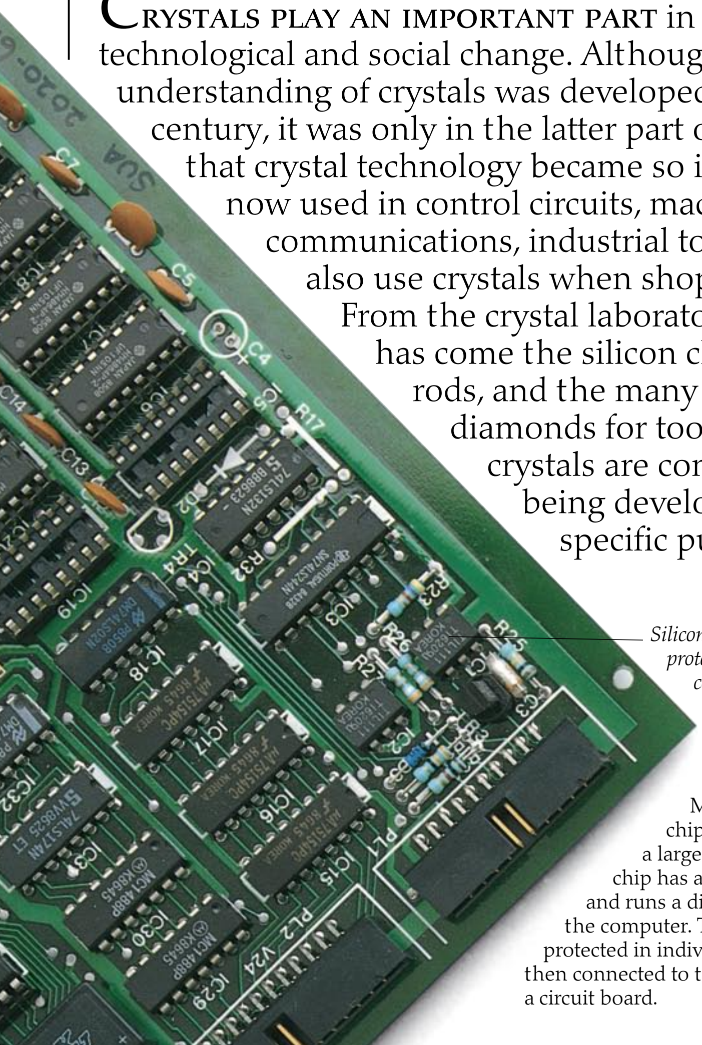
DIAMOND WINDOW
The properties of diamond have led to it being used in space where it has to withstand extreme conditions. Diamond was used in this window for an infrared radiometer experiment on the Pioneer Venus probe. It had to withstand a temperature of 840°F (250°C) near the surface of the planet Venus.



Silicon wafer

SILICON SLICE
Silicon chips are made from very thin slices called wafers cut from artficial crystals of pure silicon (p. 26). The wafers are etched with electronic circuits. one for each chip. The circuit patterns are transferred on to a wafer from a piece of film called a matrix.

Silicon chip matrix

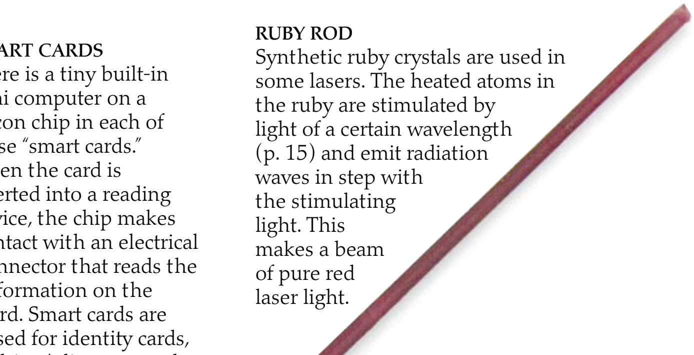


Silicon chip in protective covering

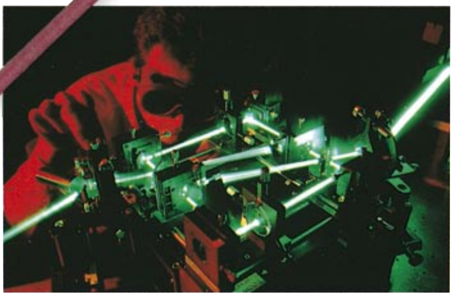
CIRCUIT BOARD
Many different chips are needed in a large computer. Each chip has a different circuit and runs a different part of the computer. The chips are protected in individual cases, then connected to the others on a circuit board.

Location of silicon chip

SMART CARDS
There is a tiny built-in mini computer on a silicon chip in each of these "smart cards." When the card is inserted into a reading device, the chip makes contact with an electrical connector that reads the information on the card. Smart cards are used for identity cards, driver's licenses, and as tickets on public transportation.



RUBY ROD
Synthetic ruby crystals are used in some lasers. The heated atoms in the ruby are stimulated by light of a certain wavelength (p. 15) and emit radiation waves in step with the stimulating light. This makes a beam of pure red laser light.



LASERS
This scientist is experimenting with laser beams. Laser beams can be focused to very small points, generating intense heat. This is put to use in welding, drilling, and surgery.

Diamond tools

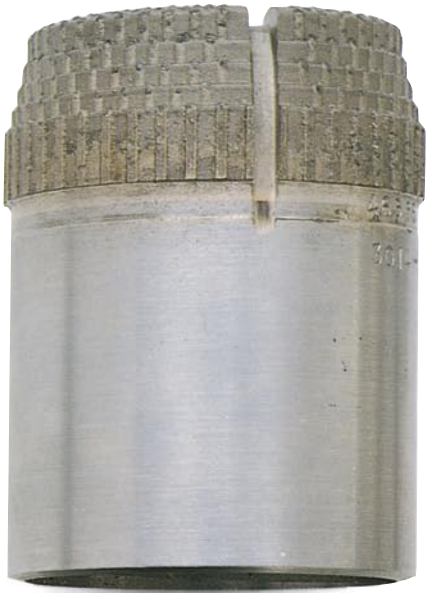
Diamonds are used in a vast number of jobs mainly because they are so hard. They are used in sawing, drilling, grinding, and polishing – from quarrying stone to performing delicate eye surgery – and come in a large range of sizes, shapes, and strengths. Natural and synthetic diamonds are used, but more than 80 percent of industrial diamonds are synthetic.

A surgeon using a diamond-bladed scalpel in delicate eye surgery

DIAMOND SCALPEL
As well as being hard, diamond does not corrode. This property is one reason why diamonds are used in surgery. This surgical scalpel contains a blade made from a natural diamond.

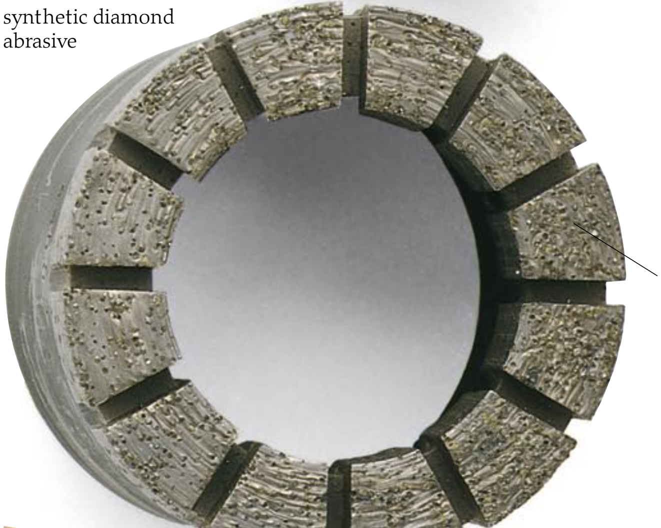
Diamond blade

DRILL BITS
Diamond-tipped drills are used for drilling all types of rock. They are used for drilling oil wells and in prospecting for metals and minerals. Some bits contain diamonds set in the surface. The diamonds are different shapes for different purposes. Other bits are covered with tiny pieces of diamond grit, or abrasive.



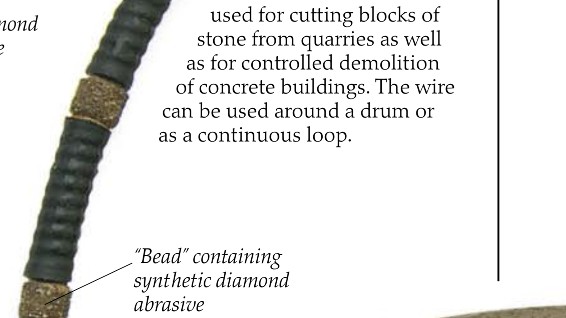
Drill bit containing surface-set natural diamonds

Drill bit covered with synthetic diamond abrasive



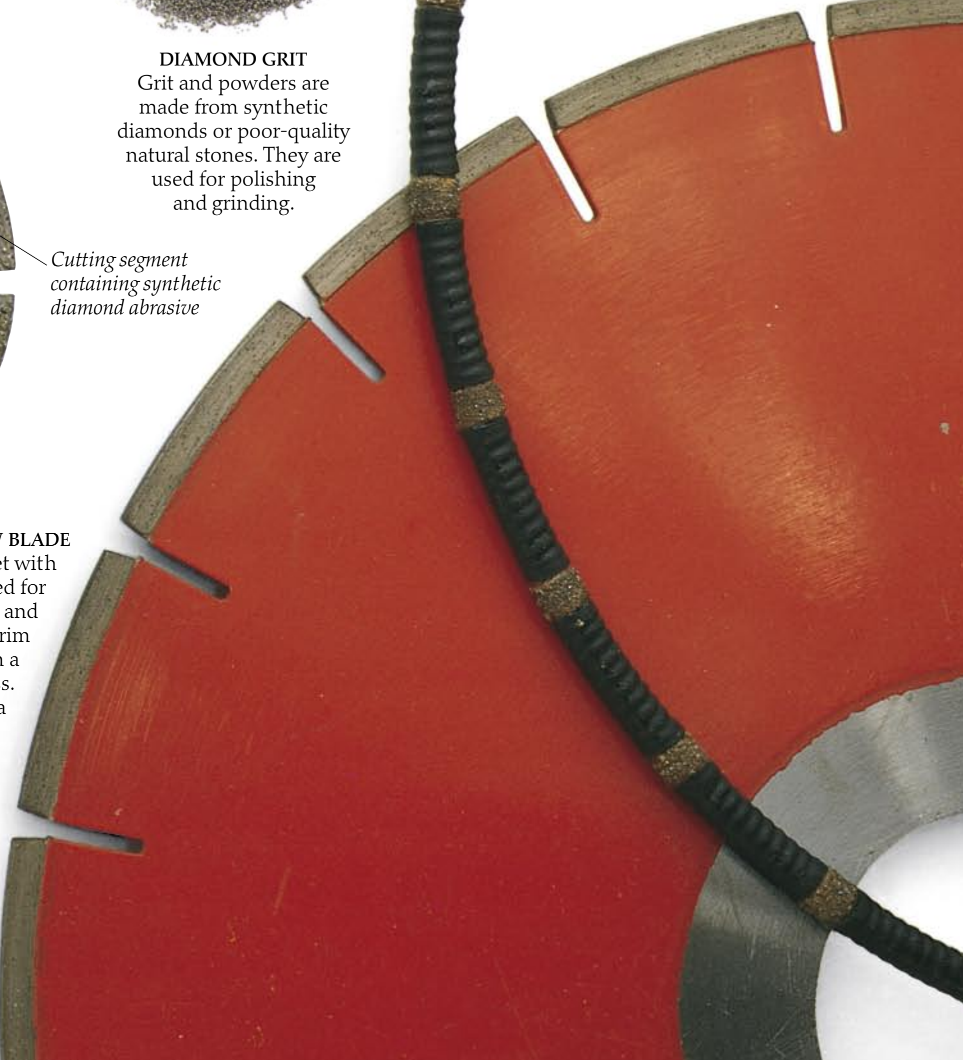
Cutting segment containing synthetic diamond abrasive

DIAMOND GRIT
Grit and powders are made from synthetic diamonds or poor-quality natural stones. They are used for polishing and grinding.



DIAMOND WIRE
Cutting with a diamond wire keeps the loss of material to a minimum. Wires can be used for cutting blocks of stone from quarries as well as for controlled demolition of concrete buildings. The wire can be used around a drum or as a continuous loop.

"Bead" containing synthetic diamond abrasive



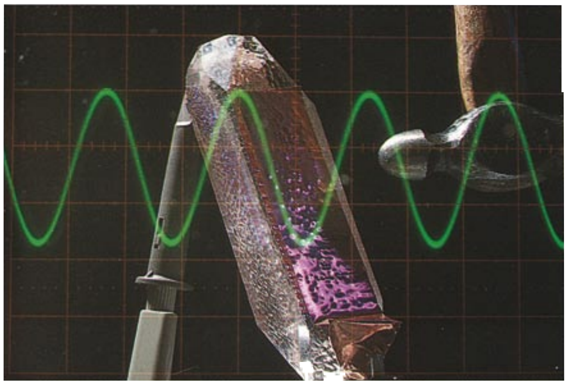
SAW BLADE
Saws set with diamonds are used for cutting glass, ceramics, and rocks. The blades have a rim of industrial diamonds in a "carrier" such as brass. This rim is bonded to a steel disk. As the blade cuts, the carrier wears away rapidly and exposes new diamonds.

Cutting an opening for a window in brickwork using a diamond saw

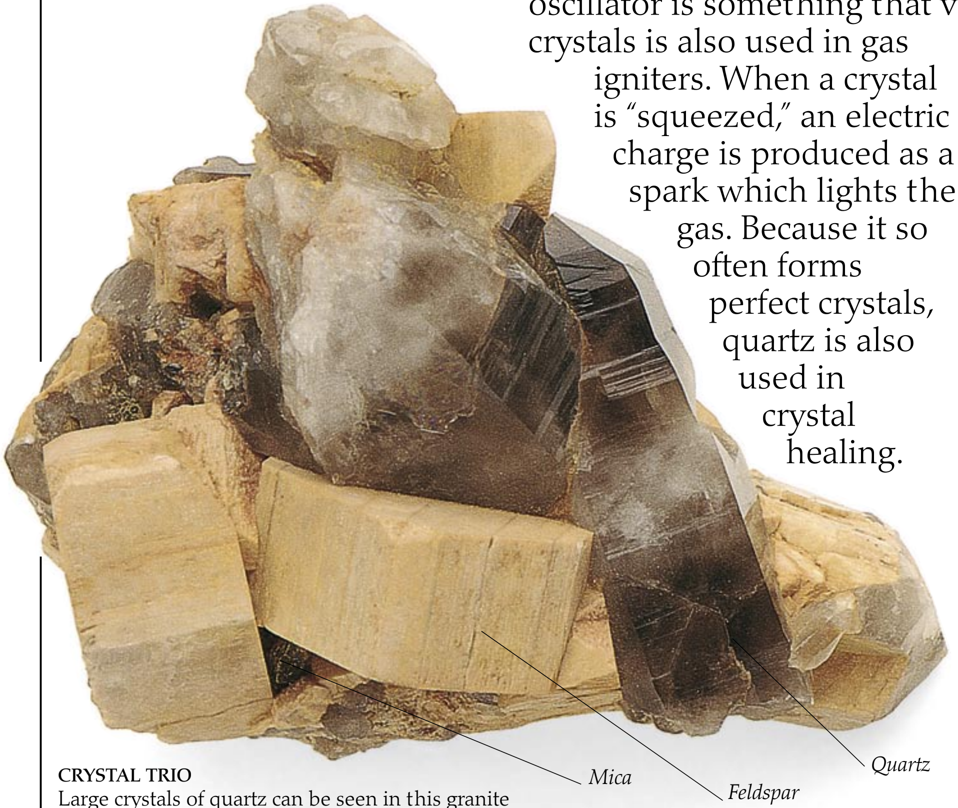
Good vibrations

QUARTZ IS ONE OF THE MOST COMMON MINERALS in the earth's crust. It is widely distributed as veins (p. 24) and is associated with major mineral deposits. It is one of the chief materials in granite and is also the main component of sand and sandstone. As quartzite and sandstone, it is used extensively for building and in the manufacture of glass and ceramics. One of the most interesting properties of quartz crystals is piezoelectricity. This can be used to measure pressure, and quartz crystal oscillators provide fixed, very stable frequency control in radios and televisions (an oscillator is something that vibrates). The piezoelectric effect of crystals is also used in gas igniters. When a crystal is "squeezed," an electric charge is produced as a spark which lights the gas. Because it so often forms perfect crystals, quartz is also used in crystal healing.

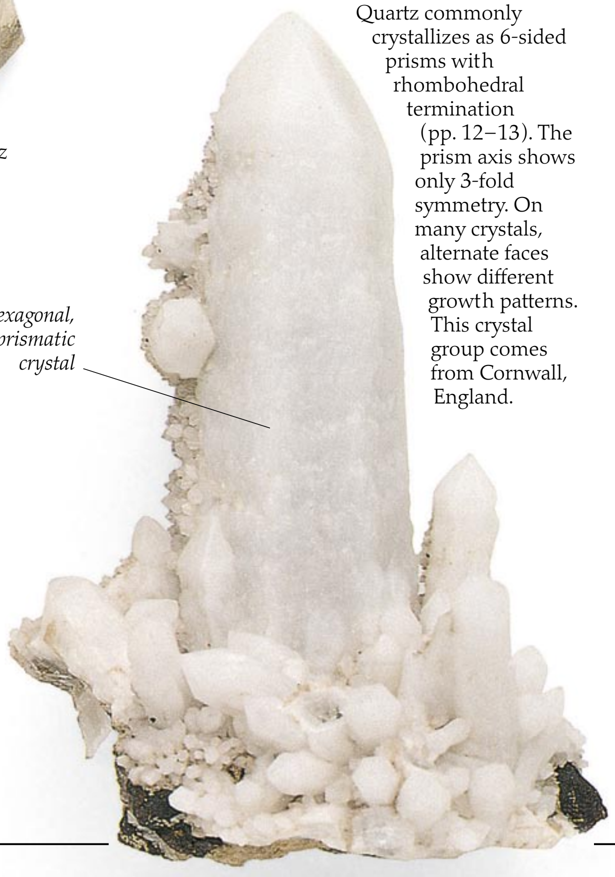
PAST FAVORITE
Quartz crystals from Brazil were important material for electronics before synthetic crystals were grown. Large quartz crystals are still found there, as demonstrated by this local miner, or *garimpeiro*.



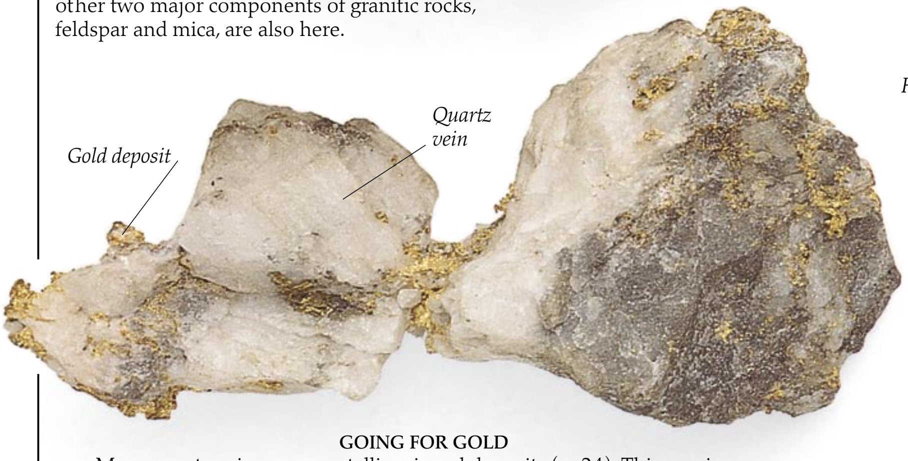
WAVES OF ENERGY
Quartz crystals are used in electronics. They can change a mechanical force, such as a blow from a hammer, into electrical energy, shown here as a wave-form on an oscilloscope screen.



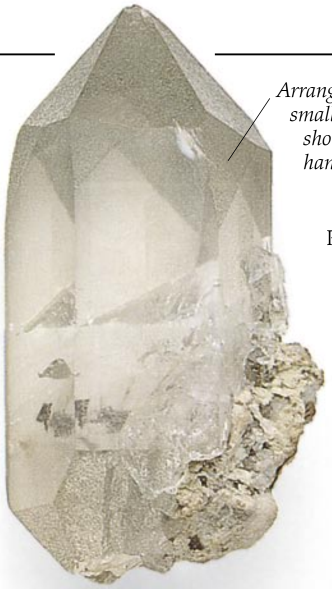
CRYSTAL TRIO
Large crystals of quartz can be seen in this granite pegmatite crystal group (p. 25). Fine crystals of the other two major components of granitic rocks, feldspar and mica, are also here.



ENGLISH PRISM
Quartz commonly crystallizes as 6-sided prisms with rhombohedral termination (pp. 12–13). The prism axis shows only 3-fold symmetry. On many crystals, alternate faces show different growth patterns. This crystal group comes from Cornwall, England.



GOING FOR GOLD
Many quartz veins carry metallic mineral deposits (p. 24). This specimen contains gold. It came from St. David's mine, Gwynedd, Wales, an area famous for the extraction of British gold. The quartz and gold were both deposited by hydrothermal (hot, watery) fluids. In mining practice, the quartz would be considered a "gangue," or unwanted mineral.



Arrangement of small faces shows left-handedness

Left-handed quartz crystal

Right-handed quartz crystal

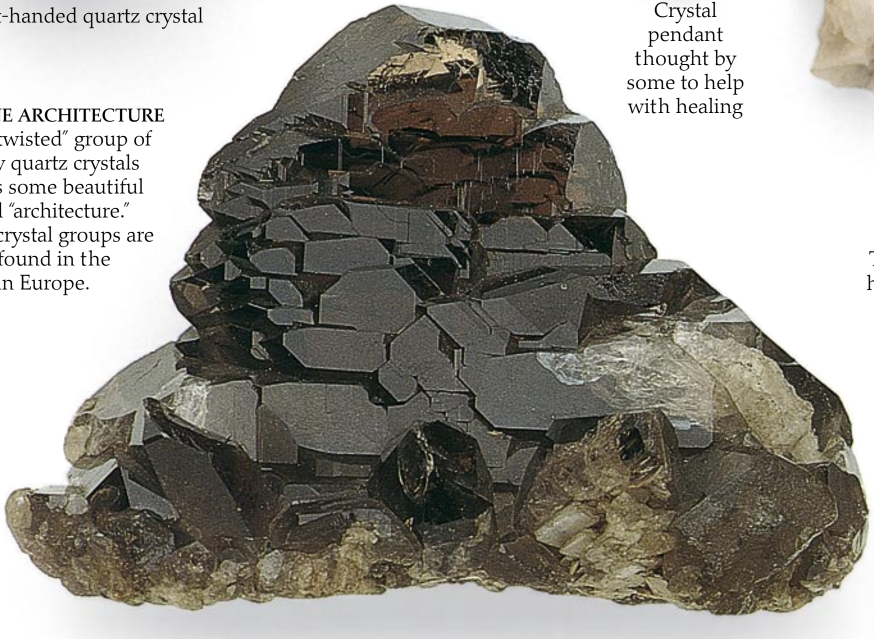
AMBIDEXTROUS
In a quartz crystal, silicon and oxygen atoms are joined in the shape of a tetrahedron (a four-sided triangular pyramid). These tetrahedra are connected in a spiral arrangement, like a spiral staircase, and can be left- or right-handed. It is this structure which accounts for the piezoelectricity of quartz.

Crystal pendant thought by some to help with healing

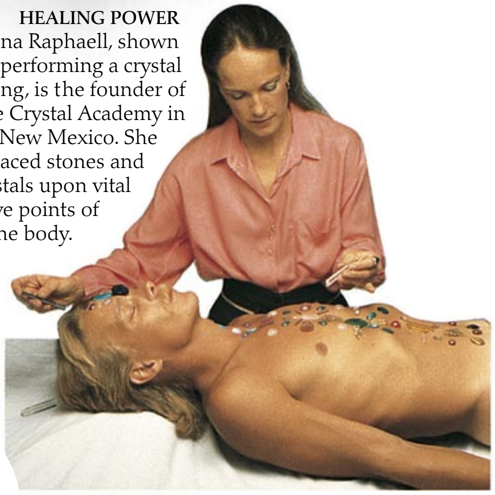
Crystal healing

The laying on of stones is an ancient art. It is thought that as light reflects off the crystals and stones, the electromagnetic field of the body – the aura – absorbs energy. The receiver can then become aware of mental and emotional causes of physical disease, and heal.

CRYSTAL CLEAR
Rock crystals from groups such as this one from Arkansas are highly prized for their beauty and clarity and are often used for crystal healing.



ALPINE ARCHITECTURE
This "twisted" group of smoky quartz crystals shows some beautiful crystal "architecture." Such crystal groups are often found in the Alps, in Europe.



HEALING POWER
Katrina Raphaell, shown here performing a crystal healing, is the founder of the Crystal Academy in Taos, New Mexico. She has placed stones and crystals upon vital nerve points of the body.

PURE NECESSITY
To meet the demand for pure, flawless quartz crystals necessary for making oscillator plates, synthetic crystals like this one are now grown by a hydrothermal process (p. 26).

Piezoelectricity

Piezoelectricity was discovered by the brothers Pierre and Jacques Curie in 1880. They discovered that pressure on a quartz crystal causes positive and negative charges to be produced across the crystal. It was later found that an alternating electrical charge placed on a piezoelectric crystal could cause the crystal to vibrate. This is the basis of the use of quartz as oscillator plates to control radio waves and keep time.

Jacques and Pierre Curie with their parents

Quartz crystal slice

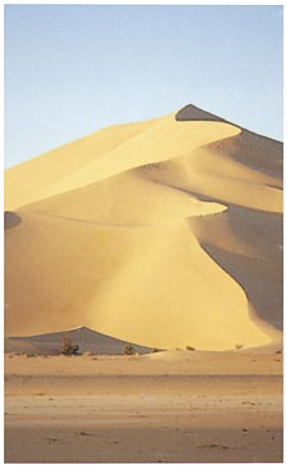
WATCH PIECE
This microthin quartz crystal slice is used to keep time in a quartz watch. The photograph is greatly enlarged.

SPLIT-SECOND TIMING
The crystal slice in a quartz watch vibrates more than 30,000 times each second. It is this regularity of vibration which makes it a good timekeeper.

Quartz

Quartz is silicon dioxide. It occurs as individual crystals and fine-grained masses in a large variety of forms, patterns, and colors. If conditions are right, giant crystals can grow (Brazil is famous for these). The largest recorded rock crystal was about 20 ft (6 m) long and weighed more than 48 tons (44,000 kg). Other sources of fine quartz include the Swiss Alps, the USA, and Madagascar. Quartz is tough and has no cleavage (p. 15), making it ideal for carving and cutting, and it is very popular as a gemstone. The name quartz usually refers to individual crystals or coarse-grained aggregates while the fine-grained materials are called chalcedonies or jaspers.

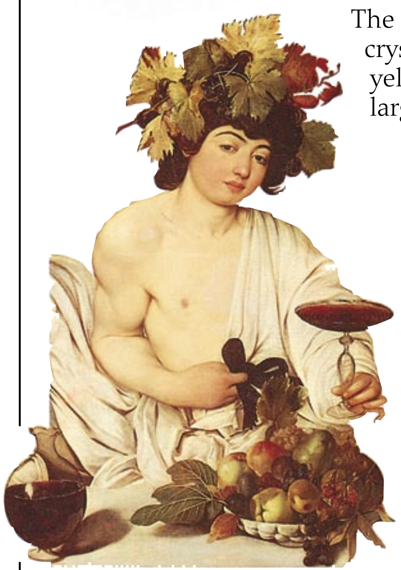
QUARTZ CRYSTAL
Crystal system: trigonal; hardness: 7; specific gravity: 2.65.



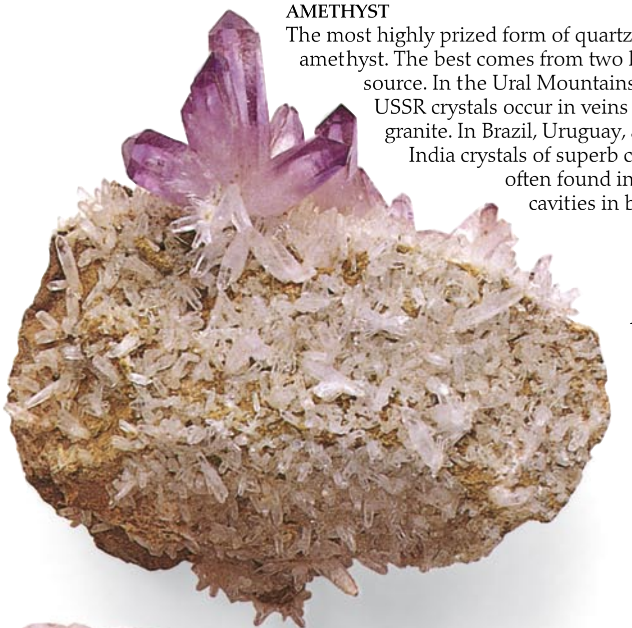
DUNES AND DUST
As quartz is relatively hard and common, it forms the major part of sand and also of dust in the air. Dust can therefore damage gems of 6 or less on Mohs' hardness scale (pp. 18–19).

Single crystals

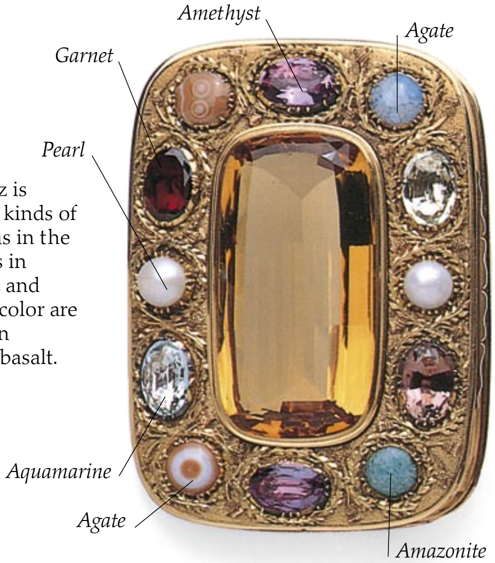
The best-known single crystals of quartz are colorless rock crystal, purple amethyst, rose quartz, smoky quartz, and yellow citrine. These transparent crystals often occur in large enough pieces to be cut as gemstones.



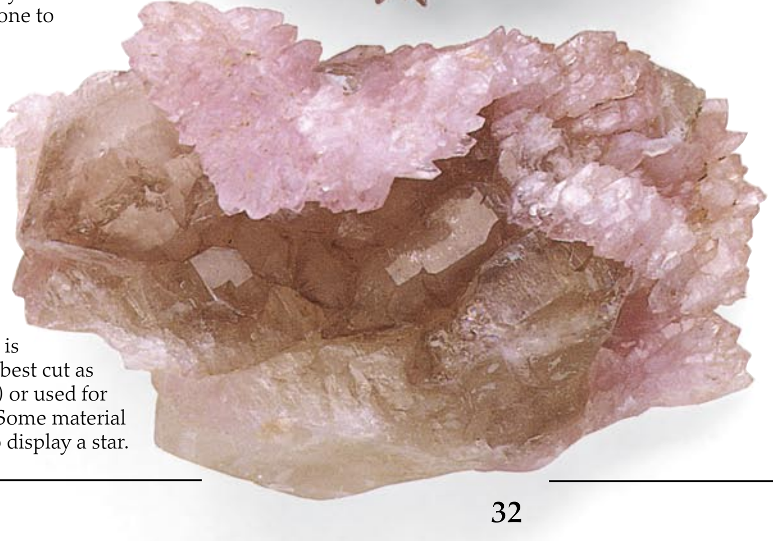
***BACCHUS* BY CARAVAGGIO**
A 16th-century French verse tells how Bacchus, the god of wine, declares in a rage that the first person he passes will be eaten by tigers. This turns out to be a beautiful maiden called Amethyst. The goddess Diana quickly turns Amethyst into a white stone to save her from the tigers. Regretting his anger, Bacchus pours red wine over the stone as an offering to Diana, so turning the stone purple.



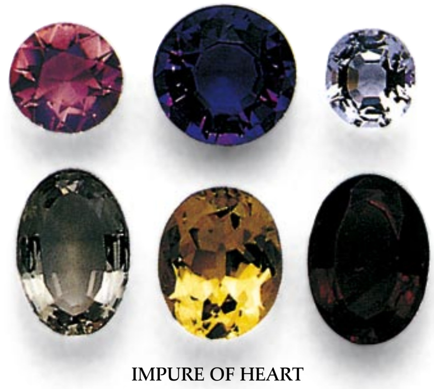
AMETHYST
The most highly prized form of quartz is amethyst. The best comes from two kinds of source. In the Ural Mountains in the USSR crystals occur in veins in granite. In Brazil, Uruguay, and India crystals of superb color are often found in cavities in basalt.



RARE BEAUTY
This 19th-century gold box is set with a superb rare citrine surrounded by a garnet (p. 44), an amazonite, two pearls (p. 55), two aquamarines (p. 39), three agates, and three amethysts.



ROSE QUARTZ
Single rose quartz crystals are very rare and most rose quartz is massive. It is best cut as cabochons (pp. 58-59) or used for carvings and beads. Some material can be polished to display a star.

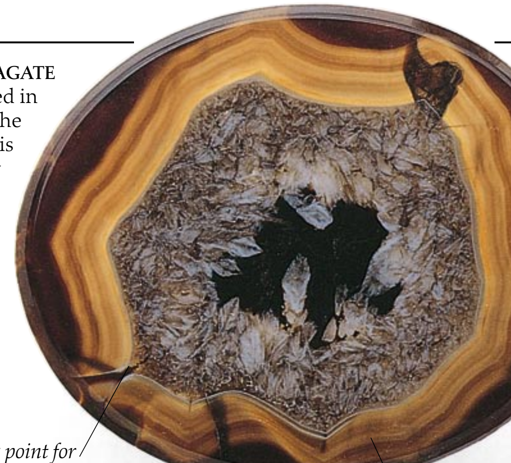


IMPURE OF HEART
Colorless rock crystal is the purest form of quartz, the many other colors being caused by impurities. Amethyst and citrine contain iron, rose quartz contains titanium and iron, and smoky quartz contains aluminum.

Massive

There are several massive varieties of quartz which are composed of very tiny grains or fibers. Chalcedony – such as carnelian, chrysoprase, and agate – and jasper are distinguished by the different arrangements of these grains. Tiger's-eye and hawk's-eye form when tiny fibers of asbestos are replaced by quartz and iron oxides.

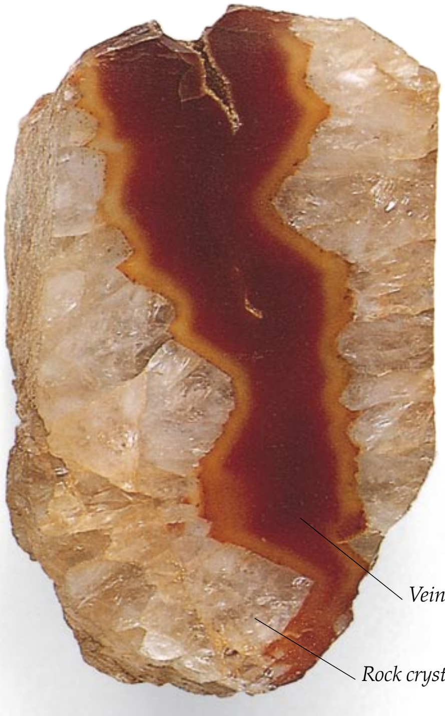
AGATE
The quartz grains in chalcedony are arranged in layers and their buildup is clearly visible in the different colored layers of agate. In this specimen they crystallized progressively toward the middle of a cavity in lava.



TIGER'S-EYE
Originally this vein of tiger's-eye contained silky blue crystals of asbestos. These were dissolved by solutions which deposited quartz and iron oxides in their place. The structure of the tiny fibers of asbestos was exactly reproduced by the quartz, and this gives rise to the light reflection or the "cat's-eye."

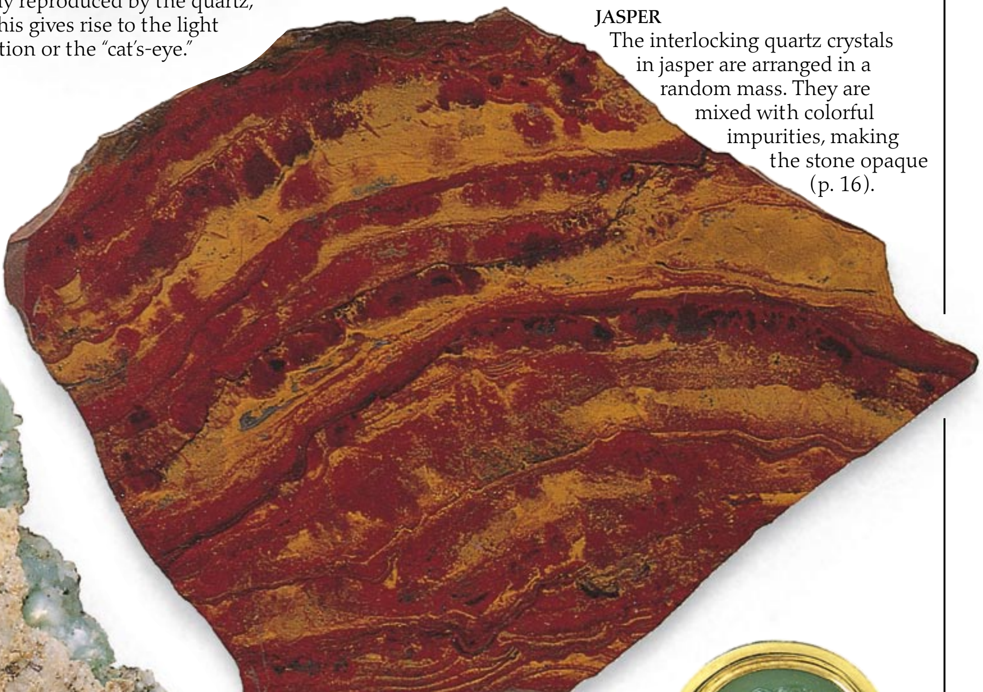
Polished tiger's-eye showing the cat's-eye effect called chatoyancy

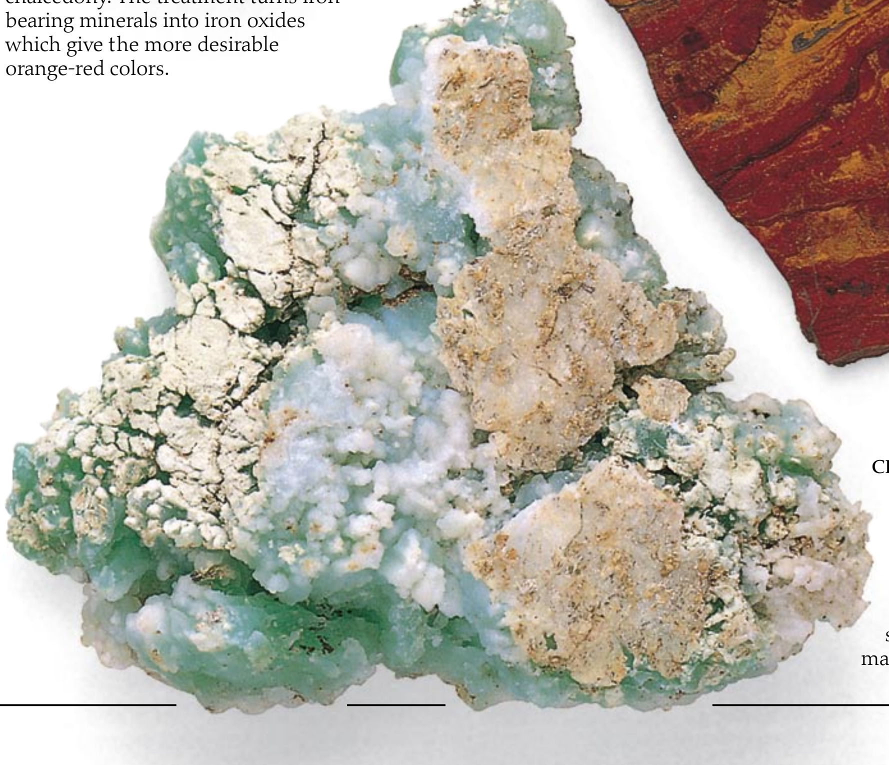
A tiger shows why tiger's-eye is so named



CARNELIAN
Carnelian is the name given to translucent (p. 16) orange-red chalcedony. Most specimens are the result of heat-treating a less attractive chalcedony. The treatment turns iron-bearing minerals into iron oxides which give the more desirable orange-red colors.

JASPER
The interlocking quartz crystals in jasper are arranged in a random mass. They are mixed with colorful impurities, making the stone opaque (p. 16).





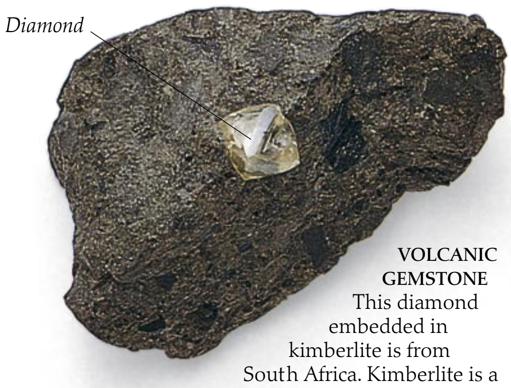
CHRYSOPRASE
At its finest, chrysoprase is a vibrant green and the most valuable of the chalcedonies. It has been used in ornament and decorative patterns since prehistoric times. A recent source of some of the best material is Queensland, Australia.

Chrysoprase cameo set in gold

Diamond

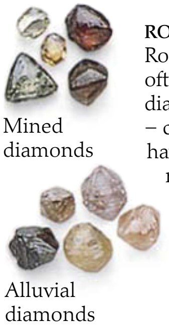
DIAMOND CRYSTAL
Crystal system: cubic; hardness: 10; specific gravity: 3.5.

THE WORD DIAMOND is derived from the Greek word *adamas*, meaning "unconquerable," given to the stone because of its supreme hardness. Diamond is made of pure carbon and has an immensely strong crystal structure (p. 14). It is this which makes it the hardest of all minerals. Evidence suggests that diamonds were formed up to 125 miles (200 km) deep within the earth, and some stones may be as much as three billion years old. Diamonds were first discovered over 2,000 years ago and came mainly from river gravel in India. In 1725, they were found in Brazil, which remained the major source until production in South Africa became significant in 1870. Today, about 20 countries produce diamonds. The top producer is Australia, which supplies a quarter of the world's needs, mainly for industrial purposes (p. 29). Diamond has great luster and fire, properties which are best revealed in the brilliant cut (p. 58).

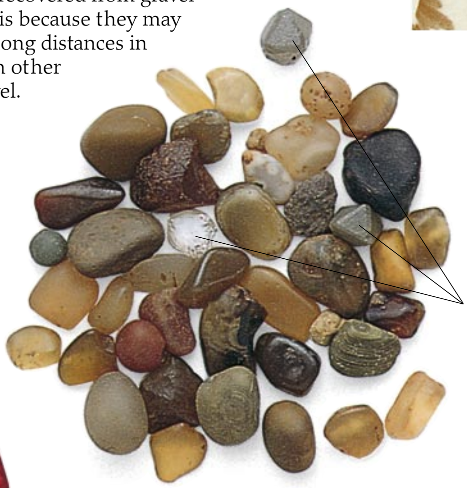


VOLCANIC GEMSTONE
This diamond embedded in kimberlite is from South Africa. Kimberlite is a volcanic rock that was first discovered in the Kimberley region of South Africa.

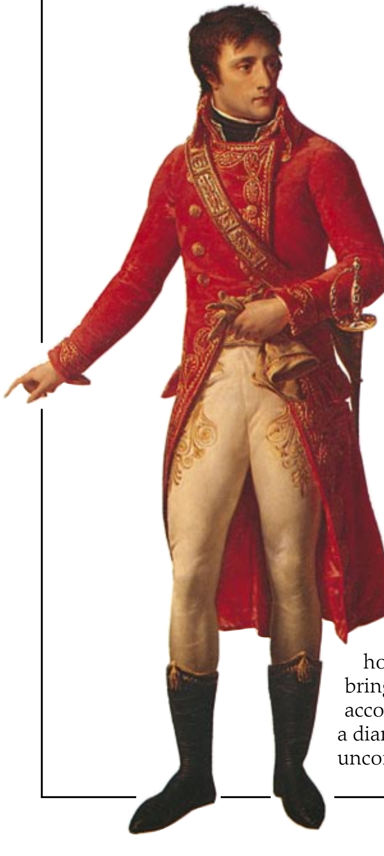
DIAMOND RUSH
In 1925 some very rich alluvial deposits were discovered at Lichtenburg, South Africa. The government decided to allocate claims (areas of land to mine) on the outcome of a race. So, on August 20, 1926, 10,000 miners lined up and had to race about 218 yards (200 m) to stake their claims.



ROUGH DIAMONDS
Rough diamonds mined from kimberlites often have lustrous crystal faces; alluvial diamonds – those recovered from gravel – can be dull. This is because they may have been carried long distances in rough water with other rocks and gravel.



SPOT THE DIAMONDS
Diamond-bearing gravel is the result of one of nature's sorting processes. Seriously flawed or fractured stones are more likely to be broken up and eroded away, so a high proportion of the diamonds found in gravel are of gem quality.

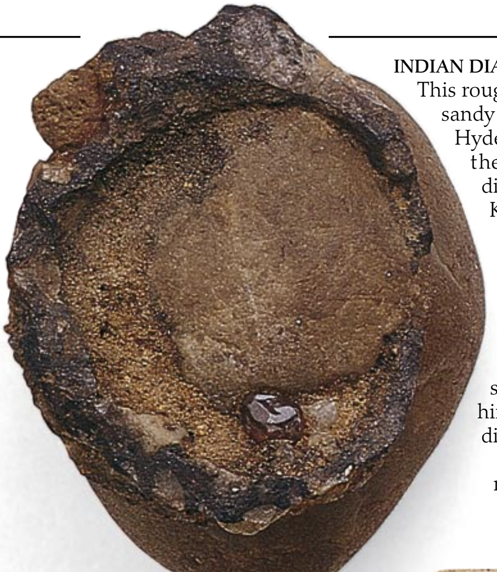


UNCONQUERABLE BELIEF
Napoleon Bonaparte is depicted here as First Consul wearing a sword set with the Regent diamond. He hoped the diamond would bring him victory in battle; according to an ancient belief, a diamond made its wearer unconquerable.

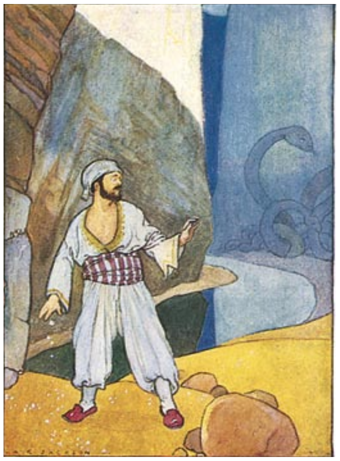
RICH MIX
Conglomerate rock is a mixture of different sizes of rounded pebbles and mineral grains which have been deposited from water and cemented together. This specimen from the west coast of South Africa is particularly rich in diamonds.

Famous diamonds

Diamonds of exceptional beauty and rarity are highly prized. Some have long, recorded histories and others have inspired fantastic legends. Most belong to the rich and famous.

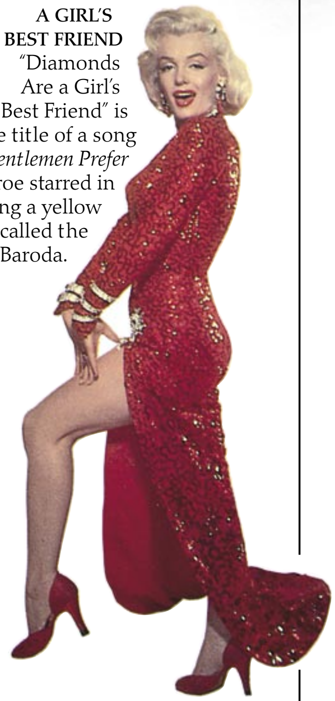


INDIAN DIAMOND
This rough diamond is embedded in a sandy conglomerate found near Hyderabad in India. This area was the source of many famous large diamonds such as the Koh-i-noor and the Regent.

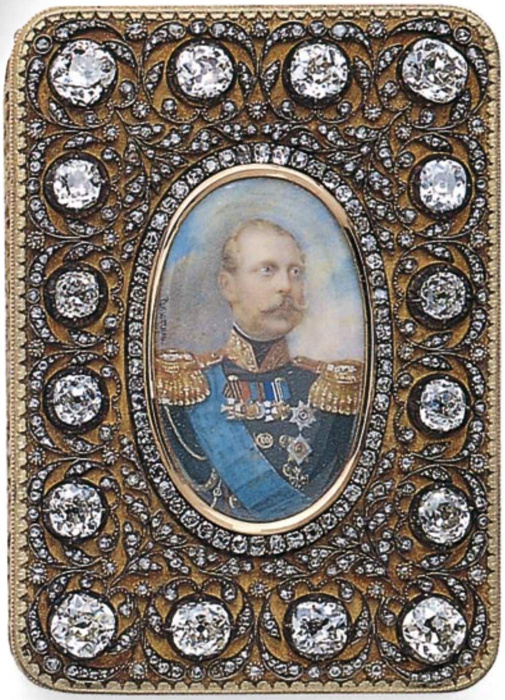


VALLEY OF DIAMONDS
Sindbad was once stranded in the legendary Valley of Diamonds. On the valley floor were diamonds guarded by snakes. Sindbad escaped by tying himself to meat thrown down by a diamond collector. As intended by the collector, a bird carried the meat out of the valley stuck with diamonds – and Sindbad!

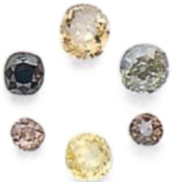
BUTTERFLY BROOCH
This butterfly brooch is set with over 150 diamonds.



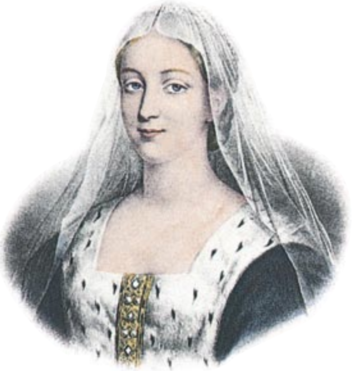
A GIRL'S BEST FRIEND
"Diamonds Are a Girl's Best Friend" is the title of a song from the film *Gentlemen Prefer Blondes*. Marilyn Monroe starred in the film wearing a yellow diamond called the Moon of Baroda.



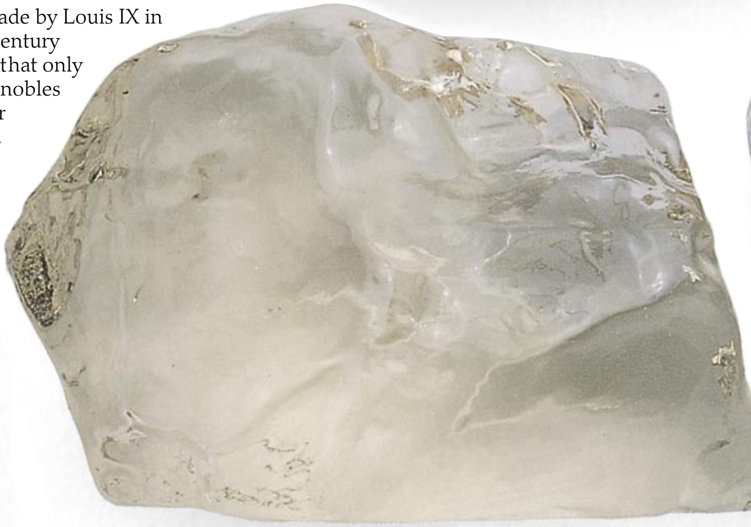
MURCHISON SNUFFBOX
This gold box set with diamonds bears a portrait of Czar Alexander II of Russia. It was presented in 1867 by the czar to Sir Roderick Murchison, the second director of the British Geological Survey, in recognition of Sir Roderick's geological work in Russia.



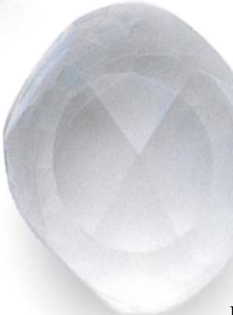
BRILLIANT COLORS
Most natural diamonds are near-colorless; truly colorless ones are rare. A few stones are also found of all colors in the spectrum (p. 16) and good-quality ones are known as fancies.



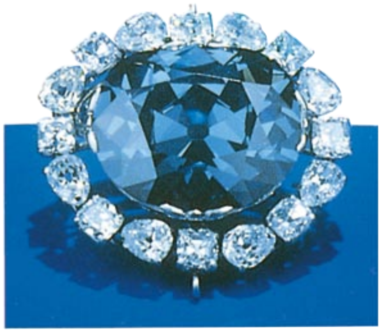
AGNÈS SOREL (c 1422-1450)
Agnès Sorel, the mistress of the French king Charles VII, was the first commoner in France to break the law made by Louis IX in the 13th century decreeing that only kings and nobles could wear diamonds.



PREMIER DIAMOND
In 1905 the Cullinan crystal was found in the Premier diamond mine in the Transvaal, South Africa. It weighed 3,106 carats and is still the largest diamond ever found. This replica shows its actual size. In 1908 it was cut into 9 large and 96 lesser stones. The two largest, Cullinan I and II, are in the British crown jewels (p. 46).



THE JEWEL IN THE CROWN
The Koh-i-noor (mountain of light) is claimed to be the oldest large diamond. It was probably found in India and after belonging to Mogul kings was presented to Queen Victoria in 1850. Its cut, shown in this replica, was unimpressive, so it was recut (p. 58). Today, it is in the British crown jewels.

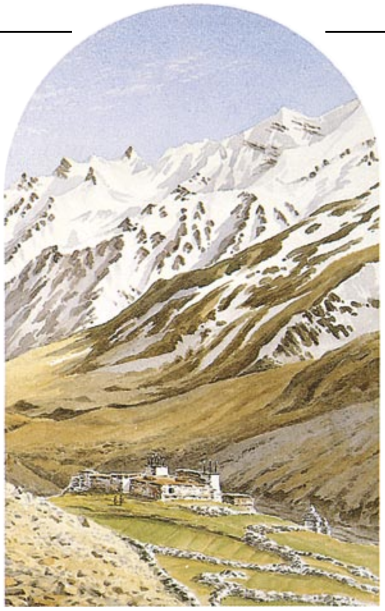


BLUE HOPE
The Hope has a reputation for bringing bad luck, but the sinister stories are untrue. It is 45.52 carats and is now in the Smithsonian Institution, Washington D.C.

Corundum

Ruby and sapphire are varieties of the mineral corundum, an aluminum oxide. Only true red stones are called rubies, and the term *sapphire* on its own indicates a blue stone. Other colors are described as sapphire, that is, yellow sapphire and pink sapphire. Corundum is next to diamond in hardness, so gem crystals are resistant to wear. It is pleochroic, which means the color of a stone varies when it is viewed in different directions. Most gem crystals are recovered from gravel, and the most famous sources are Myanmar (formerly Burma), Kashmir, and Sri Lanka. Today, Australia is the largest producer of blue and golden sapphires. Other producers include Thailand and countries in East Africa.

CORUNDUM
Crystal system: trigonal; hardness: 9; specific gravity: 3.96–4.05.



SOURCE REVEALED
A famous source of fine sapphires is in a valley in the Kanskar range of the Himalayas in Kashmir. It is said the source was only revealed after a landslide in about 1881.

Twin sapphire crystals

Sapphire intergrown with tourmaline

KASHMIR BLUE
Kashmir has a reputation for producing sapphires of the finest blue, like these two examples. The term *Kashmir blue* is often used to describe sapphires of this color from other parts of the world.

RUSKIN'S RUBY
This Myanmar ruby crystal was presented to the Natural History Museum in London by the philosopher John Ruskin in December 1887. It is about 162 carats. Its deep red color is the most admired color for a ruby and is sometimes described as "pigeon's blood" red.

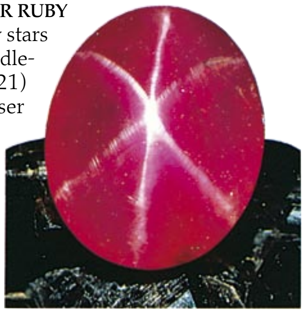
MYANMAR CRYSTAL
Most of the highest-quality rubies come from the Mogok region in Myanmar, and this fine crystal embedded in calcite is a good example. Rubies from Myanmar, Pakistan, and Afghanistan are often found in calcite.

Flattened prism of fine-quality ruby from the Mogok district of upper Myanmar

BAZAAR DEALING
This 1930 photograph shows ruby dealers in a Mogok bazaar. Gem-quality corundum is rare, and ruby is the most valuable variety of all. Good quality stones can fetch even higher prices than diamonds of the same size.

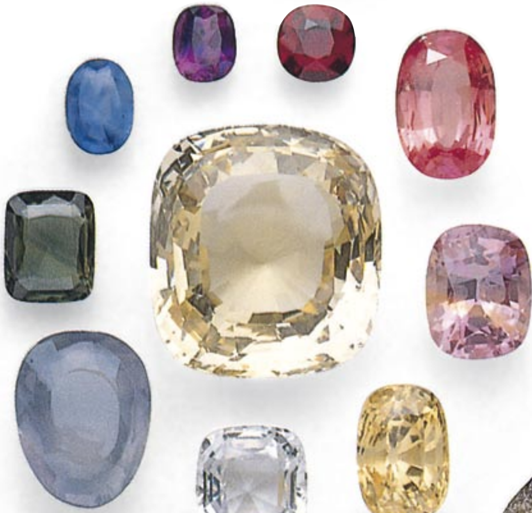
IN A SPINEL
Sapphires are often found with spinels (p. 46) in gem gravel but they are rarely found in their source rock. This sapphire from Myanmar has grown with crystals of spinel. The crystals grew in conditions of high temperature and pressure.

QUEEN CAMEO
These gems were mounted on a rock crystal pitcher in about 1660. The pitcher was rediscovered in 1985. In the center is a ruby cameo of the head of Queen Elizabeth I of England.

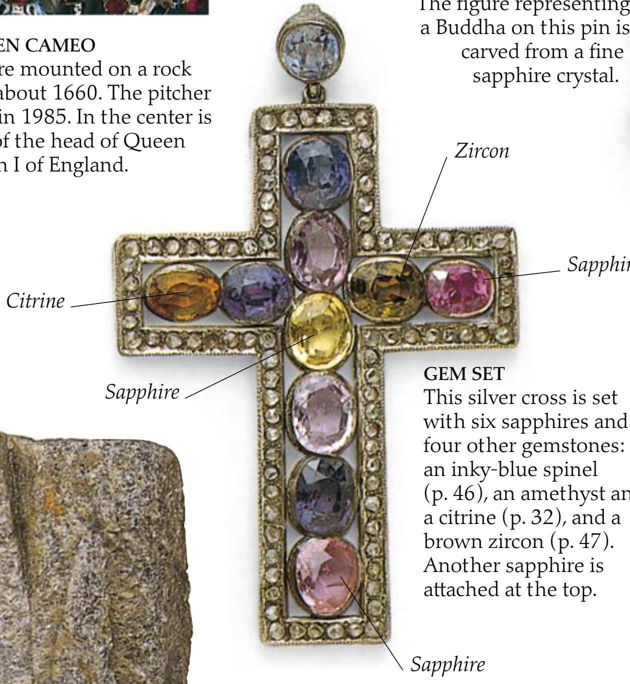


STAR RUBY
Some rubies display stars caused by fine needle-like inclusions (p. 21) of rutile. The Rosser Reeves ruby is one of the finest. It weighs 138.7 carats and belongs to the Smithsonian Institution, in Washington D.C.

BLUE BUDDHA
The figure representing a Buddha on this pin is carved from a fine sapphire crystal.

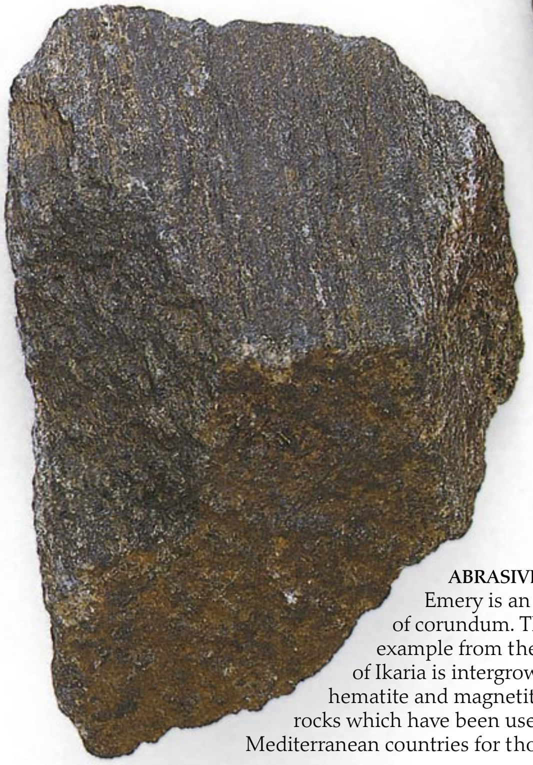


RICH COLORS
Pure corundum is colorless, but tiny amounts of impurities are responsible for a wide range of rich colors: chromium (red), iron (yellow and green), and iron and titanium (blue).

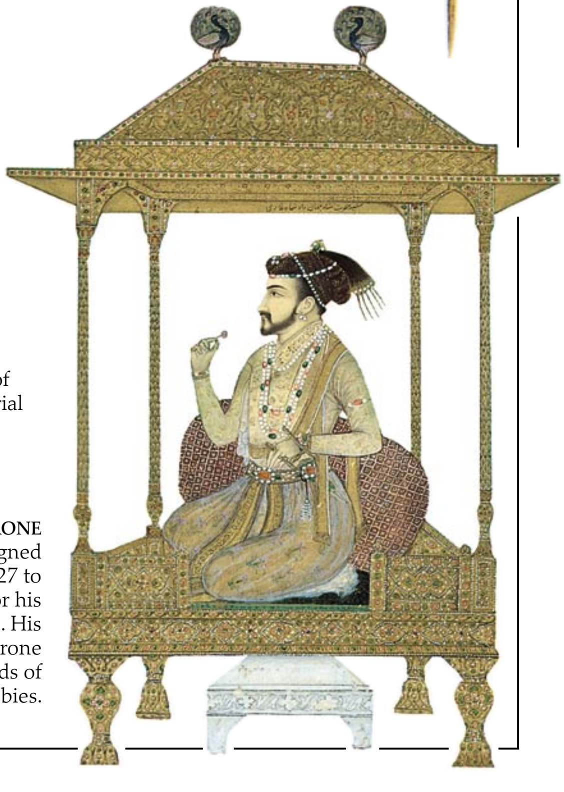


GEM SET
This silver cross is set with six sapphires and four other gemstones: an inky-blue spinel (p. 46), an amethyst and a citrine (p. 32), and a brown zircon (p. 47). Another sapphire is attached at the top.

HARD AS ROCK
Most natural corundum is not of gem quality. It is opaque and gray or brown like this crystal from Madagascar. Because of its hardness this material is used on industrial tools, and in the past it was used for fashioning other softer stones.



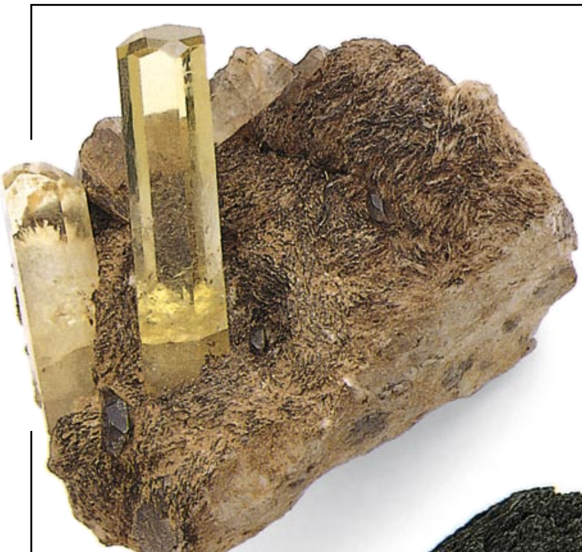
ABRASIVE ROCK
Emery is an impure type of corundum. This fine-grained example from the Greek island of Ikaria is intergrown with black hematite and magnetite. It is typical of rocks which have been used as abrasives in Mediterranean countries for thousands of years.



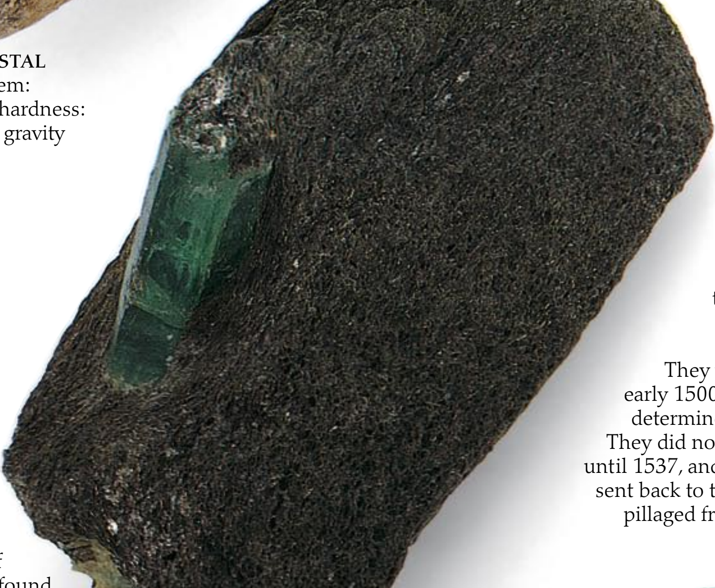
PEACOCK THRONE
Shah Jahan, who reigned over Persia from 1627 to 1658, was famous for his knowledge of gems. His legendary Peacock Throne was set with hundreds of gems including 108 rubies.

Beryl

Beryls are popular as gems because of their fine colors and resistance to wear. The most well-known varieties are emerald (green) and aquamarine (blue-green). Yellow beryl is known as heliodor, and pink beryl is morganite. The name beryl can be traced to Greek, Roman, and possibly Sanskrit sources, and it is highly likely that aquamarine and heliodor were known in prehistoric times. Beryl is found in pegmatites (p. 25) and granites and in its massive, opaque, non–gem form can occur in crystals weighing many tons. The recordholder is a crystal which was found in Madagascar weighing 36 tons and measuring about 60 ft (18 m) long.

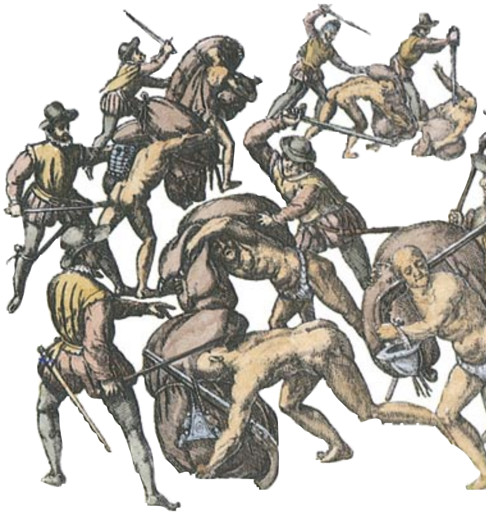


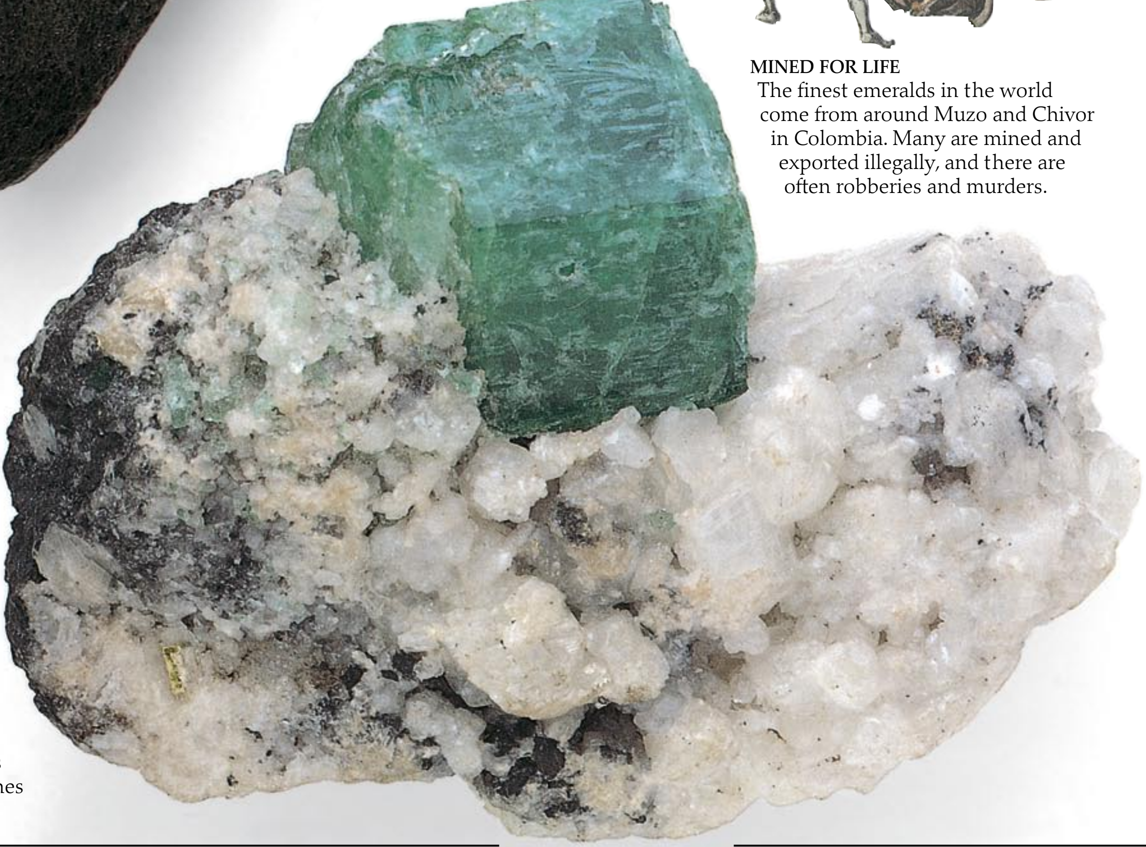
BERYL CRYSTAL
Crystal system: hexagonal; hardness: 7.5; specific gravity 2.63–2.91.



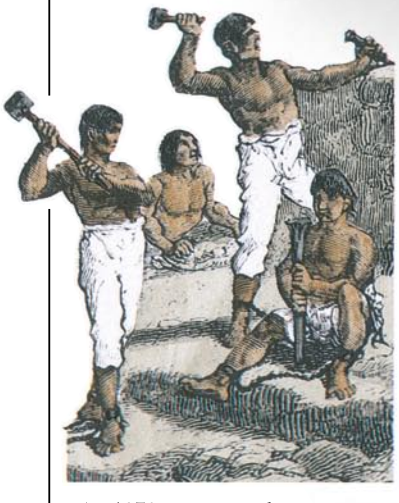
SOVIET HOST
A typical source of emeralds is mica schist. This kind of source was found in the early 1800s in the Ural Mountains, USSR. Many of these crystals have mica and amphibole inclusions (p. 21), the same rock as the host.

SPANISH SPOILS
The Chibcha Indians of Colombia mined emeralds which, through trade, reached the Incas of Peru and the Aztecs of Mexico. They were seen there in the early 1500s by the Spanish, who determined to find their source. They did not find the Chivor mine until 1537, and most of the emeralds sent back to the Spanish court were pillaged from the Incas' treasure.



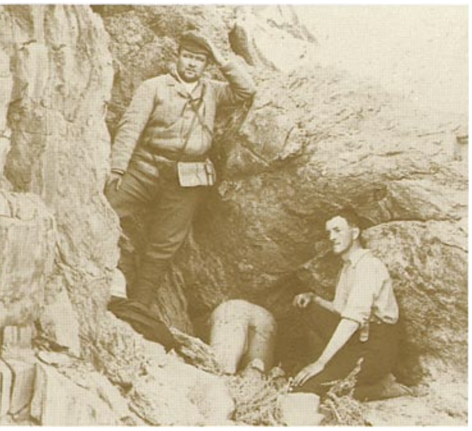


MINED FOR LIFE
The finest emeralds in the world come from around Muzo and Chivor in Colombia. Many are mined and exported illegally, and there are often robberies and murders.



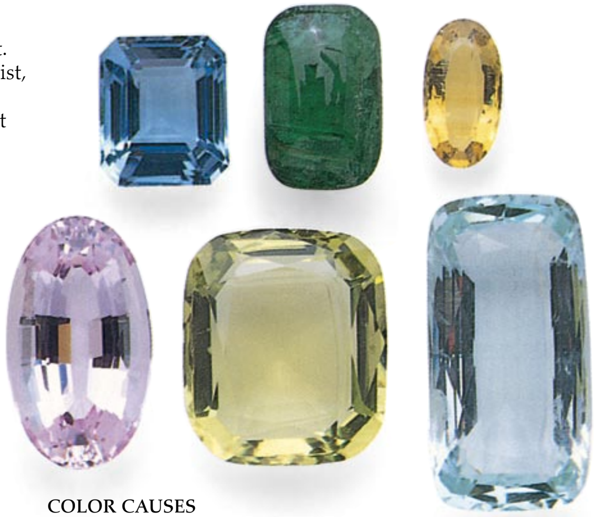
An 1870 engraving showing convicts working the Colombian emerald mines

SECOND-CLASS CRYSTAL
A few emeralds are still found in Egypt. They come from an area of granite, schist, and serpentine. Most crystals are blue-green with many inclusions and do not compare in quality with the best Colombian emeralds.



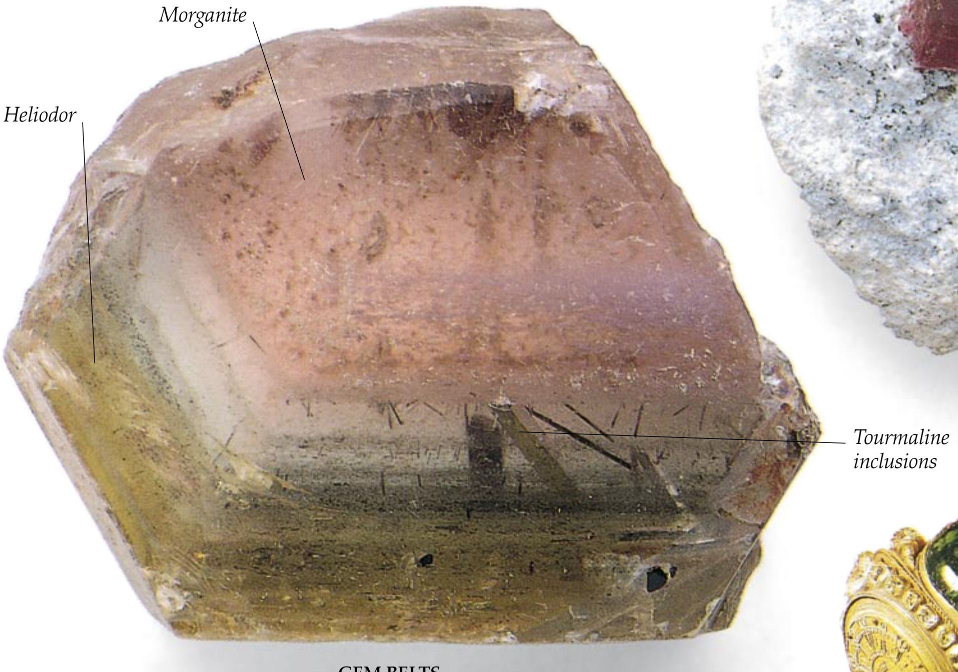
ANCIENT ACCESS
Emeralds were mined near the Red Sea in Egypt from about 1500 B.C. The mines were rediscovered in 1816 by the French adventurer Cailliaud, but attempts at mining were not a success. This old entrance to one of Cleopatra's mines was discovered in about 1900.

FINE CUT
This exceptionally fine, 911-carat, cut aquamarine belongs to the Smithsonian Institution in Washington, D.C.



COLOR CAUSES
Pure beryl is colorless. The spectacular reds and pinks are caused by manganese, the blues and yellows by iron. The beautiful emerald green is due to tiny amounts of chromium or vanadium.

SEA-GREEN
Aquamarine means "sea water," which accurately describes its color. It has a range from pale green to blue, caused by varying amounts of different forms of iron. It is relatively common, with sources in many countries; the main source is Brazil.



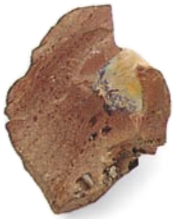
GEM BELTS
This large crystal of beryl is made up of zones of the varieties morganite and heliodor. This gem-quality specimen comes from Brazil, but other sources of these varieties include California, Madagascar, and Pakistan.

DRY RED
Red beryl is extremely rare and is the only natural beryl that contains no water in its crystal structure. It occurs in "dry" volcanic rocks in the western USA. This fine specimen comes from the Wah Wah Mountains in Utah.

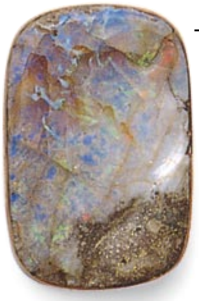
TURKISH DELIGHT
The Topkapi Palace Treasury in Istanbul, Turkey, contains many pieces with fine emeralds. The hilt of this 18th-century dagger holds three, plus one cut as a hexagonal slice and hinged over a small watch at the end.

Opal

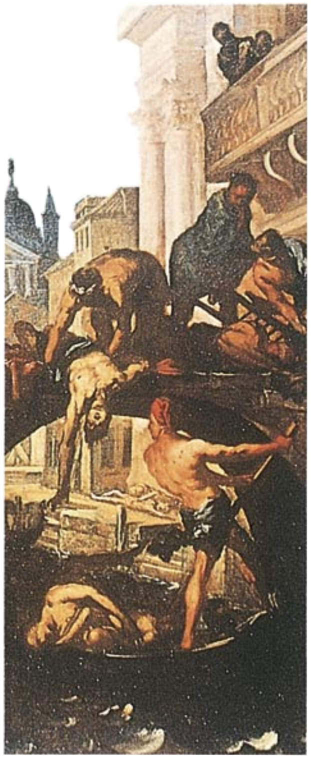
THE POPULARITY OF OPAL has risen and fallen over the centuries. The ancient Romans used it as a symbol of power but since then, at different times, it has been considered to be unlucky. The Aztecs mined opal over 500 years ago in Central America; this area is still an important source, especially of fire opal, from Mexico. Australia is the top producer of both black and white opals; they were first discovered there in the 1870s. Opal is one of the few noncrystalline gems. It has a tendency to crack and chip, especially under extreme temperature changes or after a hard knock. The exciting flashes of color shown by precious opal are best displayed in cabochons, but Mexican fire opals are usually cut as brilliants or step cuts (p. 58).



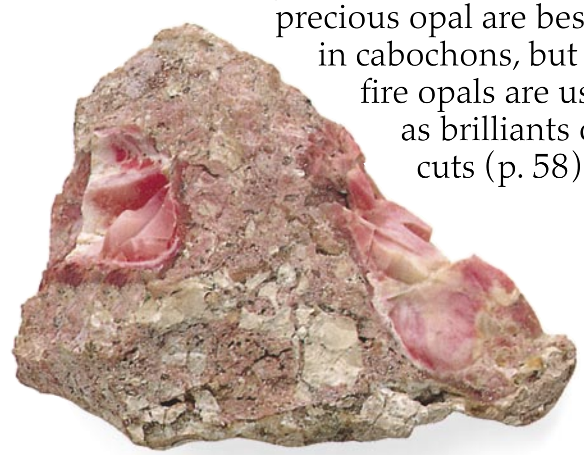
OPAL
Crystal system: amorphous or poorly crystalline; hardness: 5.5–6.5; specific gravity: 1.98–2.25.



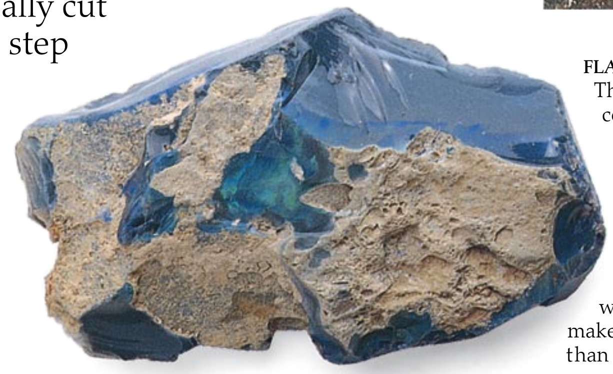
ROMAN SOURCE
This piece of white opal comes from Cervenica, Czechoslovakia, the source used by the Romans. This region was once part of Hungary, and the opal from here is usually described as Hungarian.



THE PLAGUE OF VENICE
This detail of a painting by Antonio Zanchi depicts the Black Death of the 14th century. The people in Venice, Italy, noticed that opals became brilliant when a wearer caught the disease and dulled when the person died. This reinforced the belief that opals were unlucky.

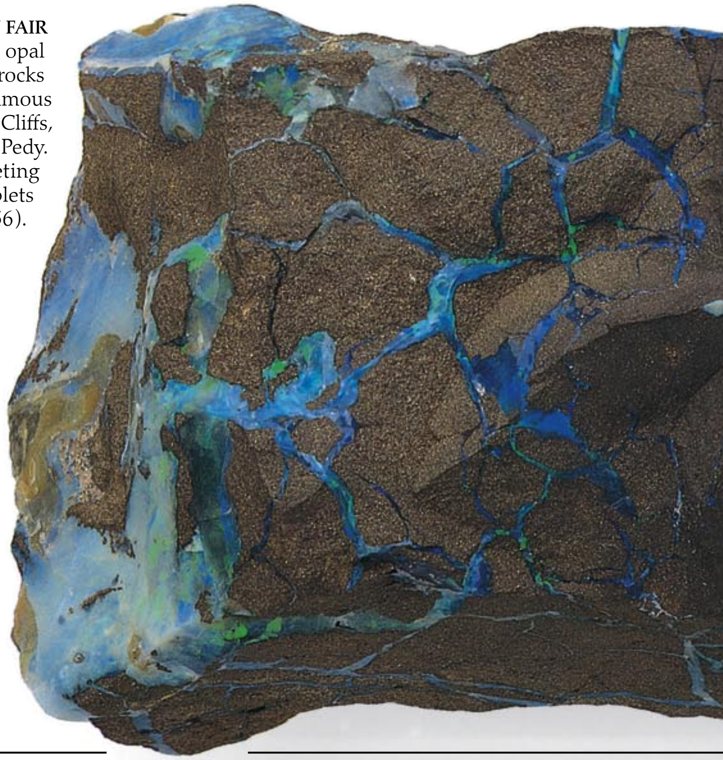


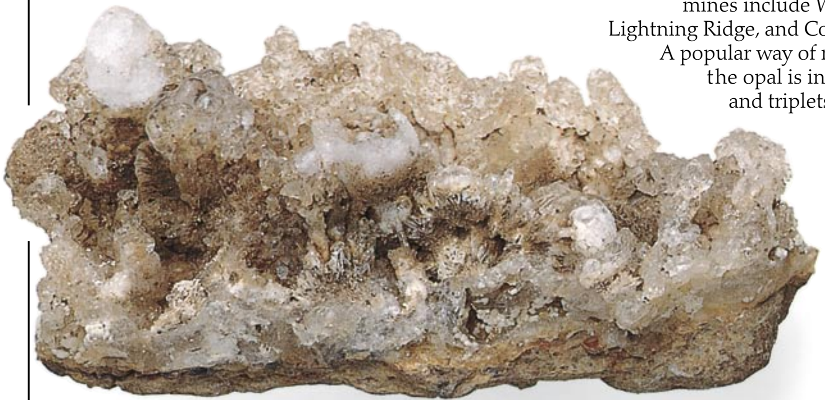
NONFLASHY
Nonprecious opal without flashes of color is called potch opal. Rose opal is potch, but its striking color has led to its being used in beads and decorative jewelry. This specimen comes from France; there are other sources in Idaho.



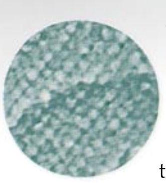
FLASH OF LIGHTNING
The finest black opal comes from Lightning Ridge, New South Wales, Australia. Against its dark body the color flashes are quite dramatic and this attraction, coupled with its greater rarity, make it more valuable than white opal.

AUSTRALIAN FAIR
All the major Australian opal deposits occur in sedimentary rocks in the Great Artesian Basin. Famous mines include White Cliffs, Lightning Ridge, and Coober Pedy. A popular way of marketing the opal is in doublets and triplets (p. 56).

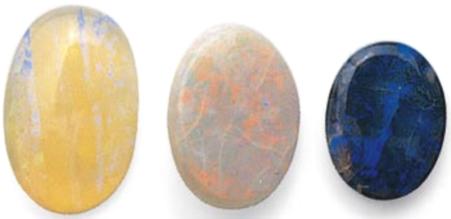




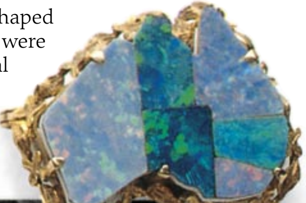
GLASSY LOOK
Clear, glassy-looking opal (hyalite) occurs in cavities in volcanic lavas. This example is from Bohemia (Czechoslovakia) but there are several other sources. If similar material shows a play of color, it is known as water opal. Another kind of opal, called hydrophane, is opaque but appears colorless in water.



Greatly enlarged photograph of precious opal, showing the ordered silica spheres in the structure that cause the play of colors

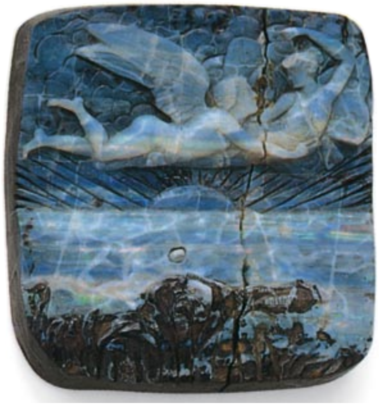


FLASHING LIGHTS
Precious opal displays flashes of different colors. The colors depend on the size of the silica spheres in the structure. Opal with a background color of gray, blue, or black is called black. Others are called white.

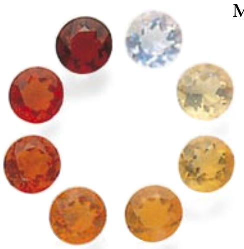


ON THE MAP
"Prospector's brooches," shaped like the map of Australia, were made to mark the arrival on the gemstone market of Australian opal. This one is thought to have been made around 1875.

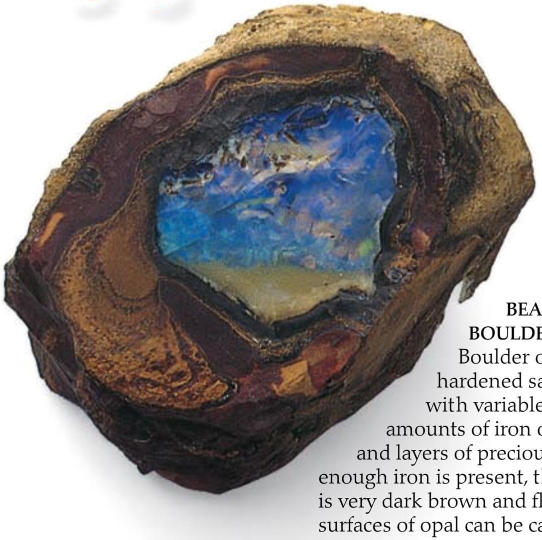
MOVED IN
The opal localities in Australia are extremely hot, so when mines are exhausted, those excavations near the surface are adapted to provide relatively cool and pleasant living conditions.



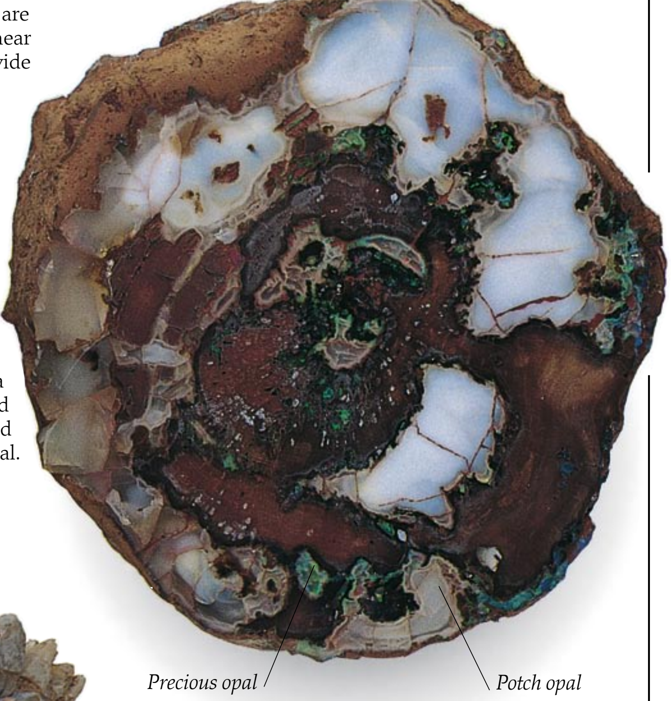
Opal cameo *Dawn with Cupid and Psyche* now in the Natural History Museum, London



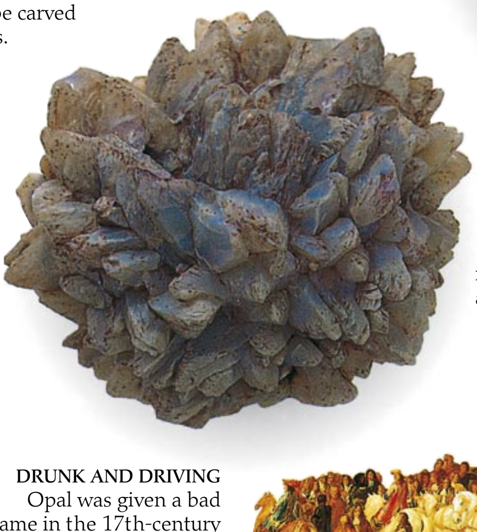
MEXICAN FIRE
Mexico has long been famous for its fire opal. This is a nearly transparent variety, still showing flashes of color. It ranges from yellow to orange and red.



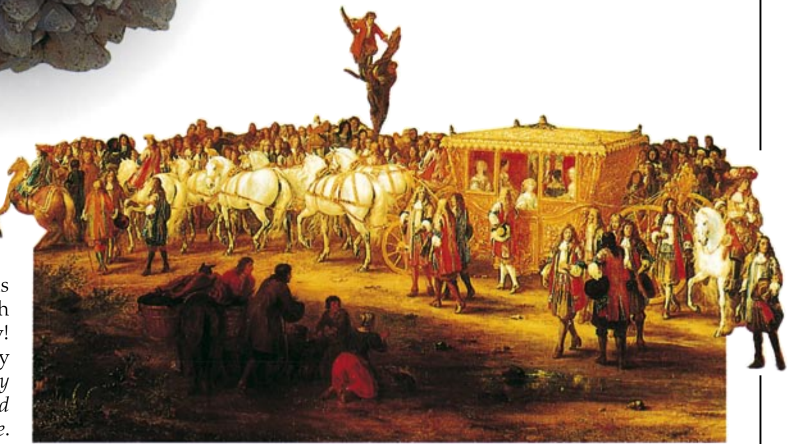
BEAUTIFUL BOULDER
Boulder opal is hardened sandy clay with variable amounts of iron oxides and layers of precious opal. If enough iron is present, the rock is very dark brown and flat surfaces of opal can be carved into beautiful cameos.



PRECIOUS FOSSIL
Opal often replaces the tissues of wood, and bones and shells of ancient animals, in a kind of fossilization. It grows bit by bit in place of the original material. This piece of wood from Nevada has been replaced by precious and potch opal.



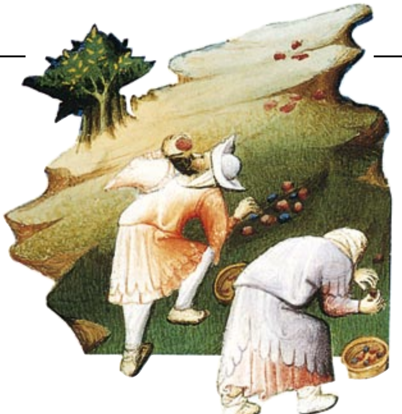
OPAL FRUIT
This was an aggregate (p. 22) of radiating crystals of glauberite. It has been completely replaced by precious opal. This kind of opal is found in Australia and is popularly known as pineapple opal.



DRUNK AND DRIVING
Opal was given a bad name in the 17th-century court of the French king Louis XIV. He named his coaches after gemstones. The driver of the *Opal* was usually drunk, and the coach was considered unlucky! This is a detail of a picture by Van der Meulen called *Entry into Arras by Louis XIV and Marie Thérèse*.

Other gemstones

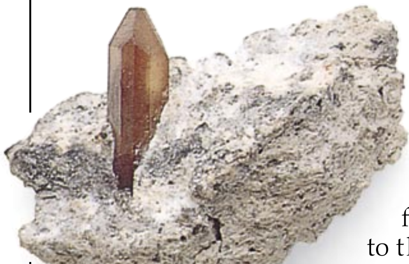
THE PROPERTIES OF A GEMSTONE are said to be beauty, rarity, and durability, and these standards have been applied to many species. As well as quartz (pp. 32–33), diamond (pp. 34–35), ruby and sapphire (pp. 36–37), beryl (pp. 38–39), and opal (pp. 40–41), gemstones to be seen in jewelers' shops include topaz, tourmaline, garnet, peridot, and many others. Some species, such as kunzite, sphene, and fluorite, are top soft or rare to be in general circulation as gemstones and are cut only for collectors on the basis of their beauty and rarity.



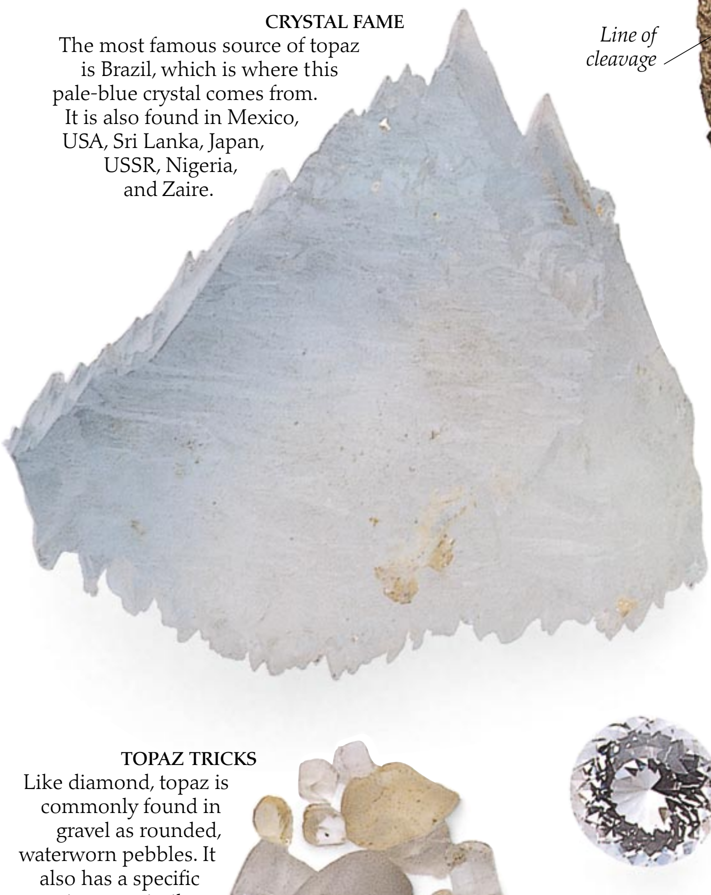
MARVELOUS GEMS
"Fishing for pearls and gathering turquoises" from *The Book of Marvels* by Marco Polo.

Topaz

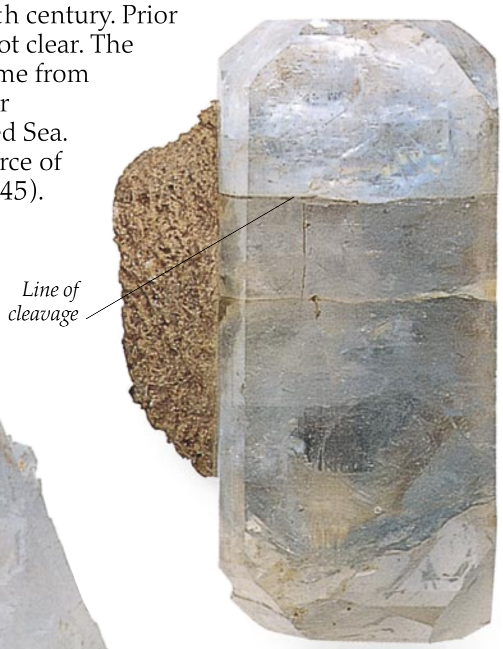
The mineral we know as topaz was only given the name in the first half of the 18th century. Prior to that its history is not clear. The name topaz is said to come from *Topazius*, the Greek name for Zabargad, an island in the Red Sea. This island is, however, a source of what we now call peridot (p. 45).



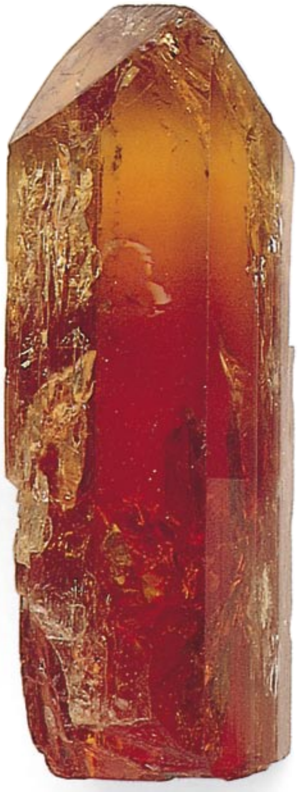
TOPAZ CRYSTAL
Crystal system: orthorhombic; hardness: 8; specific gravity: 3.52–3.56.



CRYSTAL FAME
The most famous source of topaz is Brazil, which is where this pale-blue crystal comes from. It is also found in Mexico, USA, Sri Lanka, Japan, USSR, Nigeria, and Zaire.

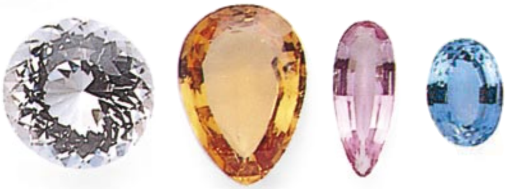


NEEDS PROTECTION
Although it is very hard, topaz can be broken easily because it has one direction of perfect cleavage (p. 15). A line of cleavage can be seen clearly in this crystal. If the topaz is used in jewelry, the setting must therefore provide protection from accidental knocks.



ONE OF THE BEST
The finest golden topaz crystals come from the Ouro Preto area in Brazil, and this wedge-shaped prism is typical of them. Some may show color zoning from golden brown to pink. Gems containing a hint of pink are often called imperial topaz.

TOPAZ TRICKS
Like diamond, topaz is commonly found in gravel as rounded, waterworn pebbles. It also has a specific gravity very similar to that of diamond and this has led to some premature celebrations.

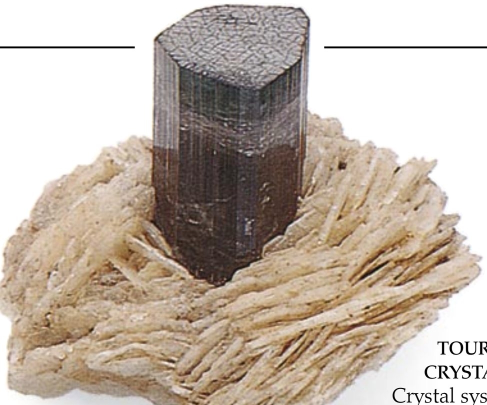


WATER COLORS
Topaz is an aluminum silicate containing about 20 percent water and fluorine. Those crystals with more water than fluorine are golden brown or, rarely, pink; those with more fluorine than water are blue or colorless.

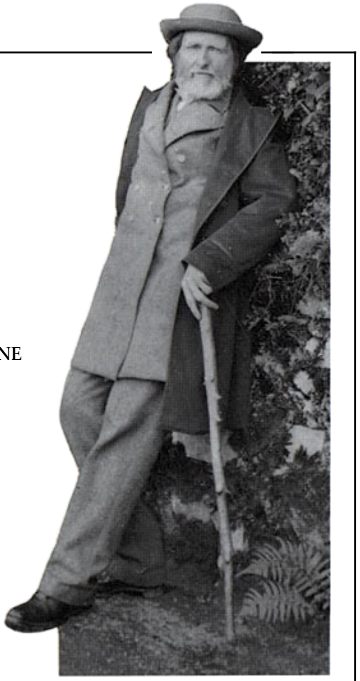
BRAZILIAN PRINCESS
This topaz was cut in 1977 and weighed 21,327 carats. The largest cut stone today is 36,853 carats.

Tourmaline

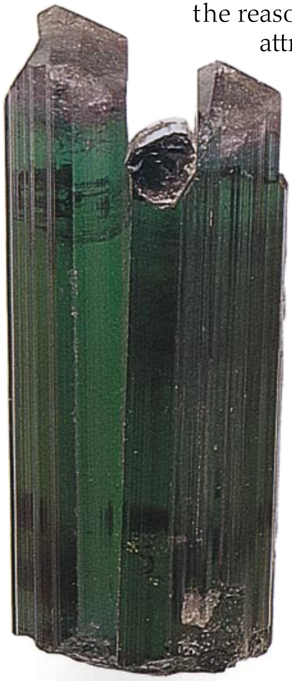
Tourmaline is a mineral with a complex chemistry. It crystallizes as prisms with flat or wedge-shaped terminations. Every crystal has a different structure at each end, sometimes indicated by different colors. This gives tourmaline an unusual electrical property. If a crystal is gently warmed, one end becomes positively charged and the other negatively charged, which is the reason for its tendency to attract dust.



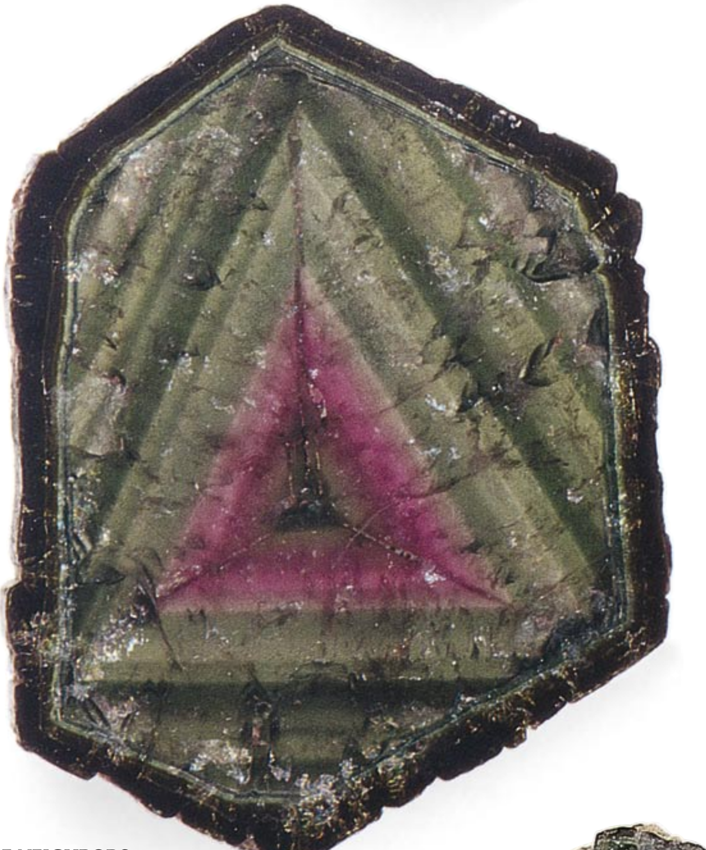
TOURMALINE CRYSTAL
Crystal system: trigonal; hardness: 7–7.5; specific gravity: 3–3.25.



MEDICINE OR MINERAL
Philosopher John Ruskin, shown here in 1885, wrote "the chemistry of tourmaline is more like a medieval doctor's prescription than the making of a respectable mineral!"

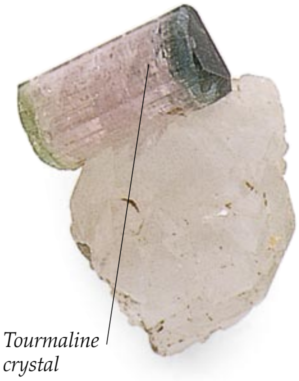


BLACK AND GREEN
Tourmaline is pleochroic, which means it is a different color when viewed down different axes (pp. 12–13). These green crystals would be almost black if viewed down the long axis.

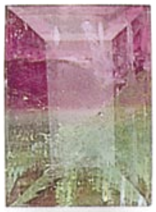


FRAMED UP
This slice across a tourmaline prism shows typical three-fold symmetry and a triangular cross-section. The zones of color illustrate how the crystal was built up in layers, each layer being a different phase of crystallization. The final shape of the crystal is controlled by the last phase, which in this case formed a hexagonal "frame."

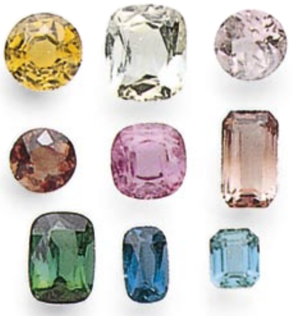
The growth rings seen in some crystals are similar to those of tree trunks



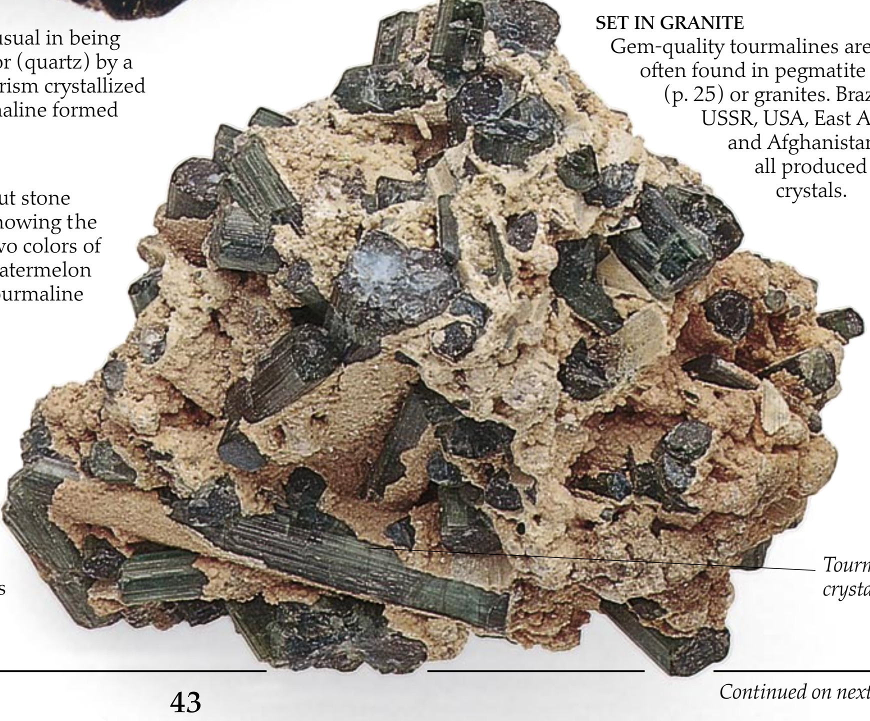
CLOSE NEIGHBORS
This tourmaline is unusual in being attached to its neighbor (quartz) by a prism face. The pink prism crystallized first, then green tourmaline formed the terminations.



Cut stone showing the two colors of watermelon tourmaline



MULTICOLORED
Tourmaline shows the greatest color range of any gemstone, and some crystals are themselves more than one color. Watermelon tourmaline has pink cores and green outer zones.



SET IN GRANITE
Gem-quality tourmalines are most often found in pegmatite veins (p. 25) or granites. Brazil, USSR, USA, East Africa, and Afghanistan have all produced fine crystals.

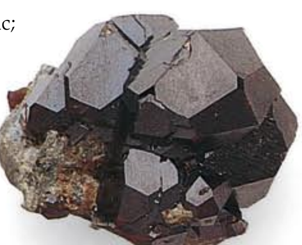
Continued from previous page

Garnet

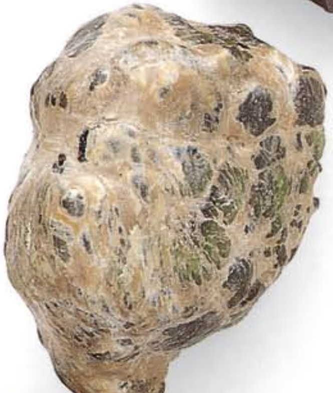
Garnet is the name of a family of chemically related minerals that includes almandine, pyrope, spessartine, grossular, and andradite. They can all be found as gemstones, the almandine-pyrope group being the most widely used. Because of the different chemical compositions, garnet occurs in most colors other than blue. Sources of gem-quality material include Czechoslovakia, South Africa, USA, Australia, Brazil, and Sri Lanka.

Ring set with almandine garnet



GARNET CRYSTALS
Crystal system: cubic; hardness: 6.5–7.5; specific gravity: 3.52–4.32.

Cut demantoid garnet



DEMANTOID
Emerald-green demantoid is the most prized of all the garnets. The finest stones come from the Ural Mountains in the USSR.

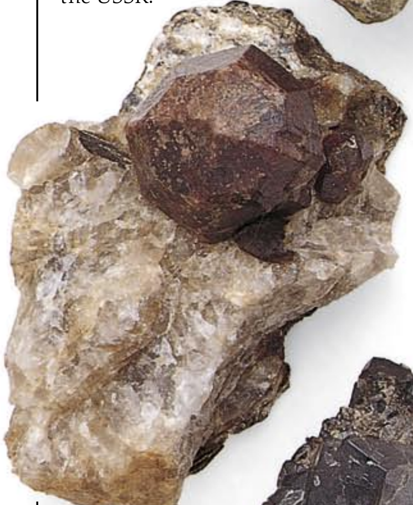
Cut pyrope garnet

PYROPE
The deep-red garnet, pyrope, was popular in the 19th century. Most stones came from Bohemia.

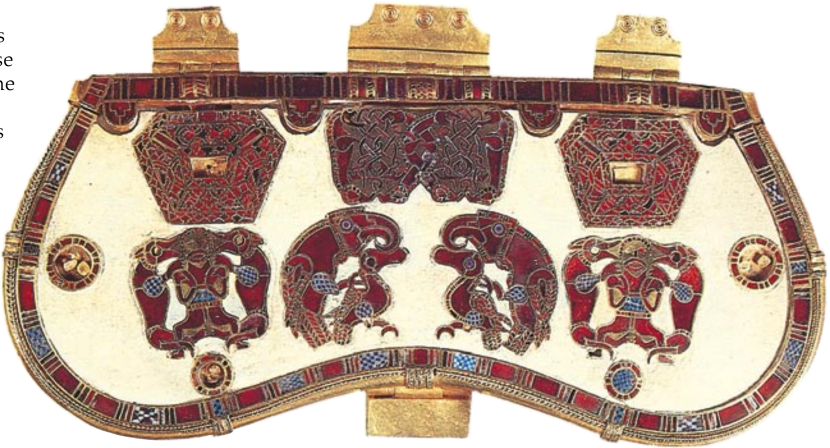
Spessartine cabochon

SPESSARTINE
The beautiful orange colors of spessartine are caused by manganese. Spessartine is not often seen in jewelry, as gem-quality crystals are rare.

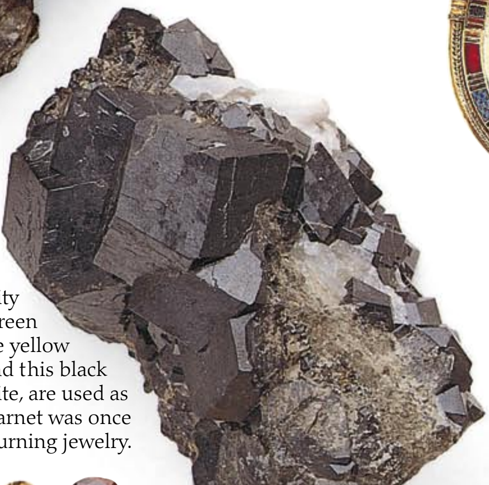
FRUITY NAME
"Garnet" may come from *pomum granatum*, Latin for pomegranate. The gem color of the almandine-pyrope group is similar to that of the pomegranate.



ALMANDINE
Garnet commonly crystallizes as icositetrahedrons, like these almandine crystals. Almandine usually has a very deep color so it is often cut as cabochons (p. 59) with the backs hollowed out to make it more transparent.



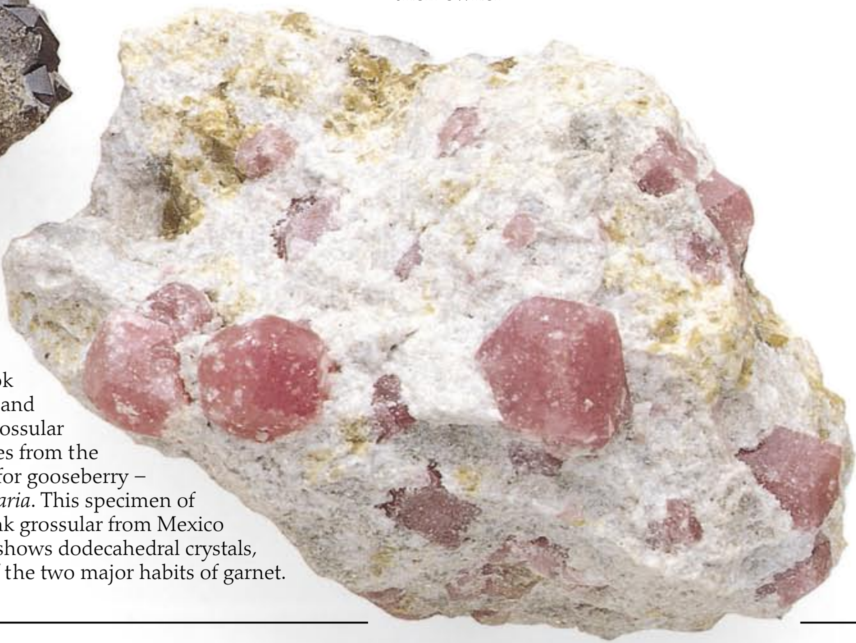
FIT FOR A KING
This fine 7th-century purse lid was among many garnet-set pieces found in an Anglo-Saxon royal burial ship in Sutton Hoo, Suffolk, England. The quality of the workmanship of all the pieces indicates the high status of their owner.



ANDRADITE
Most andradite garnet does not occur as gem-quality crystals. Only green demantoid, the yellow variety topazolite, and this black variety, melanite, are used as gemstones. Black garnet was once used as mourning jewelry.

Cut grossular garnets

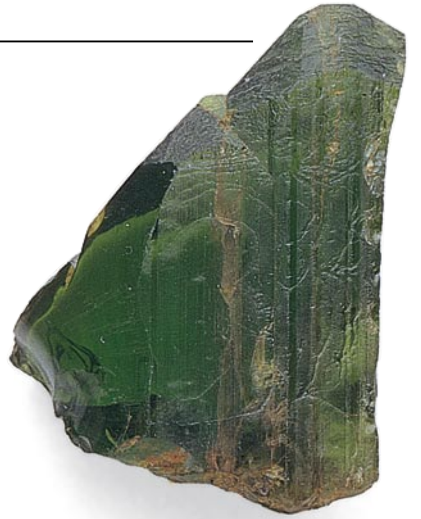
COLOR TRACES
Brilliant-green grossular contains trace amounts of vanadium, while the yellow and red stones contain iron. The red variety is known as hessonite.



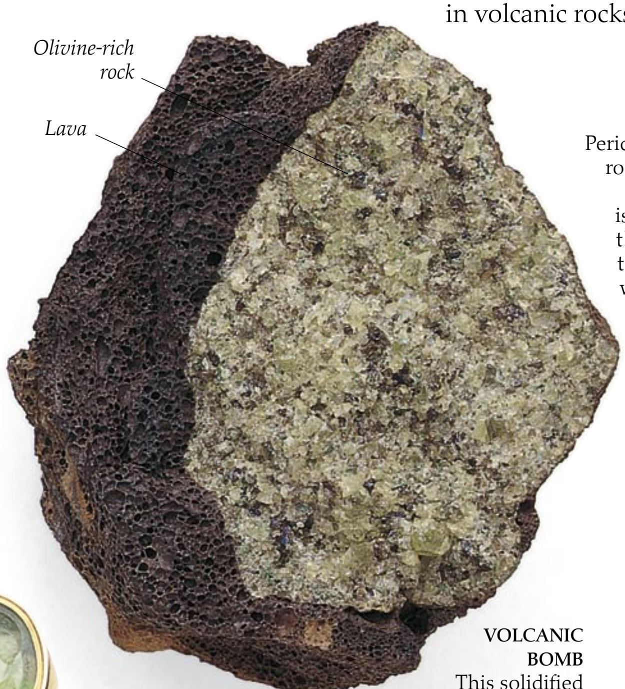
GROSSULAR
Some grossular garnet is said to look like gooseberries and the name grossular probably comes from the Latin for gooseberry – *grossularia*. This specimen of pink grossular from Mexico clearly shows dodecahedral crystals, one of the two major habits of garnet.

Peridot

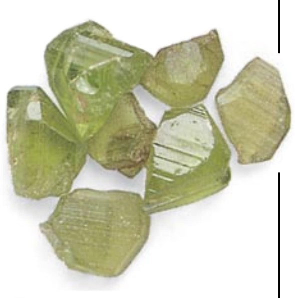
Peridot is a French word and may derive from the Arabic *faridat*, meaning a gem. It is the gem variety of the mineral olivine, a magnesium and iron silicate that is common in volcanic rocks.



PERIDOT CRYSTAL
Crystal system: orthorhombic; hardness: 6.5; specific gravity: 3.22–3.40.



VOLCANIC BOMB
This solidified lava contains fragments of rock rich in olivine. The lava came from deep within the earth, carrying the rock with it, and the whole piece was ejected through a volcano as a volcanic bomb.



ISLAND GEM
Peridot usually occurs in rocks intergrown with other minerals. The island of Zabargad in the Red Sea is one of the few places in the world where crystals with distinct faces, such as these, are found.

Cut peridot from Arizona

Cut peridot from Myanmar

Cut peridot from Norway

PERIDOT SUPPLIERS
The largest peridots come from Zabargad and Myanmar, but Arizona, Hawaii, and Norway have also supplied fine gems.

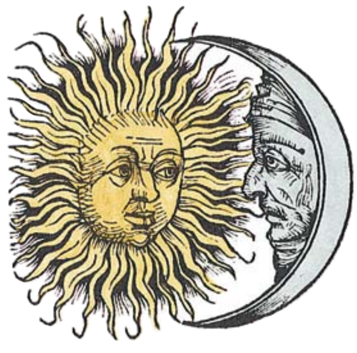
Ring set with peridot

NAME CHANGE
There have been peridot mines on the island of Zabargad in the Red Sea for a long time. The stones from here were known by the ancient Greeks as *topazos* (p. 42).

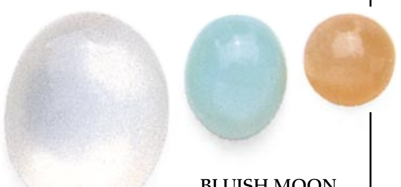
Moonstone

Moonstone is the best-known feldspar gem. Feldspars are common in rocks, but rarely of gem quality. There are two main groups: one which is rich in potash and includes the moonstones; one which is rich in soda and calcium and includes sunstone. They range in hardness from 6–6.5 and in specific gravity from 2.56–2.76.

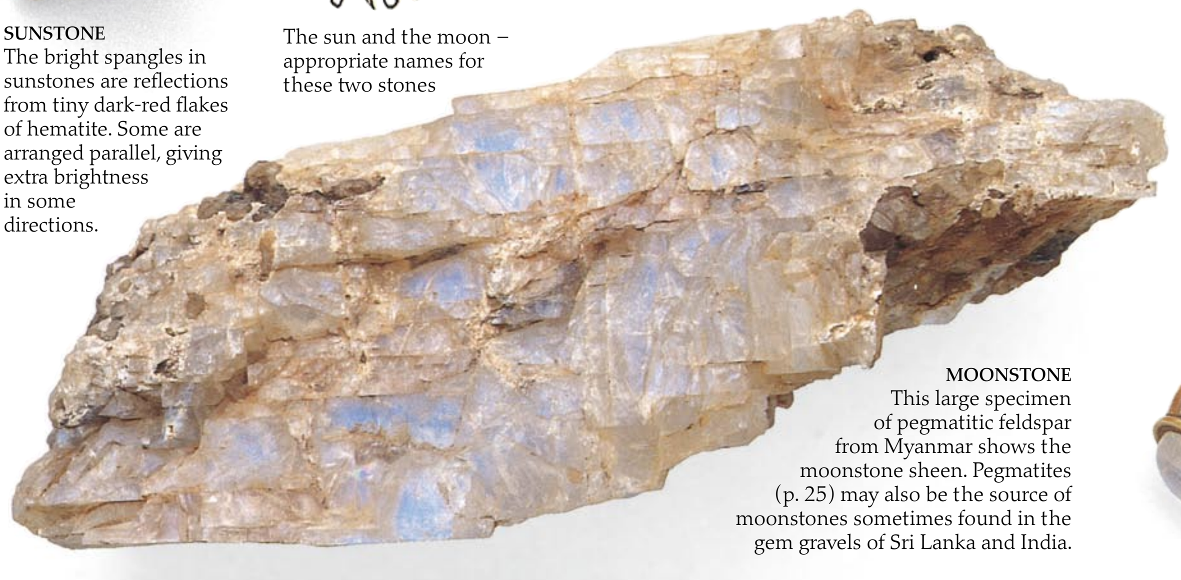
SUNSTONE
The bright spangles in sunstones are reflections from tiny dark-red flakes of hematite. Some are arranged parallel, giving extra brightness in some directions.



The sun and the moon – appropriate names for these two stones



BLUISH MOON
Most moonstones are colorless with a silvery or bluish sheen, but some varieties may be steely gray, orange pink, yellow, or pale green. The gray stones particularly may show good cat's-eyes (p. 59).



MOONSTONE
This large specimen of pegmatitic feldspar from Myanmar shows the moonstone sheen. Pegmatites (p. 25) may also be the source of moonstones sometimes found in the gem gravels of Sri Lanka and India.

Pin set with sunstone

Ring set with moonstone

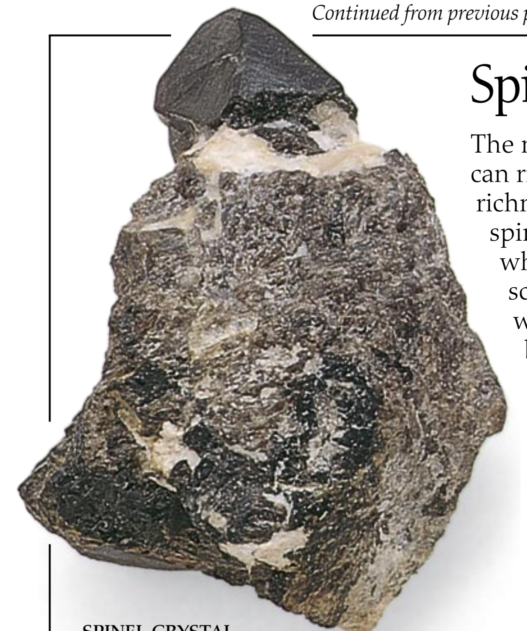
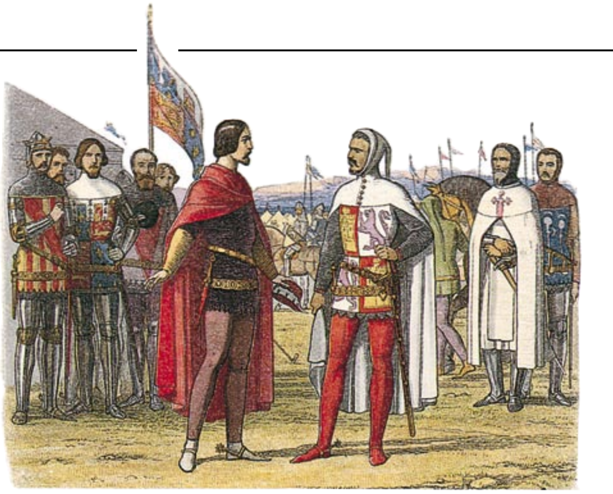
Continued from previous page

Spinel

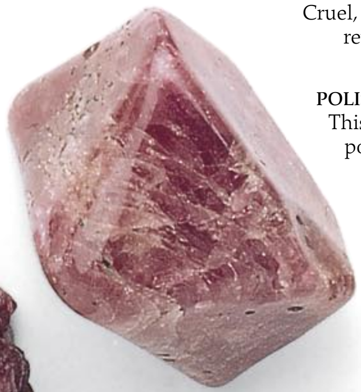
The most beautiful red and blue spinels can rival ruby and sapphire in their richness. Until the 19th century, red spinels were called balas rubies, which led to some confusion. The scientist Romé de l'Isle (p. 12) was the first to distinguish clearly between true ruby and red spinel. The term *balas* may relate to a source of these stones in Balascia, now called Badakhshan, in Afghanistan.



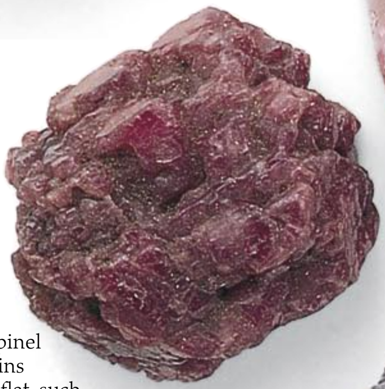
SPINEL CRYSTAL
Crystal system: cubic; hardness: 8; specific gravity: 3.5–3.7.



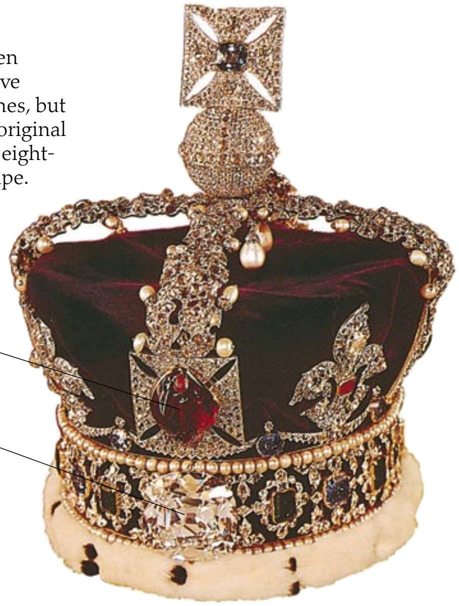
PRINCELY REWARD
The Black Prince, son of King Edward III of England, helped Pedro the Cruel, King of Castile, Spain, to win the Battle of Najera in 1367. He was rewarded with a balas ruby, now in the British imperial state crown.



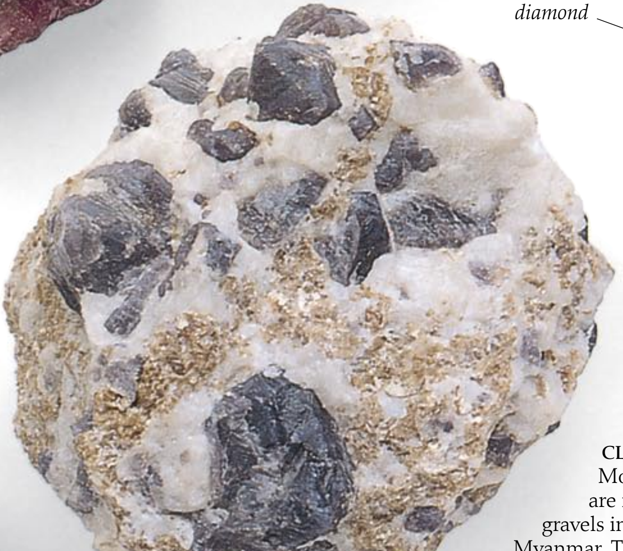
POLISHED OVER
This crystal has been polished to remove surface blemishes, but it still has its original octahedral (eight-faced) shape.



SMALL DISTORTION
Spinel usually crystallizes as octahedra. This specimen is a crystal aggregate (p. 22) of small distorted octahedra in parallel growth. Spinel often occurs as twins (p. 21), and when flat, such crystals are called macles.

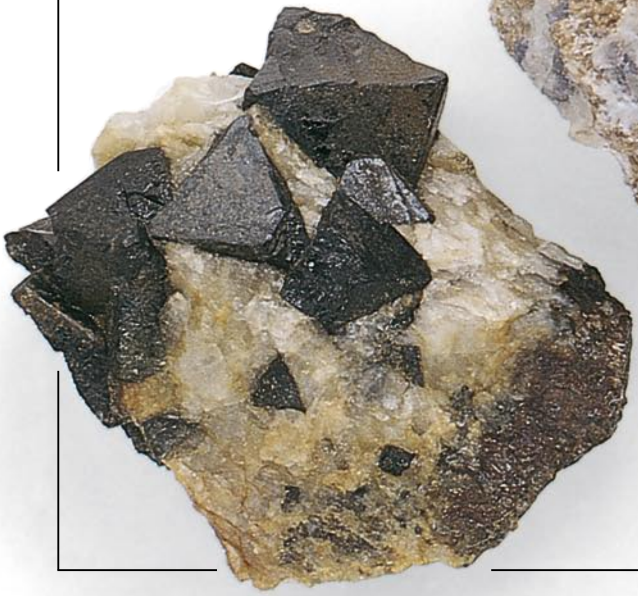


LYING IN STATE
The Black Prince's ruby in the British imperial state crown is really a 170-carat spinel, once called a balas ruby. It is mounted above another famous stone, the Cullinan II diamond (p. 35). The Timur ruby, which belongs to England's Queen Elizabeth II, is also a spinel.

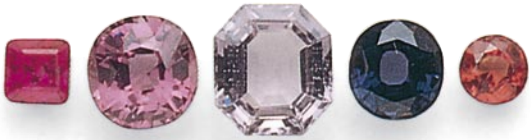


REFORMED CHARACTER
This specimen from Lake Baikal, USSR, contains octahedra of blue spinel set in a matrix, or network, of white calcite and shiny muscovite mica. Originally it was probably an impure limestone which completely recrystallized under moderate temperature and pressure.

CLOSE TO HOME
Most gem spinels are recovered from gravels in Sri Lanka and Myanmar. These Myanmar fragments are not very worn, indicating that they have not traveled far from their source.



THORNY CRYSTALS
These beautifully crystallized octahedra from Bodenmais in Germany are gahnite, a zinc-rich variety of spinel. They show the typical triangular-shaped crystal faces of spinel which may account for the possible derivation of its name from the Latin *spina*, meaning thorn.

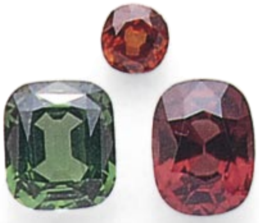


CRYSTAL COLORS
Pure spinel is colorless. The beautiful reds and pinks are due to small amounts of chromium in the crystals. Blues and greens are caused by iron and, rarely, by zinc.

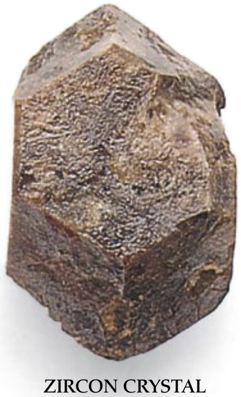
Zircon

The name zircon comes from the Arabic *zargoon*, meaning vermilion or golden-colored. Sri Lanka has been a source of zircons for 2,000 years, but today stones also come from Thailand, Australia, and Brazil. Colorless zircon looks like diamond in luster and fire and is used as a diamond simulant (p. 57), but it is softer and may look "sleepy" due to inclusions (p. 21) and double refraction (p. 19).

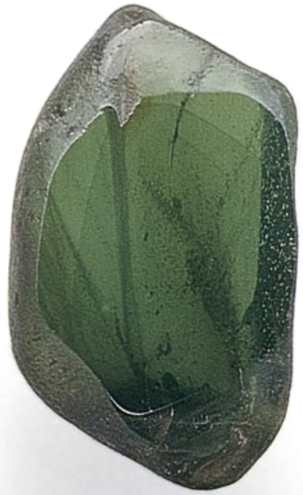
The color of red hyacinths may account for red zircon once being known as hyacinth



NATURAL COLORS
Zircon is zirconium silicate, colorless when pure, but found in a wide range of colors in nature because of different impurities.

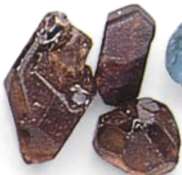


ZIRCON CRYSTAL
Crystal system: tetragonal; hardness: 6–7.5; specific gravity: 4.6–4.7.

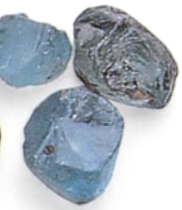


RADIOACTIVE
This exceptionally large pebble from Sri Lankan gem gravels shows a typical zircon color. Some zircons contain so much uranium and thorium that the radioactivity of these elements breaks down the crystal structure and the stone becomes amorphous, or noncrystalline.

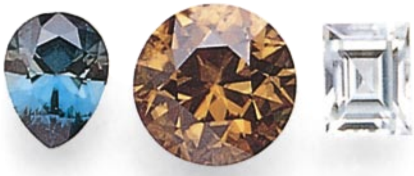
HEAT TREATMENT
Colorless, blue, and golden zircons can be produced by heating red-brown crystals. Heating in an oxygen-free atmosphere produces blue zircon; heating in air, i.e. with oxygen, produces a golden color. Some colorless stones are produced by both methods. These colors may fade but can be restored by reheating.



Natural brown zircon crystals



Heat-treated blue zircon crystals

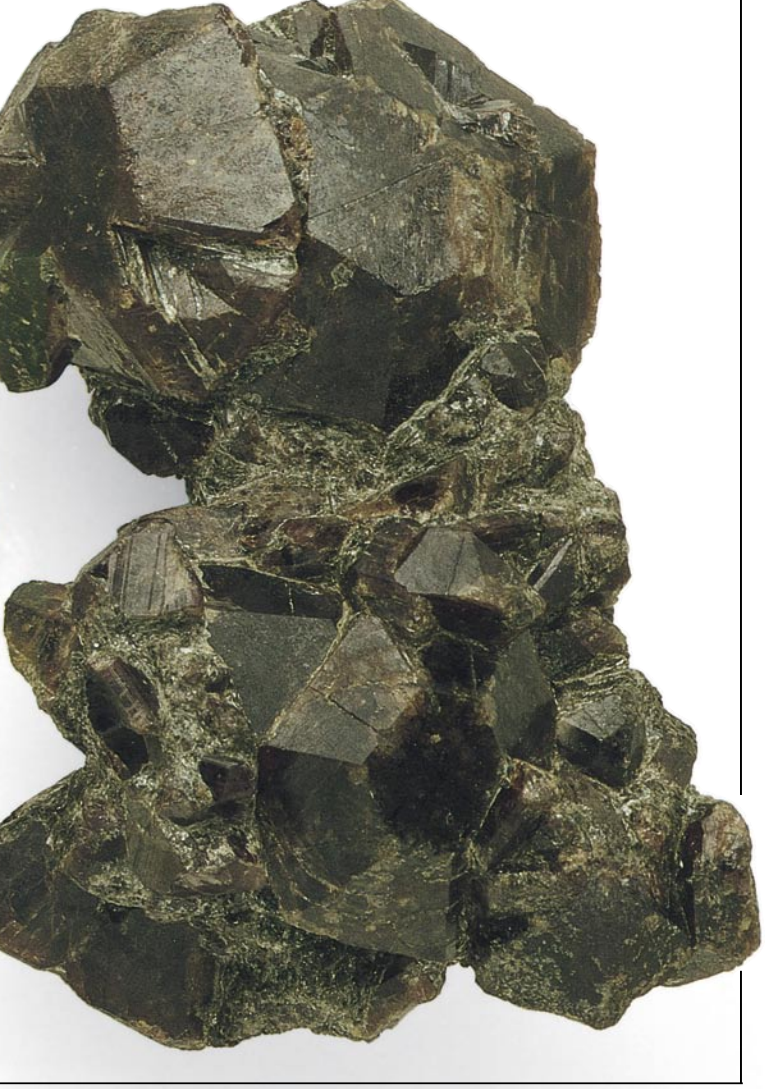


Stones cut from heat-treated zircon

Chrysoberyl

Gem chrysoberyl is exceeded in hardness only by diamond and corundum. The yellow, green, and brown colors are caused by iron or chromium. There are three varieties: clear yellow-green gems; cat's-eye, or cymophane, usually cut as cabochons to display the "eye" effect (p. 59); and alexandrite, famous for its dramatic color change. Sri Lanka and Brazil are sources for all three, but the best alexandrites come from the USSR.

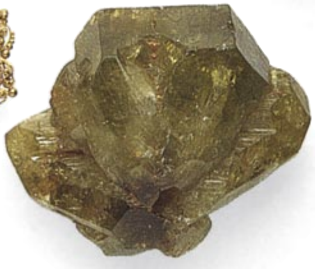
ALEXANDRITE
Alexandrite was discovered in the Ural Mountains, USSR, on the birthday of Czar Alexander II in 1830, hence the name. They appear a deep green in daylight and red in artificial light, matching the Russian imperial colors.



Cut yellow chrysoberyl

Cut alexandrite

POPULAR IN PORTUGAL
Yellow-green chrysoberyls were found in Brazil in the 18th century. These became very popular in Portuguese and Spanish jewelry.

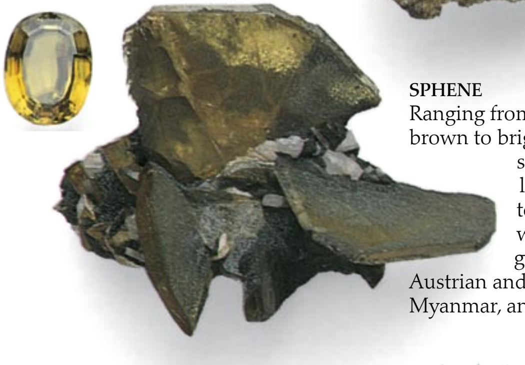


CHRYSOBERYL CRYSTAL
Crystal system: orthorhombic; hardness:8.5; specific gravity: 3.68–3.78.

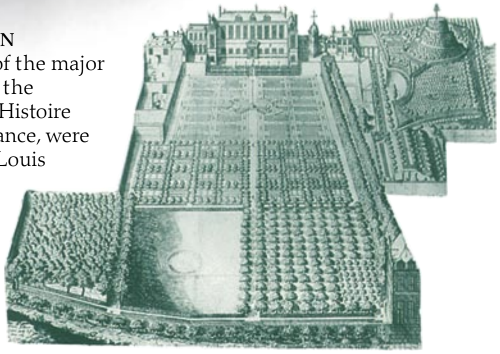
Collectors' items

With over 3,000 species of minerals to choose from, the potential number of gems would appear at first to be very large. But crucial factors such as hardness (pp. 18–19), durability, and rarity reduce the number of commercial gems to a few dozen. Many people collect rarities that are not in general circulation. They may seek the rare colors or exceptional sizes of common gems, or cut examples of minerals too soft or fragile to wear in jewelry. For example, blende and sphene are available in reasonable quantities but are too soft for constant wear. Benitoite is durable enough to be worn but is too rare to be generally available.

AXINITE
The most beautiful wedge-shaped crystals of brown axinite come from Bourg d'Oisans in France and display flashes of gray and violet in different directions. Although they were once extremely rare, crystals are being recovered more regularly from the Sri Lanka gem gravels.



SPHENE
Ranging from golden yellow brown to bright emerald green, sphene has great luster and fire but is too soft for general wear. The finest gems come from the Austrian and Swiss Alps, Myanmar, and California.



FRENCH COLLECTION
The first specimens of the major mineral collection in the Muséum National d'Histoire Naturelle in Paris, France, were brought together in Louis XIII's pharmacy and botanical gardens. This engraving shows the gardens as they were in 1636, seven years before the king died.

ALPINE EXPERTS
Many fine crystals are collected from crystal-lined clefts in the Alps by people known as *strahlern. Strahlern* are experienced mountaineers but also talented mineral collectors, usually with great knowledge of a particular Alpine area.

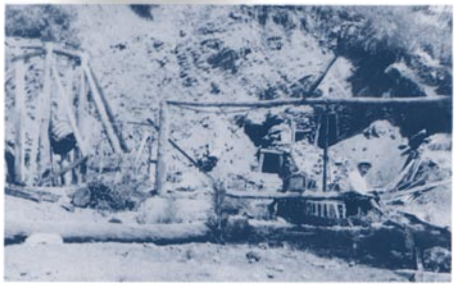
TANZANITE
The purplish blue gem variety of the mineral zoisite is tanzanite. It was found in northern Tanzania in 1967 and is remarkable for its displays of rich blue, magenta, and yellowish gray. Many crystals are greenish gray and are heat-treated to the more attractive blue.

DANBURITE
The mineral danburite is named after Danbury, Connecticut, where it was first found as colorless crystals in a pegmatite (p. 25). Fine yellow stones come from Madagascar and Myanmar, and colorless stones from Japan and Mexico.

CORDIERITE
Fine, gem-quality cordierite comes from Sri Lanka, Myanmar, Madagascar, and India. Cordierite is exceptional in showing very strong pleochroism (p.36), from deep purplish blue in one direction, to pale yellowish gray in another. This pleochroism was used by the Vikings for navigating their long boats (p. 60) and has also led to the crystals being called water sapphires.

BENITOITE

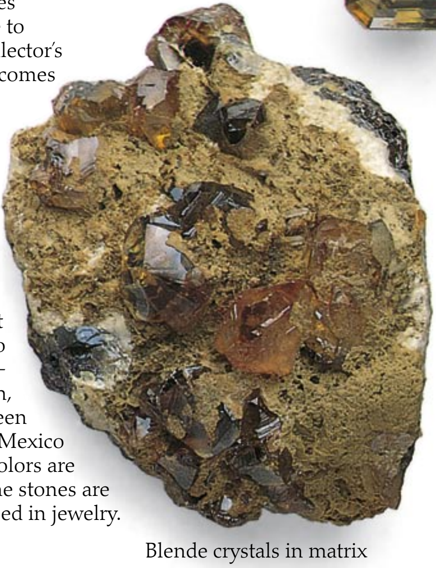
The color of benitoite crystals can be compared with that of fine sapphires (pp. 36–37). They display similar fire to diamonds (pp. 34–35), but remain collector's stones because of their rarity. Benitoite comes from localities in San Benito County, California, after which it is named (p. 11).



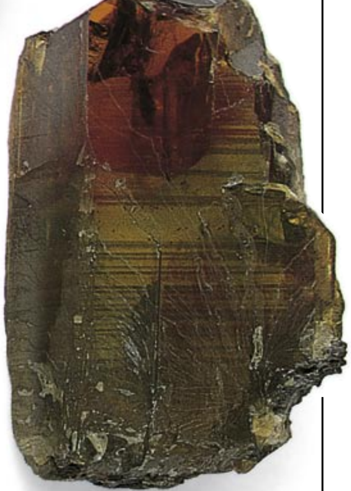
The San Benito mine in 1914 showing the open cut and an ore bucket on the left

BLENDE

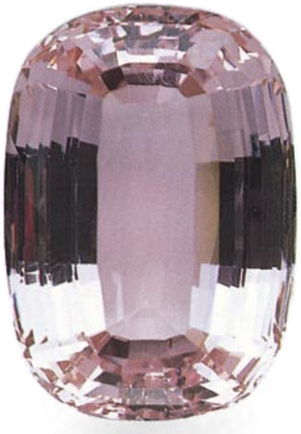
The popular name for sphalerite, the world's major source of zinc, is blende. Normally it is opaque gray to black, but gem-quality reddish brown, yellow, and green crystals come from Mexico and Spain. The rich colors are very attractive, but the stones are too soft to be used in jewelry.



Blende crystals in matrix



Rough blende crystal



Cut kunzite

Cut pale-green spodumene

Kunzite crystal

SPODUMENE

Magnificent crystals of spodumene come from Brazil, California, and Afghanistan. Fine gems weighing hundreds of carats have been cut from pale-green and yellow crystals, and from the pink variety kunzite, named after G. F. Kunz. Small crystals of a rare, emerald-green variety called hiddenite are found in North Carolina and Sri Lanka.

George Frederick Kunz, an author on gems, who worked for the New York jewelers Tiffany's early this century

GOLDNEY GROTTO

Precious stones and corals are among items collected to cover the walls and pillars of this underground grotto. It was built between 1737 and 1764 near Bristol, England.

SCAPOLITE

Myanmar and East Africa are sources of scapolite gems. They occur in pastel shades of yellow, pink, purple, and fine cat's-eyes (p. 59).

SINHALITE

Originally traded as peridot from Sri Lanka, sinhalite was proved in 1952 to be a new species. Mineralogists in the British Museum named it after an old name for Sri Lanka – Sinhala.

FIBROLITE

This bluish violet stone of 19.84 carats is fibrolite, a rare variety of the mineral sillimanite. It comes from Myanmar and is one of the largest in the world. Andalusite has the same chemical composition – aluminum silicate – but a different structure. The gem-quality stones show bold red and green pleochroic colors. Fine examples come from Brazil and Sri Lanka.

Cut fibrolite

Cut andalusite

Stones for carving

Microcrystalline rocks and minerals have been used in decoration for thousands of years. The best known are the jades, lapis lazuli, and turquoise, and there are many more which are suitable for carving work. Ancient civilizations such as the Egyptians, Chinese, and Sumerians used jade, lapis, and turquoise to make jewelry. South American Indians and the Maoris of New Zealand have been carving turquoise and jade for centuries.

MALACHITE
Malachite is a vivid green copper mineral. It is often found as kidney-shaped masses surrounded by bands of color. It is 4 on the hardness scale (pp. 18–19) and has a specific gravity of 3.8. Zaire, Zambia, Australia, and the USSR are the main sources.

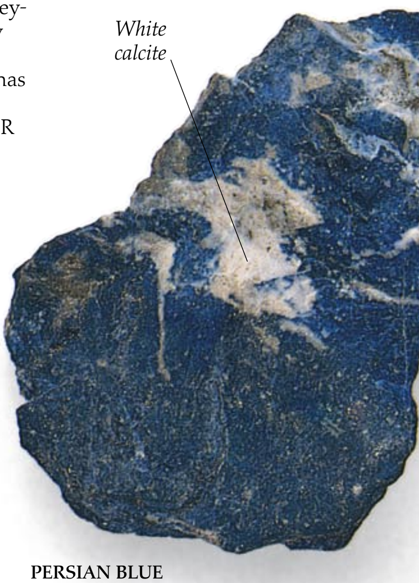
TURQUOISE TRADITION
Traditional Indian jewelry has been made for thousands of years in the southwestern USA, where most turquoise is still produced.

Turquoise

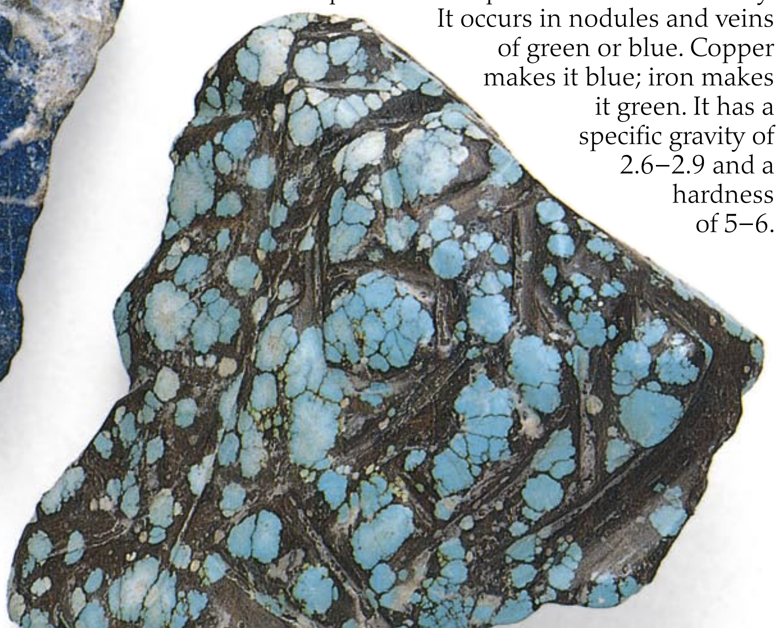
The word *turquoise* comes from the French *pierre turquoise*, meaning stone of Turkey; in the past most turquoise was sold in Turkey. It occurs in nodules and veins of green or blue. Copper makes it blue; iron makes it green. It has a specific gravity of 2.6–2.9 and a hardness of 5–6.

Lapis lazuli

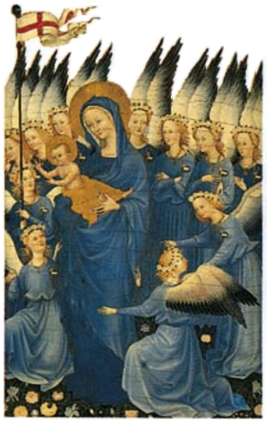
Lapis lazuli is not a single mineral but a rock consisting of blue lazurite with variable amounts of calcite and pyrite. The best, from Afghanistan, consists mostly of lazurite and is deep blue. It is 5.5 on Mohs' hardness scale and has a specific gravity of 2.7–2.9. There are other sources in the Soviet Union and Chile.



PERSIAN BLUE
The name lapis lazuli is derived from the Persian word *lazhward*, meaning blue. The blue color is caused by sulfur which is an essential part of its composition.



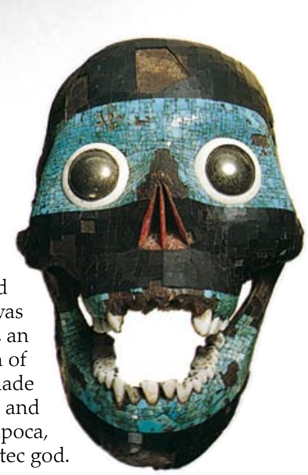
NATURAL MOSAIC
Turquoise is rare in large masses and is more often found forming mosaics. The finest blue turquoise comes from Iran (previously called Persia), where it has been used in decoration for almost 6,000 years.



MEDIEVAL PAINTING
In medieval times lapis lazuli was crushed and purified to make the paint pigment ultramarine. It was used to paint the Wilton Diptych, a detail of which is shown here. This famous altarpiece is now in the National Gallery in London, England.

POPULAR JEWEL
Lapis lazuli has been used extensively for beads and other pieces of jewelry.

Blue Persian turquoise engraved and inlaid with gold

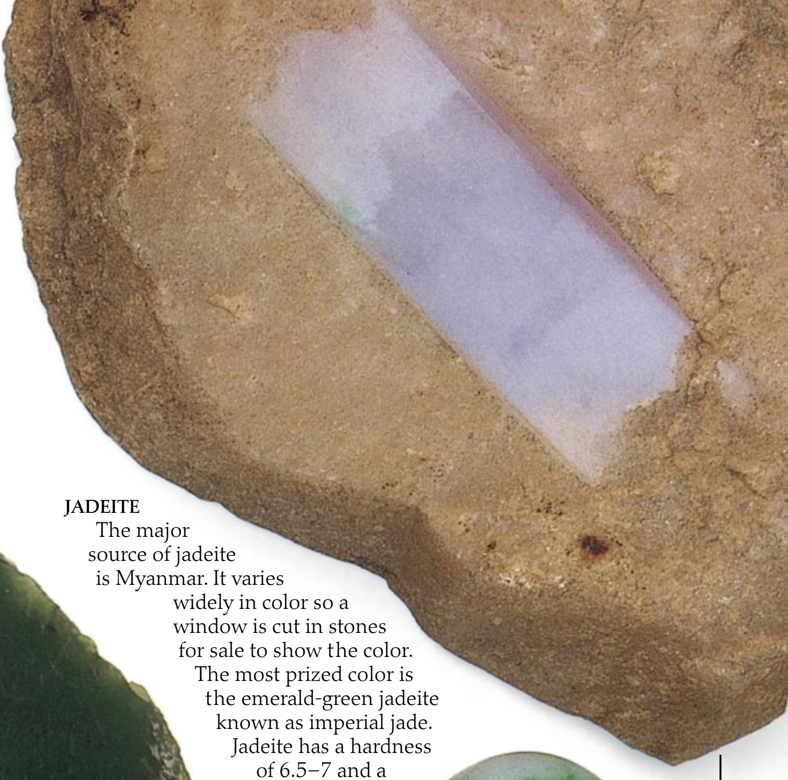


ANCIENT SKULL
This mask, shaped around a human skull, was made by the Aztecs, an ancient civilization of Central America. It is made of turquoise and lignum, and may represent Tezcatlipoca, an important Aztec god.

Jade

The Spanish conquerors of Mexico believed that the Indians' green stones would cure kidney ailments. They called them kidney stones or *piedras de hijadas* and from this the word *jade* was derived. In Europe, the name was then given to material of the same color and hardness which was imported from China. It was only in 1863 that they were proved to be two different minerals now called jadeite and nephrite.

LIFE JACKET
The ancient Chinese believed that jade had the power to give life and used it to try to preserve the dead. They linked plates of nephrite around the corpse to make a funeral suit. This one belonged to a princess of the 2nd century B.C. and is linked with gold.



JADEITE
The major source of jadeite is Myanmar. It varies widely in color so a window is cut in stones for sale to show the color. The most prized color is the emerald-green jadeite known as imperial jade. Jadeite has a hardness of 6.5–7 and a specific gravity of 3.3–3.5.

Jadeite fashioned into a ball

NEPHRITE
Nephrite is made of interlocking grains, making the stone tough. The "greenstone" used by the Maoris of New Zealand is nephrite. It has a hardness of 6.5 and a specific gravity of 2.9–3.1.

Nephrite snail designed by the famous Russian jeweler Fabergé

CHINESE CAMEL
This nephrite camel was carved in China. White and cream nephrites contain very little iron. More iron causes the spinach-green stones of the USSR, Canada, and New Zealand and the black jade of South Australia.

Other stones

Many other stones are popular for carving, mainly because of their color. These include malachite, serpentine, blue john, and rhodonite as well as marbles and alabaster.

RHODONITE
The bright pink color of rhodonite (*rhodo* means pink) is caused by manganese. It has a hardness of about 6 and is used for carving and inlays. Sources of gem material include USSR, Canada, and Australia.

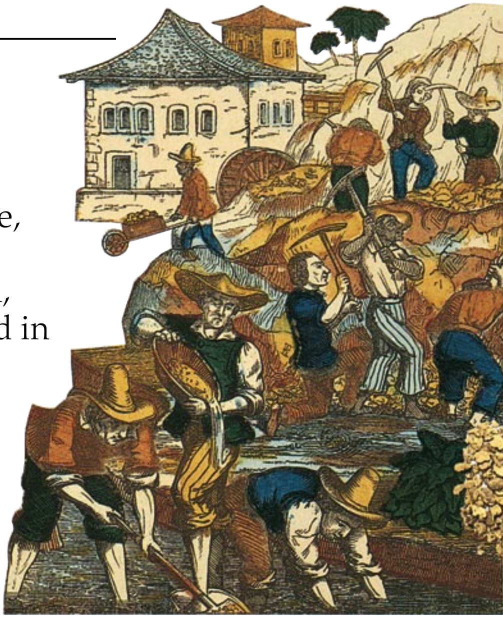
SERPENTINE
The patterns in serpentine often look like snake-skin, and carvers can use these to create works of art. Some is soft and easy to carve, but the yellow-green variety bowenite, a favorite of Chinese carvers, is harder – up to 6 on Mohs' scale.

BLUE JOHN
The distinctive purple and pale yellow banded fluorite called blue john comes from Derbyshire in England. It is fragile, so is usually bonded with resins to make it easier to work and harder-wearing.

19th-century blue john vase

Precious metals

GOLD, SILVER, AND PLATINUM are crystalline, but single crystals are rarely found. Gold and silver were among the earliest metals worked, over 5,000 years ago. Platinum was first noted in 1735 as a white metal used by the Chibcha Indians of Colombia, and today it is more valuable than gold and silver. All three metals are useful because they are relatively soft and easy to work. They are difficult to destroy and have high SGs (p. 18).

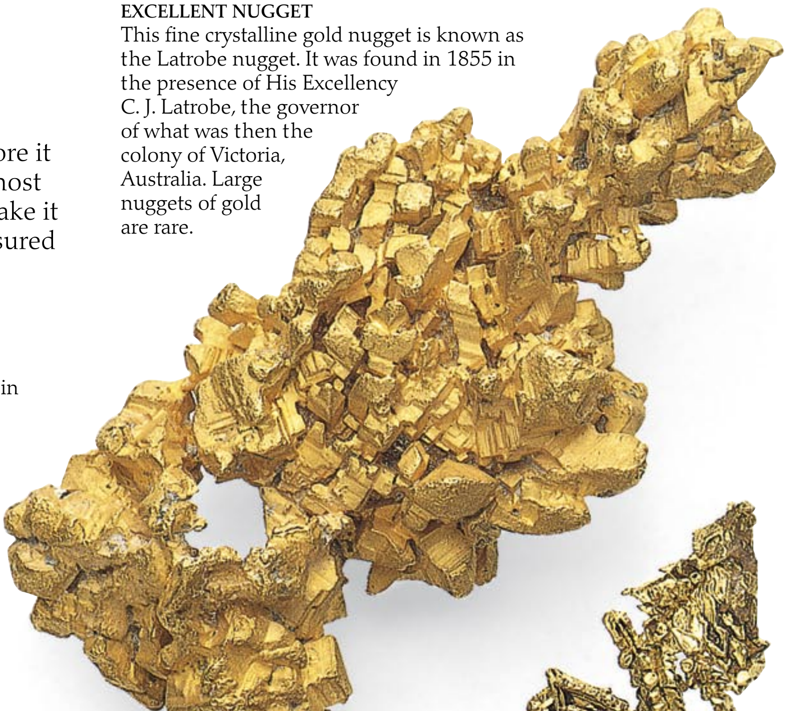


CALIFORNIA GOLD RUSH
The desire for gold has driven people to inhabit areas of the earth from the frozen Arctic to the scorching desert. Gold seekers rushed to California in 1848 and many became rich. Most of the gold was recovered from placer deposits by panning (p. 25).

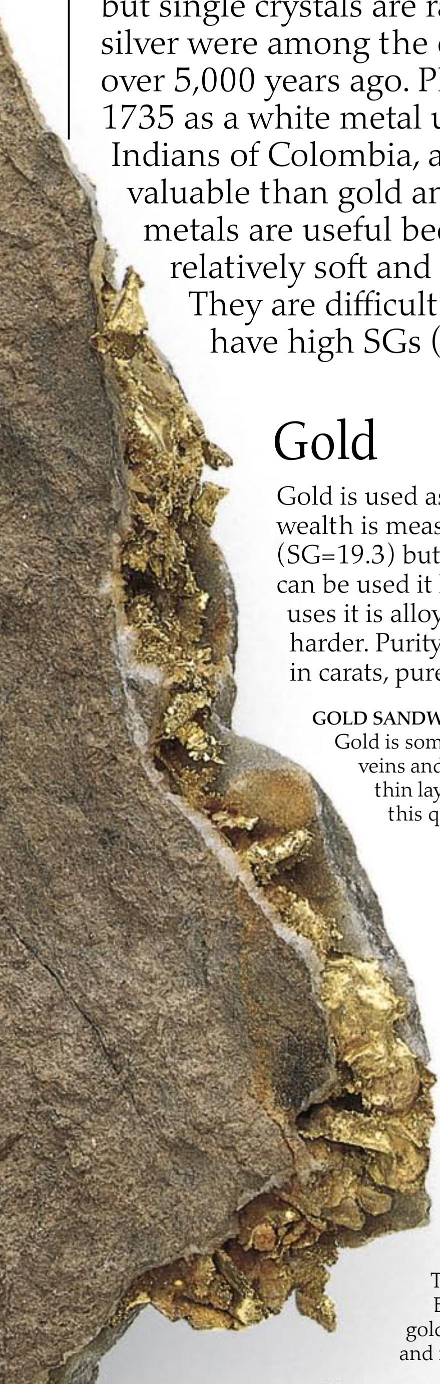
WELL PLACED
These are deposits of erosion debris from gold-bearing rock. Small particles of gold can be recovered from placer deposits by washing away the sand and gravel.

Gold

Gold is used as a standard against which wealth is measured. Pure gold is a dense (SG=19.3) but soft (H=2.5–3) metal. Before it can be used it has to be refined, and for most uses it is alloyed with other metals to make it harder. Purity of gold for jewelry is measured in carats, pure gold being 24 carats.



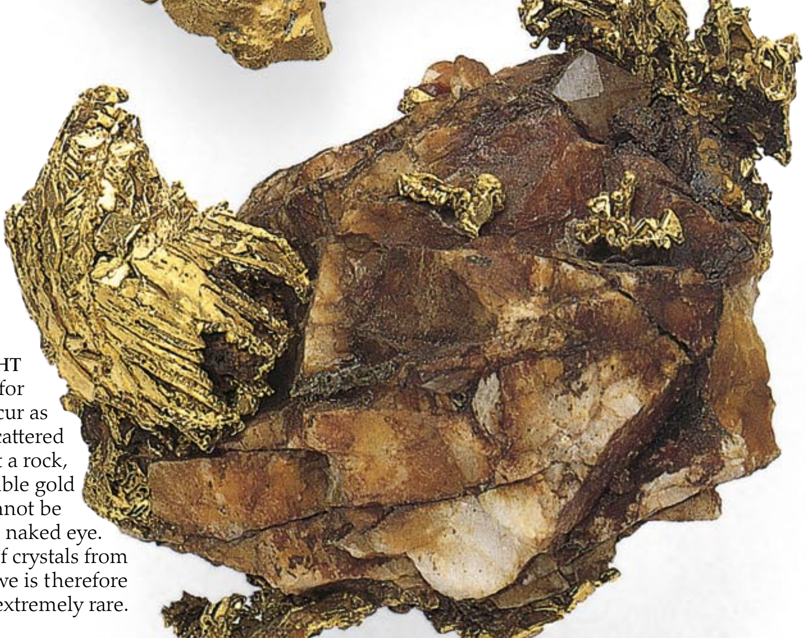
EXCELLENT NUGGET
This fine crystalline gold nugget is known as the Latrobe nugget. It was found in 1855 in the presence of His Excellency C. J. Latrobe, the governor of what was then the colony of Victoria, Australia. Large nuggets of gold are rare.



GOLD SANDWICH
Gold is sometimes found concentrated in veins and associated with quartz. A wafer-thin layer of crystalline gold can be seen in this quartz vein from New Zealand.

WORTH ITS WEIGHT
The famous golden Buddha of Bangkok is 5.5 tonnes of solid gold. It is worth over $50 million and is the most valuable religious item in the world.

BUILT ON GOLD
Between 1700 and 1900, the Asante kingdom dominated the area of Africa now known as Ghana. Its power was mostly founded upon its gold resources. Gold dust was the currency for internal trade. This lion ring is from the Asante kingdom:



RARE SIGHT
It is usual for gold to occur as fine grains scattered throughout a rock, or as invisible gold that cannot be seen by the naked eye. This group of crystals from Zimbabwe is therefore extremely rare.

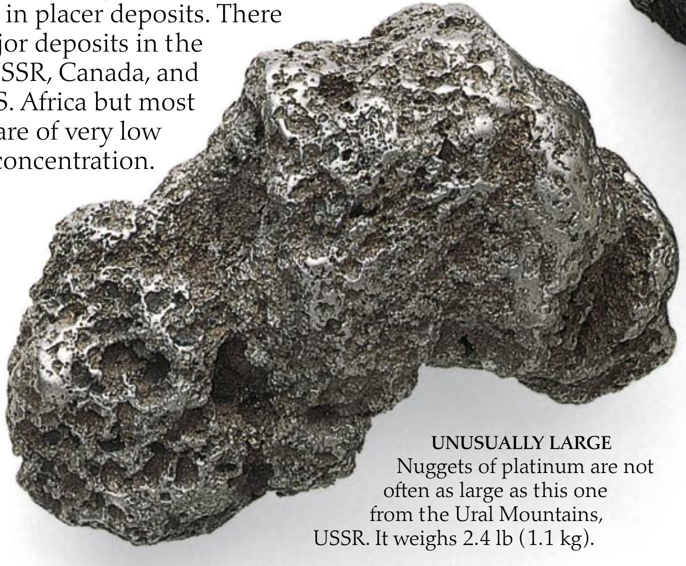
Platinum

Platinum plays a key role in modern technology. It is used as a standard weight, for surgical instruments, and of course in jewelry. The name is derived from *platina*, meaning little silver. Platinum is often found in granules or small nuggets in placer deposits. There are major deposits in the USSR, Canada, and S. Africa but most are of very low concentration.

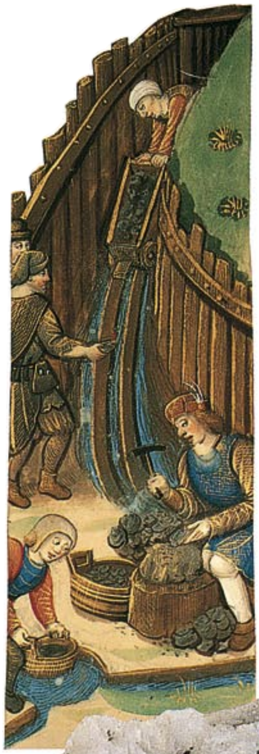
ROUNDED
Platinum is quite soft (H=4–4.5) so it is unusual to find sharp crystals. These cubic crystals come from Sierra Leone (West Africa).

CROWN OF PLATINUM
The crown of Queen Elizabeth the Queen Mother is made of platinum. It is part of the British Crown Jewels.

RICH LAYER
This piece of platinum-bearing pyroxenite comes from a layer of igneous rock in South Africa called the Merensky reef. This layer is only about 12 in (30 cm) thick but is very rich in platinum.



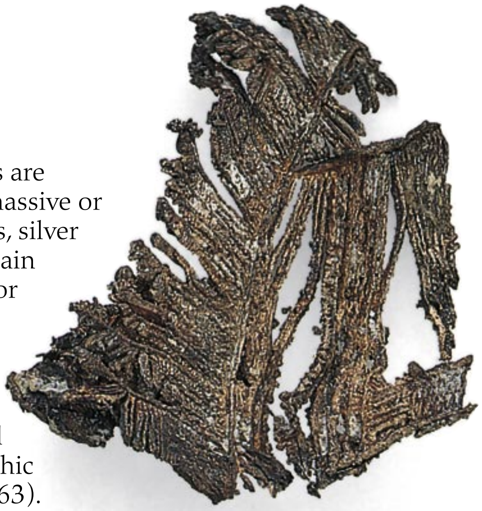
UNUSUALLY LARGE
Nuggets of platinum are not often as large as this one from the Ural Mountains, USSR. It weighs 2.4 lb (1.1 kg).



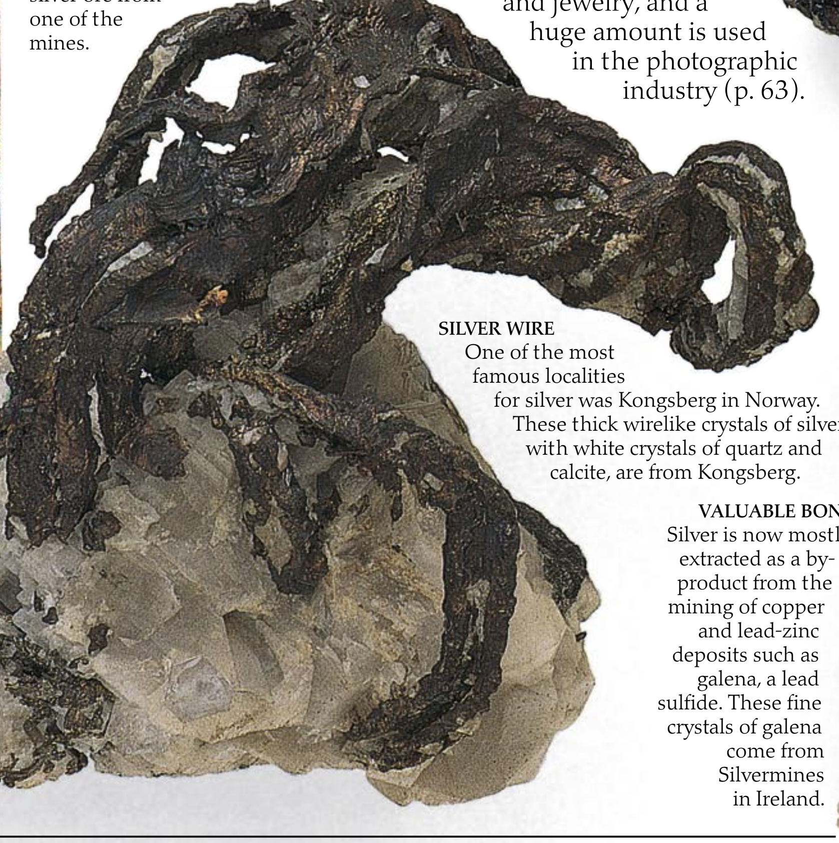
MEDIEVAL MINE
In medieval times the area around Sainte Marie, Alsace, France, was one of the richest silver-mining areas in Europe. This illustration from a medieval manuscript shows miners removing silver ore from one of the mines.

Silver

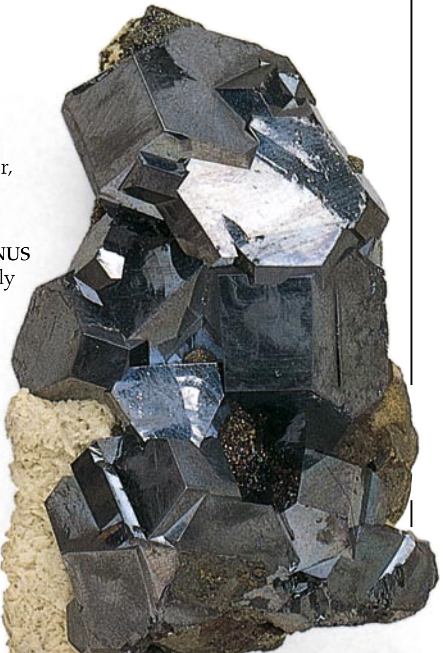
Crystals of silver are rare, but cubic crystals are occasionally found. Silver usually occurs massive or as thick wiry aggregates. In medieval times, silver was more valuable than gold. It was the main metal used for money and was also used for fine metalwork, having a hardness of only 2.5–3. Today, metallic silver is used in electronics, silver plating, and jewelry, and a huge amount is used in the photographic industry (p. 63).



IN NEED OF A POLISH
This dendritic growth (p. 23) of silver crystals is slightly tarnished. It comes from the Huantajaya mines, in Chile.



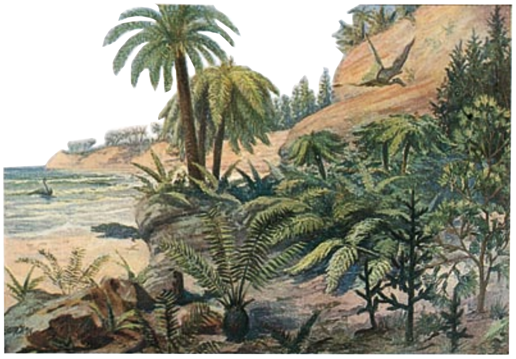
SILVER WIRE
One of the most famous localities for silver was Kongsberg in Norway. These thick wirelike crystals of silver, with white crystals of quartz and calcite, are from Kongsberg.



VALUABLE BONUS
Silver is now mostly extracted as a by-product from the mining of copper and lead-zinc deposits such as galena, a lead sulfide. These fine crystals of galena come from Silvermines in Ireland.

Animal and vegetable

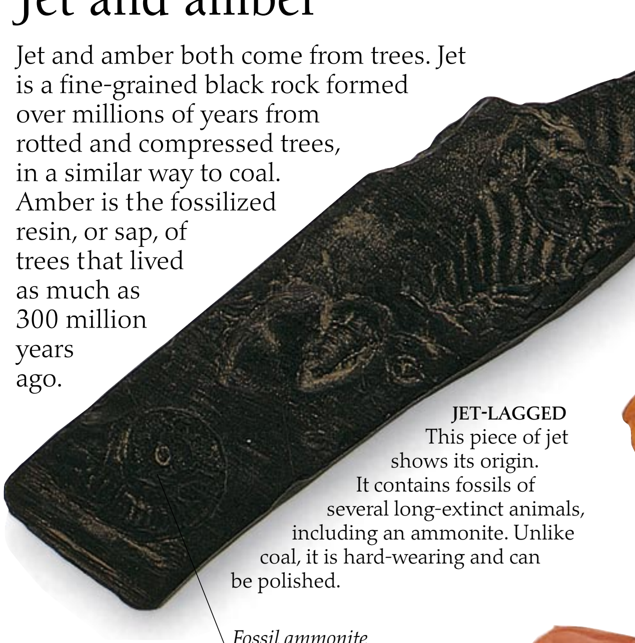
GEMS DERIVED FROM ANIMALS AND PLANTS are described as organic. They include amber, jet, coral, pearl, and shell. They are not as hard (4 or less) or as dense (1.04 – amber; 2.78 – pearl) as gemstones but have been popular for thousands of years because of their beauty. Beads of shell and amber have been found in ancient graves dating from 2000 B.C. Pearls have long had great value as symbols of beauty and purity. The Roman emperor Julius Caesar is said to have paid the equivalent of about $250,000 for a single pearl.



PREHISTORIC GEMS
In the Jurassic period, 160 million years ago, dinosaurs and other giant reptiles lived among the trees, which produced amber and jet.

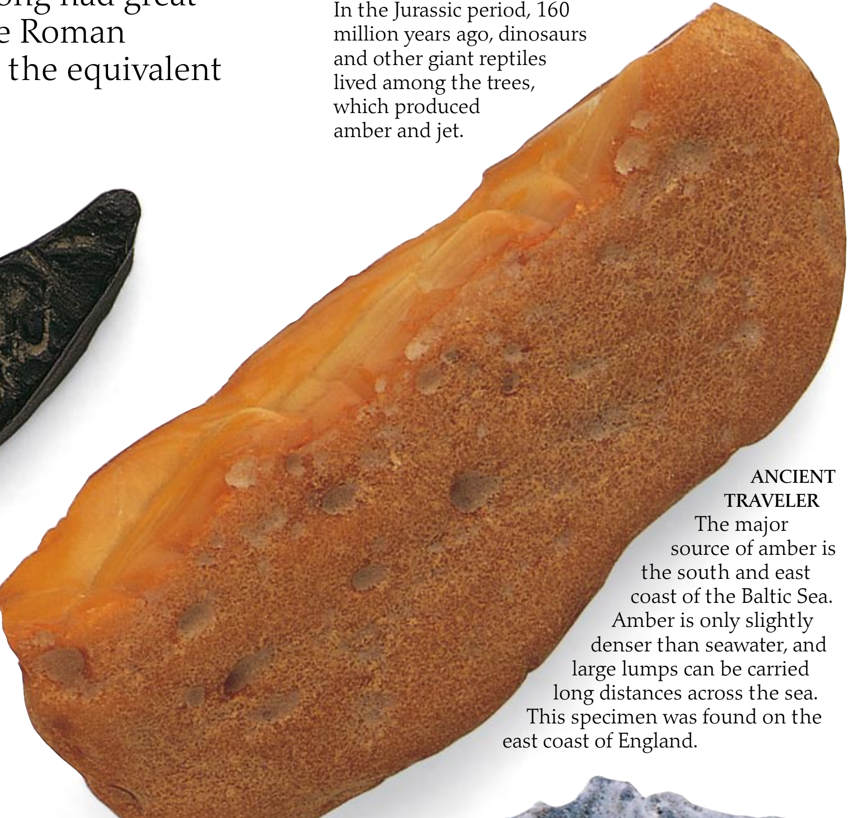
Jet and amber

Jet and amber both come from trees. Jet is a fine-grained black rock formed over millions of years from rotted and compressed trees, in a similar way to coal. Amber is the fossilized resin, or sap, of trees that lived as much as 300 million years ago.



JET-LAGGED
This piece of jet shows its origin. It contains fossils of several long-extinct animals, including an ammonite. Unlike coal, it is hard-wearing and can be polished.

Fossil ammonite

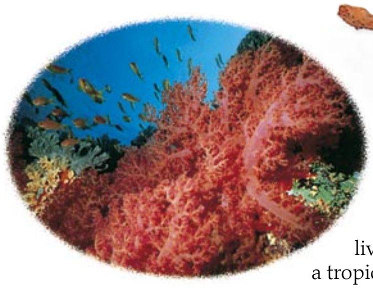


ANCIENT TRAVELER
The major source of amber is the south and east coast of the Baltic Sea. Amber is only slightly denser than seawater, and large lumps can be carried long distances across the sea. This specimen was found on the east coast of England.

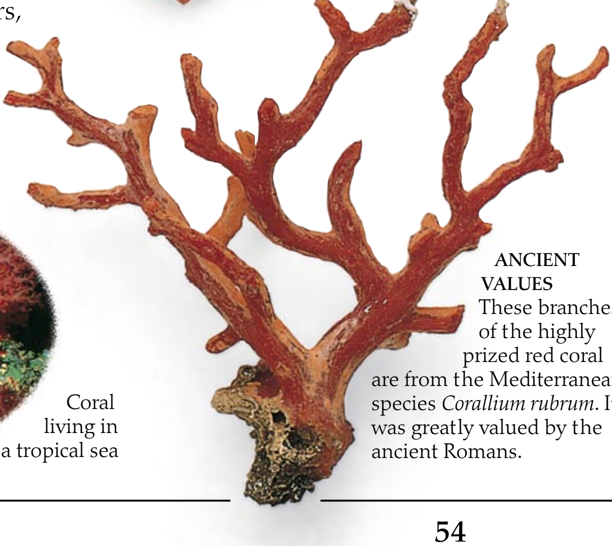
Coral

Coral is a skeleton of calcium carbonate made by colonies of soft-bodied animals which live in tropical or subtropical waters. The range of colors, from black to blue to cream to red, is due to different growth conditions and organic contents.

Carving from Mediterranean coral of a monkey clinging to a branch



Coral living in a tropical sea

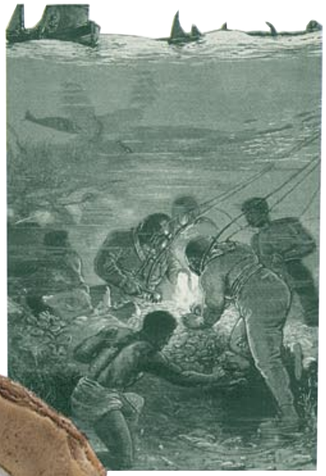


ANCIENT VALUES
These branches of the highly prized red coral are from the Mediterranean species *Corallium rubrum*. It was greatly valued by the ancient Romans.

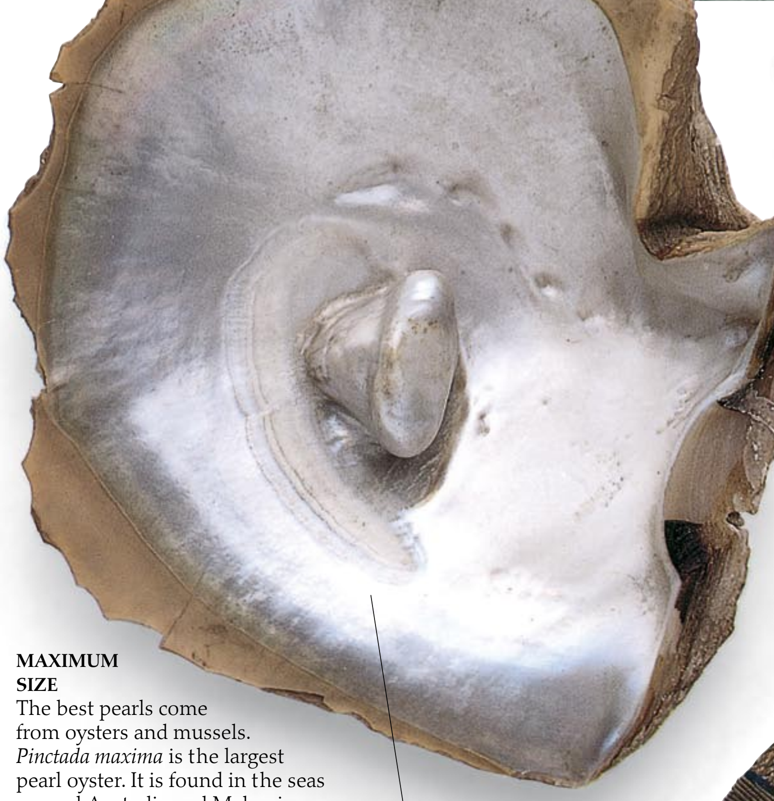
NECKLACE MATERIAL
This blue coral comes from the species *Heliopora caerulea* which grows in the seas around the Philippines. It is often cut into beads for necklaces.

Pearl and shell

The sheen on pearls and the inside of some shells is caused by light reflecting on tiny plates of calcium carbonate called nacre. Pearls, found in some marine and freshwater shells, form when a foreign body such as a sand grain becomes lodged inside the shell. To stop the irritation, the animal slowly surrounds the grains with nacre.



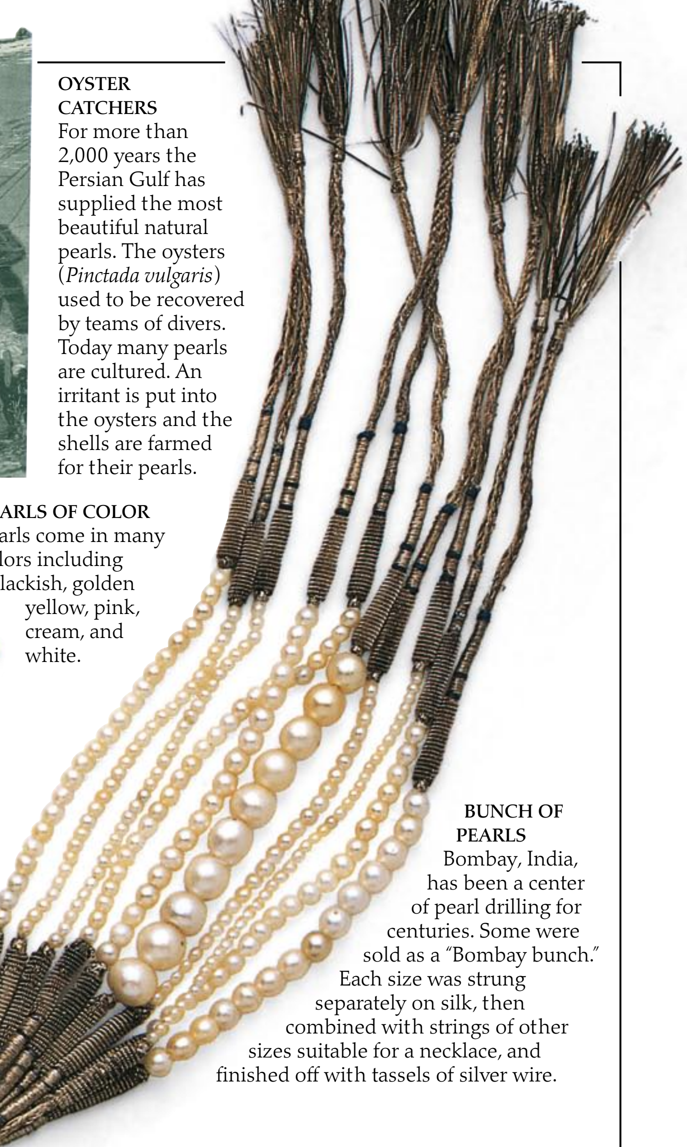
OYSTER CATCHERS
For more than 2,000 years the Persian Gulf has supplied the most beautiful natural pearls. The oysters (*Pinctada vulgaris*) used to be recovered by teams of divers. Today many pearls are cultured. An irritant is put into the oysters and the shells are farmed for their pearls.



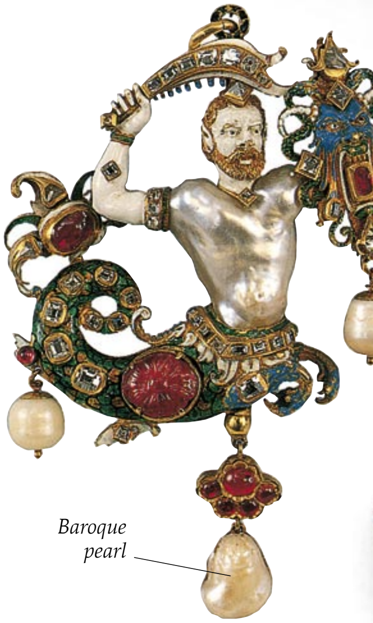
MAXIMUM SIZE
The best pearls come from oysters and mussels. *Pinctada maxima* is the largest pearl oyster. It is found in the seas around Australia and Malaysia.

Mother-of-pearl

PEARLS OF COLOR
Pearls come in many colors including blackish, golden yellow, pink, cream, and white.



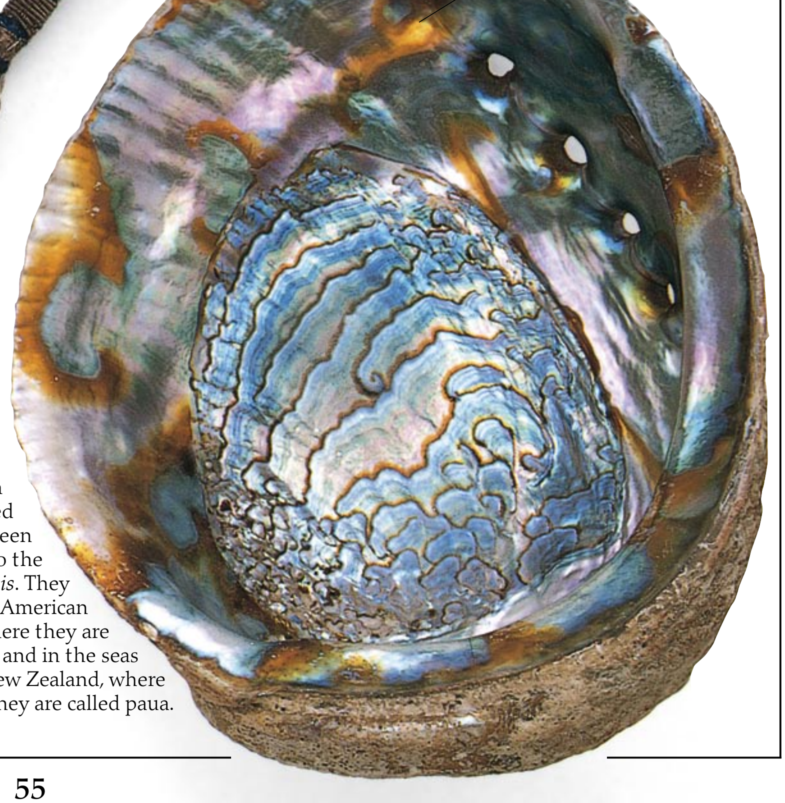
BUNCH OF PEARLS
Bombay, India, has been a center of pearl drilling for centuries. Some were sold as a "Bombay bunch." Each size was strung separately on silk, then combined with strings of other sizes suitable for a necklace, and finished off with tassels of silver wire.



CANNING JEWEL
Irregularly shaped pearls are called baroque pearls. There are four, including a magnificent one forming the body, in the Canning Triton jewel. It was probably made in south Germany in the late 16th century and is now in the Victoria and Albert Museum in London.

Baroque pearl

Pillbox with an abalone lid



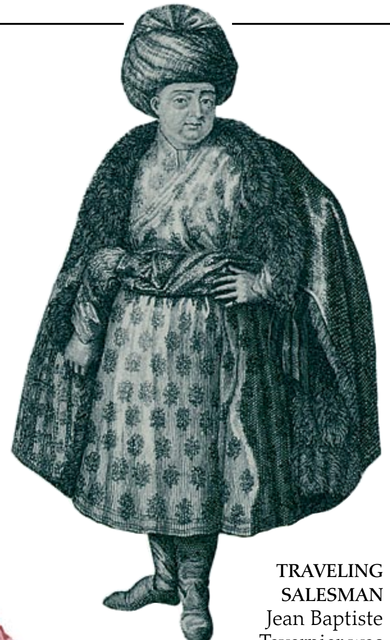
Iridescent nacre

SHELL SHINE
Shells with brightly colored blue and green nacre belong to the genus *Haliotis*. They are found in American waters, where they are called abalone, and in the seas around New Zealand, where they are called paua.

What is it worth?

THE MARKET VALUE OF GEMS plays a large part in persuading people to buy them. Fashions change, so that gems that were priceless in the 19th century may no longer be so, and vice versa. Farther back in time, lapis lazuli, turquoise, agates, and emerald were prized. From the fifth to the 14th century A.D. stones were not often cut because this was thought to destroy their magic. Since then, however, more and more stones have been cut to enhance their beauty, and they are traded to satisfy people's desire to display their style or wealth. Since medieval times diamond, ruby, pearl, emerald, and sapphire have been popular, while the popularity of species such as topaz, garnet, and aquamarine has gone up and down.

WHAT PRICE?
Gem values can vary widely, even within one species, according to color, clarity, and cut. This 57.26-carat sapphire is of such extraordinary size and fine color that it can only be valued if it changes hands.



TRAVELING SALESMAN
Jean Baptiste Tavernier was a remarkable Frenchman who lived in the 17th century. He traveled in Europe and Asia, buying and selling gems. His accounts of his travels are in such detail that they are used to research the origins of famous diamonds.

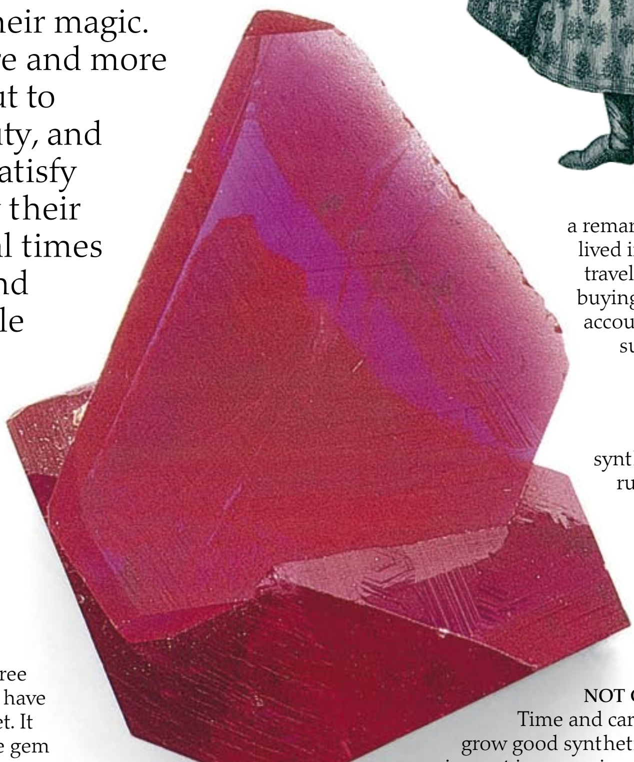
Carob pod

1-carat ruby

Carob seed

WEIGHT IN BEANS
The seeds of the carob tree are of remarkably constant weight and were used for centuries as a standard for comparing the weights of precious stones. Later, a standard weight similar to that of the carob seed was used, and it was called the carat. For some time the weight was slightly different in different trading centers, but early this century a metric standard of 0.007 oz (0.2 g) was agreed internationally.

PRICELESS
Painite is priceless. Only three crystals are known, and none have yet been on the open market. It was found in Myanmar by the gem dealer A.C.D. Pain and, when confirmed as a new species, was named after him.



Synthetic ruby crystals

Cut synthetic ruby

NOT CHEAP
Time and care are needed to grow good synthetic crystals, and the equipment is expensive. Stones cut from such crystals are therefore not cheap, but natural stones of similar color still cost 10 to 100 times more.

Chipped glass of a GTD

DOUBLED UP
A stone made of two materials glued or fused together is known as a doublet. Triplets have three layers – the central one being colored glass or cement. The most popular doublet is the garnet-topped doublet (GTD). The top is a thin piece of colorless garnet which is more durable than the glass base which provides the color. These cheaper stones are sometimes sold by disreputable traders as rubies, sapphires, or emeralds.

THEFT PREVENTION
This 1910 photograph shows Chinese sorters in the ruby mines of Mogok, Myanmar (pp. 36–37). The sorters were made to wear wire helmets to stop them from stealing rubies by hiding them in their mouths while they were sorting.

SHORT-LASTING
Red glass has long been used to imitate ruby, but its luster and shape soon deteriorate with age. In contrast, ruby, with its greater hardness and toughness, keeps these qualities far longer.

STONE SUBSTITUTES
Diamond (pp. 34–35) is the most frequently imitated stone in jewelry, as there are many people who cannot afford the real thing. The oldest imitations are glass and rock crystal, but in the 20th century synthetic garnets and then cubic zirconia became available. This selection of diamond simulants is arranged clockwise in order of increasing fire. The five stones GGG to synthetic rutile have more fire than diamond but cannot compare in their luster, hardness, or durability.

DIAMOND GRADING REPORT
05/09/90
3250919

THE FOLLOWING WERE, AT THE TIME OF THE EXAMINATION, THE CHARACTERISTICS OF THE DIAMOND DESCRIBED HEREIN BASED UPON 10X BINOCULAR MAGNIFICATION, DIAMONDLITE AND MASTER COLOR DIAMONDS, ULTRAVIOLET, MILLIMETER GAUGE, DIAMOND BALANCE, PROPORTIONSCOPE.

SHAPE AND CUT ... ROUND BRILLIANT
Measurements ... 7.72 – 7.75 X 4.72 MM.
Weight ... 1.75 CARATS
PROPORTIONS ...
Depth ... 61.0%
Table ... 65%
Girdle ... SLIGHTLY THICK TO THICK
Culet ... VERY SMALL
Finish ...
Polish ... VERY GOOD
Symmetry ... VERY GOOD
CLARITY GRADE ... SI1
COLOR GRADE ... G
Fluorescence ... NONE
COMMENTS:

RED SYMBOLS DENOTE INTERNAL CHARACTERISTICS. GREEN SYMBOLS DENOTE EXTERNAL CHARACTERISTICS. SYMBOLS INDICATE NATURE AND POSITION OF CHARACTERISTICS, NOT NECESSARILY THEIR SIZE. MINOR DETAILS OF FINISH NOT SHOWN. DIAGRAM MAY BE APPROXIMATE.

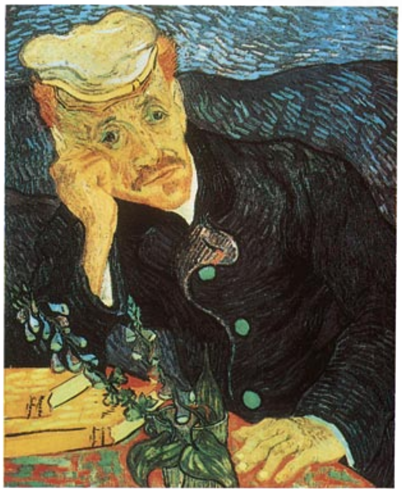
NOTICE: IMPORTANT LIMITATIONS ON REVERSE

Measurements are given in millimeters and the details of proportions, clarity, and color are listed

Clarity and color are graded on a scale. This diamond is graded SI_1 (small inclusion) for clarity and G (near colorless) for color

The positions of any inclusions are indicated on the outlines of the crown and pavilion



MILLION-DOLLAR MAN
The most valuable stones on the market in the past ten years have been diamonds, rubies, and emeralds, but even the most expensive diamond was only a fraction of the record price paid for Van Gogh's *Portrait of Dr. Gachet*. This was sold at Christie's, New York City, in May 1990 for $82.5 million.

FOUR Cs
Two diamonds that look alike at first can have very different values. Four characteristics that determine their value are known as the four Cs: cut, weight in carats, color, and clarity. In the 1930s, the Gemological Institute of America established its own system of grading and issued certificates for individual diamonds containing information about the four Cs. Different systems were introduced in Europe, but in 1975 the grading procedure started to be standardized.

MADE TO MATCH
Opal (pp. 40–41) is imitated in several ways. The flamboyant Slocum stone is made of glass and is much cheaper than true opal. Gilson opal is grown in the laboratory over many months and is intermediate in value. True opal is graded according to body color and the play of colors, with black opal being the rarest and most expensive.

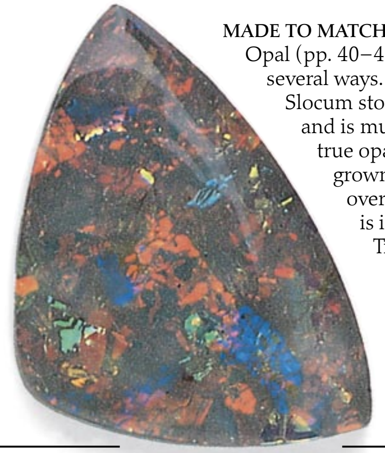
Gilson opal



Slocum stone

Making them sparkle

SOME ROUGH CRYSTALS are beautifully shaped and have breathtaking luster and color, but most are worn down or have other surface imperfections. A skilled stonecutter and polisher, called a lapidary, can turn these stones into objects of beauty and value by using their individual qualities in the right way. Beads and cabochons are the oldest cuts for such materials as lapis lazuli and turquoise (p. 50), and carnelian and agate (p. 33). Brilliant-cut diamonds are known from the 17th century, and brilliant is the most popular cut for diamonds today.

BRILLIANT-CUT RUTILE
In 1919 Marcel Tolkowsky set down the precise angles and proportions of a brilliant cut to give the best combination of sparkle, brilliance, and fire.

ROSE-CUT SMOKY QUARTZ
The rose cut dates from the 14th century. Most stones have a flat base and a shallow or deep dome-shaped top covered in triangular facets.

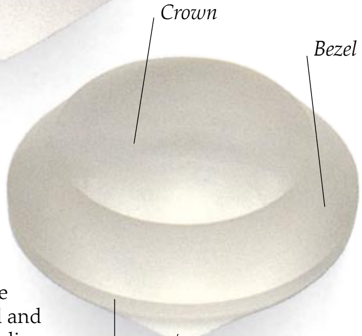
TABLE-CUT AMETHYST
The table cut is derived from the diamond octahedron by sawing off the top above what becomes a square or rectangular girdle.

STEP-CUT QUARTZ
The step cut has many rectangular facets. It is particularly suitable for strongly colored gems, such as emerald and tourmaline.

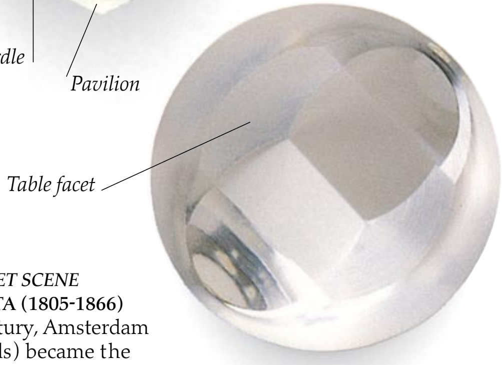
Cutting a brilliant

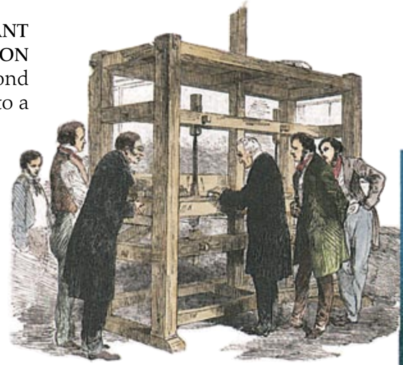
A lapidary first studies a rough stone with a powerful lens called a loupe. This shows the direction of grain and the flaws. The stone is marked to show where it should be sawed and the facets are then ground.

1 **ROUGH CHOICE**
A rough crystal is chosen for cutting.



2 **SAWED IN TWO**
The crystal is sawed to remove the top pyramid and rounded by grinding against another diamond, called bruting. (The cutting sequence is shown here with models.)





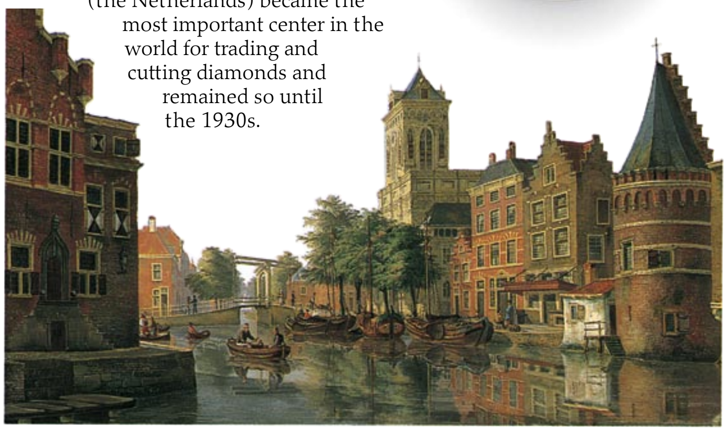
BRILLIANT TRANSFORMATION
The Koh-i-noor diamond (p. 35) was recut into a brilliant in 1852. Here the Duke of Wellington makes the first facet, watched by Mr. Voorsanger, the cutter from Amsterdam.

The Koh-i-noor cut as a brilliant

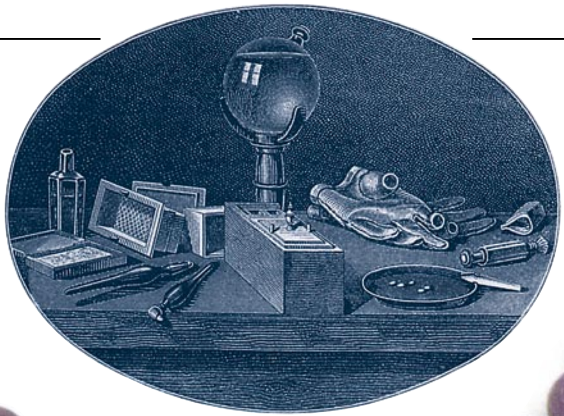
3 **FACETING BEGINS** *left*
The stone is mounted on a stick called a dop, and the first facet – the flat table – is ground on a cast-iron wheel, called a scaife, followed by more facets.

4 **FACETED** *left*
Four "bezel" facets are ground between the table and the girdle. The stone is turned over and four facets ground on the pavilion. Four more facets are ground on the crown and on the pavilion, and the "culet" facet on the base.

5 **FINISHED OFF** *right*
The stone is finished by the brillianteerer, who adds 24 facets above and 16 below the girdle. The standard brilliant has 57 facets or 58 with a culet.



AMSTERDAM STREET SCENE
BY PETRUS BERETTA (1805-1866)
In the 17th century, Amsterdam (the Netherlands) became the most important center in the world for trading and cutting diamonds and remained so until the 1930s.



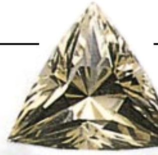
Diamond cutter's table of the 1870s

Agate

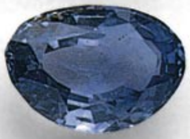
Amethyst

OLD FASHION
Beads can be made out of relatively soft materials and are among the oldest forms of fashioned gems. They are made today using automatic machines.

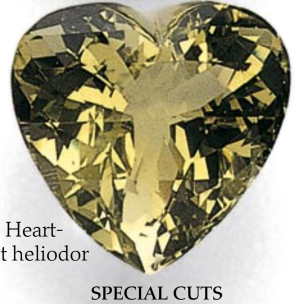
CUTTING IT FINE
These craftsmen from Perth, Australia, are cutting diamonds from the Argyle mine (p. 25). Diamond-cutting tools remained virtually unchanged from the 15th century until the development of automatic machines in the 1970s and, later, lasers.



Triangular-cut citrine

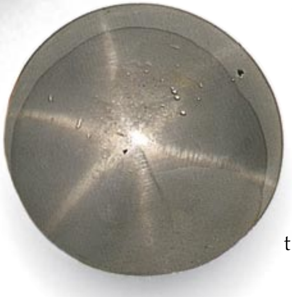


Irregular-cut sapphire

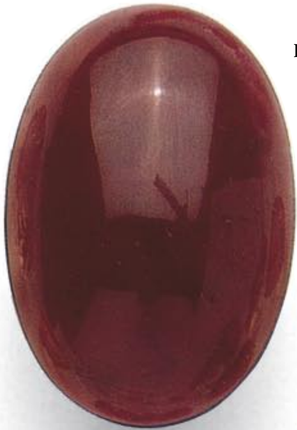


Heart-cut heliodor

SPECIAL CUTS
If a stone is very rare, a special cut may be developed to keep as much weight as possible. Or stones may be given unusual cuts for special occasions.



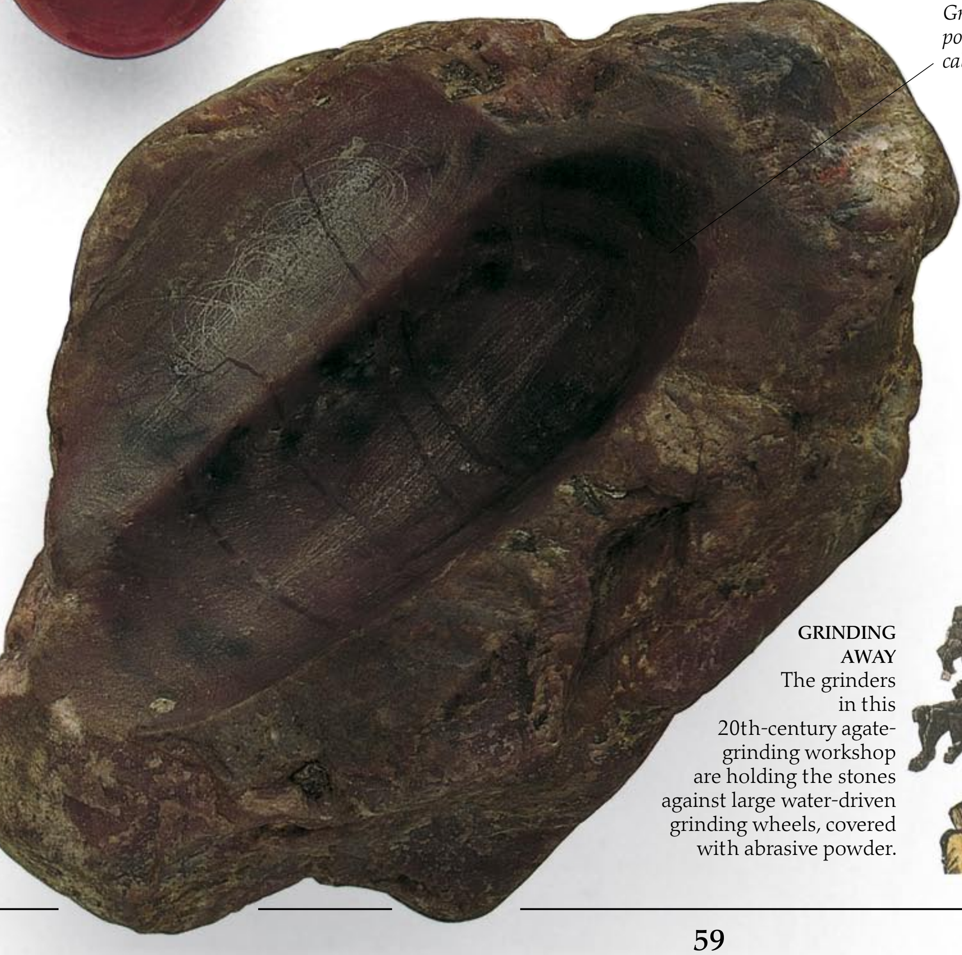
LIGHT DISPLAY
Star sapphires and rubies (p. 37) must be cut as cabochons if the tiny needles of rutile inside are to reflect the light and display the star.



HARDHEADED
Hard-wearing opaque materials such as this garnet are often cut into rounds or ovals with plain, curved surfaces. These are called cabochons – a French word derived from the Latin *cabo*, meaning a head.

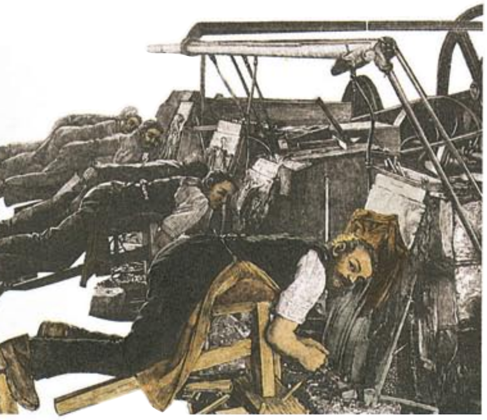
Cabochons of quartz, cut to display the cat's-eye effect and set in a brooch

OVER AND OVER
Rocks and minerals can be polished by tumbling them in a drum with water and grit. The kind of grit depends on the material to be polished; it ranges from coarse grits to start with, to fine grits for finishing.



Groove caused by polishing garnet cabochons

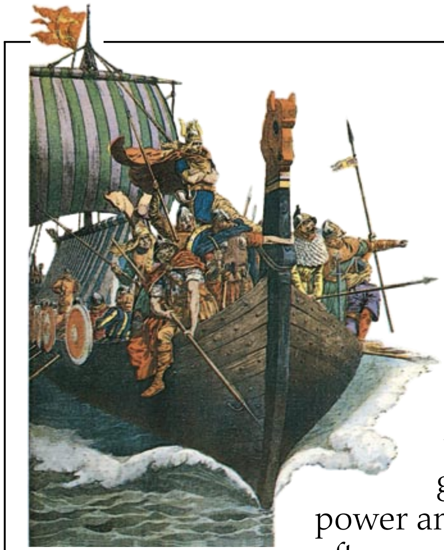
INDIAN POLISH
This massive corundum was used in India in the 19th century for fashioning and polishing garnets. Continual use has caused tiny chips to split off, eventually leaving grooves.



GRINDING AWAY
The grinders in this 20th-century agate-grinding workshop are holding the stones against large water-driven grinding wheels, covered with abrasive powder.

Lore and legends

Superstition, myth, and romance have been attached to crystals since ancient times. In Persian mythology the world is said to stand on a giant sapphire, the reflection of which colors the skies blue. Emeralds were once thought to blind snakes, and wondrous medicinal properties have been given to diamonds. Rubies were symbols of power and romance in the Middle Ages, and ladies often presented jewels to their knights as love tokens. Many specific stones are said to have been put under a terrible curse and stories are told of how some, such as the Hope diamond, bring disaster to their owners.



CRYSTAL COMPASS
Some sources say that the Vikings navigated with transparent cordierite crystals. When held up to sunlight and rotated, cordierite darkens and changes color. Using this property, the Vikings would have been able to work out compass directions.

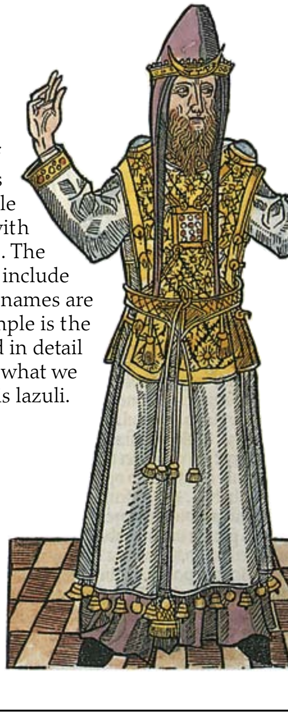
BRAINY BIRDS
The mystery of how a bird migrates may have been solved. It is thought that a tiny magnetic crystal in its brain detects the earth's magnetic field.

Iron filings attracted to magnetite fan out to follow magnetic lines of force

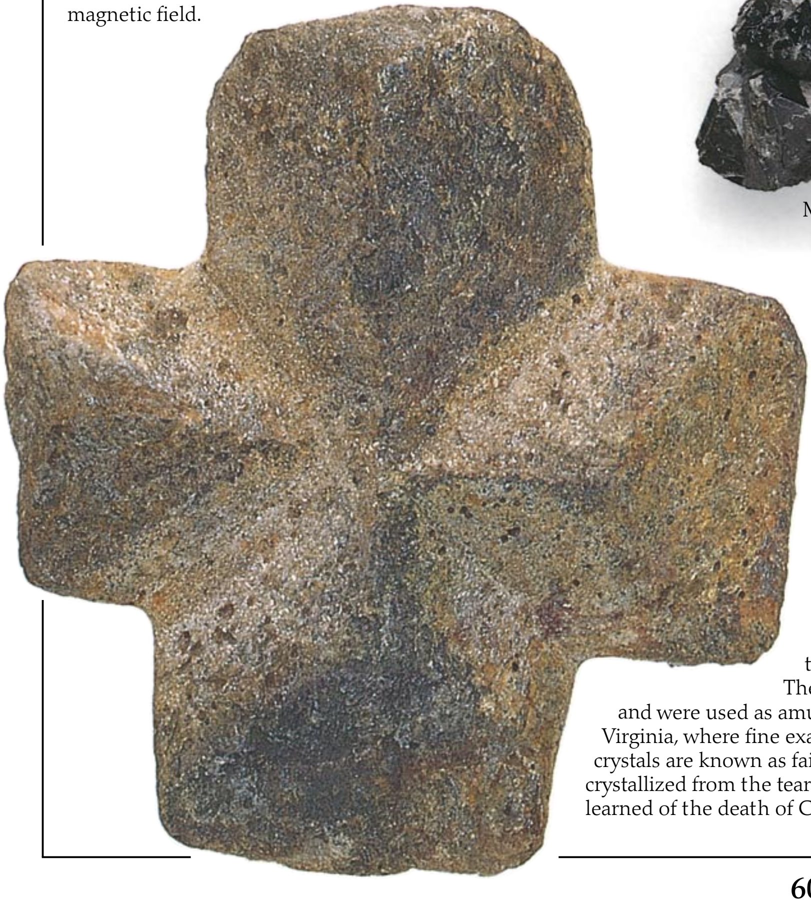
POWER TO REPEL
Some pieces of magnetite, a naturally occurring iron oxide, are magnetic. They are known as lodestones, and people in ancient times believed they had special powers. For example, it is said that Alexander the Great, a famous general of the third century B.C., gave lodestones to his soldiers to repel evil spirits.

Magnetite crystals

SOBERING INFLUENCE
Amethyst was supposed to have many useful powers in the 15th century, but its traditional virtue was its ability to cure drunkenness. One way in which it may have gained this reputation is that drinking vessels were sometimes made of amethyst. In these, water would look like red wine, but could be drunk with no intoxicating effect!



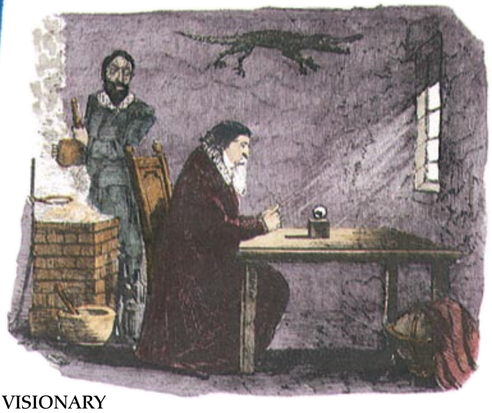
HOLY ROWS
The original breastplate of the High Priest of Israel is described in the Bible (Exodus 28: 15–30) as set with four rows of three stones. The stones are all named and include familiar species, but some names are misleading. An example is the sapphire. This is described in detail elsewhere and is evidently what we now know as lapis lazuli.



STONE TEARS
Crystals of staurolite sometimes twin at right angles to form crosses. These used to be called *lapis crucifer* and were used as amulets at baptisms. In Patrick County, Virginia, where fine examples have been found, these twin crystals are known as fairy stones. The legend is that they crystallized from the tears of fairies, who cried when they learned of the death of Christ.

Crystal gazing

Crystal balls have been used for telling the future since Greek and Roman times. The fortuneteller looks at the polished surface of the ball intently until he or she can no longer focus on the ball but sees instead a curtain of mist. This enables the gazer to see "visions" in the ball, imagined in response to questions asked by the person whose fortune is being told.



VISIONARY
John Dee was a charlatan of the 16th century but a favorite of Queen Elizabeth I of England. He conducted many crystal gazings in which a colleague, Kelley, interpreted "visions" in the crystal.

FOR THE FUTURE
Quartz (pp. 30–33) is the most popular material for crystal balls, but other materials which have a shiny surface, such as mirrors, polished steel, and even the surface of water, have been known to produce a satisfactory effect.

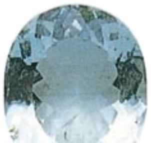
EASTERN SEER
Crystal balls have been found from cultures in the Far East, the Americas, and Europe. This one comes from China.

Birthstones

The dedicating of a special stone to each month of the year was first suggested in the 1st century A.D., and was linked to the twelve stones in the breastplate of the High Priest of Israel. The custom of wearing such stones became popular in the 18th century. It started in Poland and then spread throughout Europe and the rest of the world.

January – Garnet

February – Amethyst



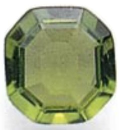
March – Aquamarine

April – Diamond

May – Emerald

June – Pearl

July – Ruby



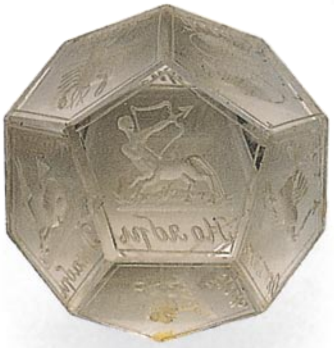
August – Peridot

September – Sapphire

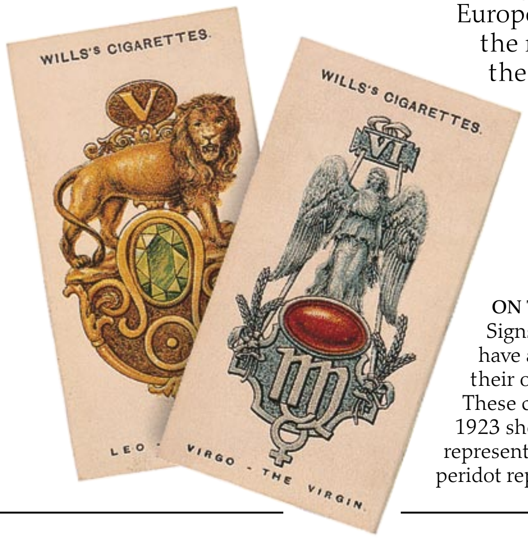
October – Opal

November – Topaz

December – Turquoise



Rock crystal engraved with the twelve signs of the zodiac



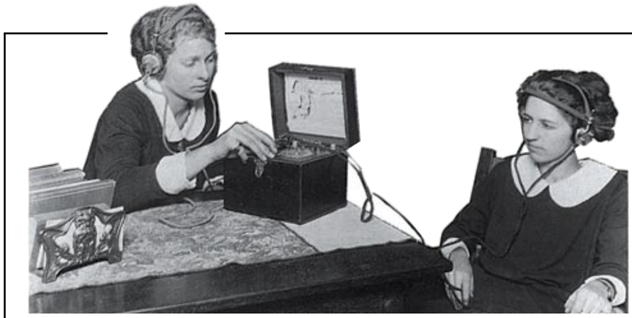
WILLS'S CIGARETTES.
V
LEO
WILLS'S CIGARETTES.
VI
VIRGO - THE VIRGIN.

ON THE CARDS
Signs of the zodiac have also been given their own gemstones. These cigarette cards of 1923 show carnelian representing Virgo and peridot representing Leo.

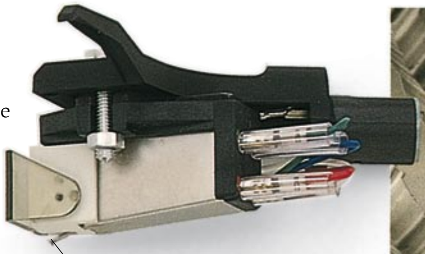
CHANGING MONTHS
The gem species which represent each month have varied considerably throughout history. The Roman, Arabian, Jewish, and Russian cultures all favored different combinations. The group shown here is the most popular today.

Crystals at home

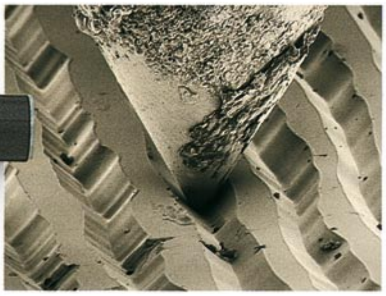
MANY EVERYDAY OBJECTS in the home are crystalline. There are ice crystals in the freezer, salt and sugar crystals in the food cupboard and in food itself, crystals of vitamin C and aspirin in the medicine cabinet, tartrate crystals in the wine bottle, and silicon crystal chips in the refrigerator and washing machine. The TV, telephone, radio, and camera work because of crystals, the house is built of materials which are mostly crystalline, and outside, bikes and cars stand slowly rusting – crystallizing!



BY A WHISKER
"Hello. This is New York. Here is the news." This might be what these women are listening to using a crystal set. In this early form of radio, operators moved a thin copper wire, sometimes known as a cat's whisker, against a galena crystal to pick up radio waves. Crystal sets became popular in the 1920s when public broadcasting began.



FOR THE RECORD
In some record players, there are two crystals. The stylus is made of hard-wearing diamond or corundum, and a piezoelectric crystal (p. 31) in the cartridge converts vibrations received from the record into an electrical charge.

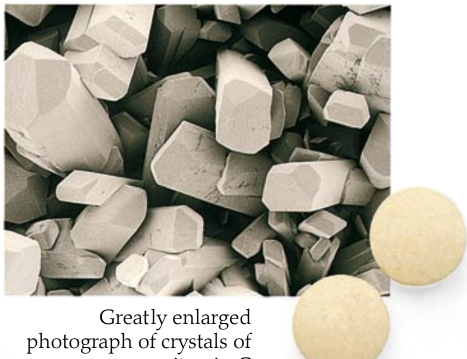


Enlarged photograph of a diamond stylus traveling through the groove on a stereo record

SPOONFUL OF SUGAR
Over 100 million tons of sugar are crystallized every year in refineries. Sugar is extracted as a liquid solution from raw sugar cane or beet, then converted into sugar crystals. The silver spoon holding these sugar crystals is itself a mass of silver crystals.

Liquid crystal display

CRYSTAL DISPLAY
The displays in many calculators are liquid crystal displays (LCDs). Liquid crystals are not truly crystalline. They flow like a liquid but have molecules arranged like those of crystals and some properties of crystals. Power rearranges the molecules so that they reflect or absorb light and show dark or light.



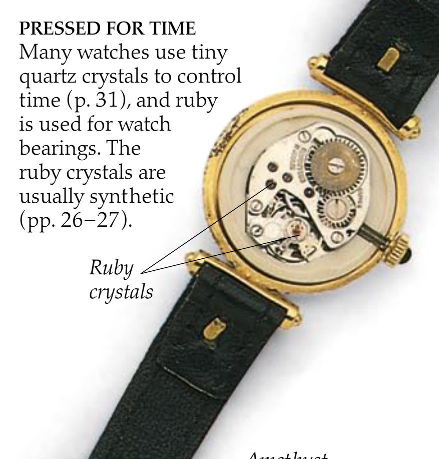
Greatly enlarged photograph of crystals of vitamin C

VITAL INTAKE
These tablets contain crystals of ascorbic acid, or vitamin C. Ascorbic acid is a white crystalline substance present in plants, especially citrus fruits, tomatoes, and green vegetables. Vitamins are essential to us in small quantities. Most cannot be produced by the body, and therefore have to be taken in through food or tablets.

Collecting

Crystal collecting can be enjoyed without spending too much money. Crystals can be collected in the field, bought, or exchanged with friends and dealers. They are usually fragile and should be carefully stored. Those found in the field should be kept with details of where they were found and, if possible, their host rock.

PRECIOUS STONES
Many people own jewelry made with precious or semiprecious stones. This silver brooch contains diamonds, a blue sapphire, and a pearl.



PRESSED FOR TIME
Many watches use tiny quartz crystals to control time (p. 31), and ruby is used for watch bearings. The ruby crystals are usually synthetic (pp. 26–27).

Ruby crystals

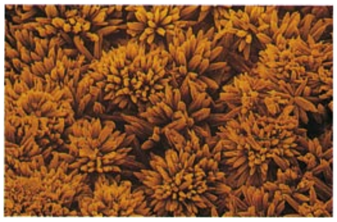


Photo enlargement of needle-like crystals in kettle "fur"

KETTLE FUR
Crystals can be found in your kettle. Even after purification processes there are still some harmless minerals dissolved in tap water. These crystallize and coat the inside of your kettle when the water is boiled.

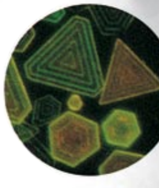

Photo enlargement of silver nitrate crystals on a photographic film

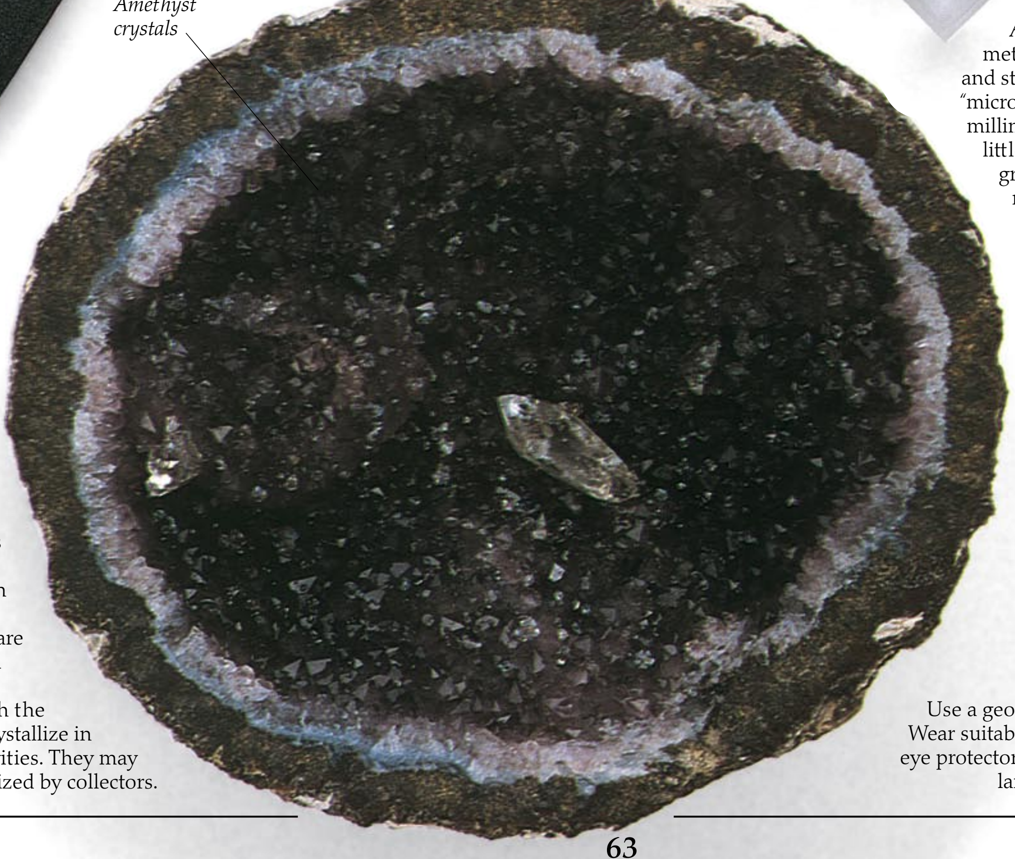
ON FILM
When a photograph is taken, an image is recorded on light-sensitive material by the action of light. Most film uses light-sensitive crystals of silver salts. The photographic industry is one of the largest users of silver.

Hand lens for studying the major features of crystals

Wulfenite crystal

IN MINIATURE
A popular method of collecting and storing crystals is as "micromount" specimens a few millimeters in size. They take up little space, and fine crystal groups of rare and unusual minerals can be collected.



Amethyst crystals

CAVITY FILLERS
Crystal-lined geodes are often found within basaltic lava flows. They are formed from fluids which filter through the rocks and crystallize in available cavities. They may be highly prized by collectors.

FIELDWORK
Use a geological hammer to collect in the field. Wear suitable clothing and boots, a hard hat, and eye protector. Ask permission to collect on private land and always observe the local laws.

Did you know?

AMAZING FACTS

In ancient times, the Persians thought the Earth rested on a giant sapphire and that the blue of the heavens was its reflection. Others thought the sky was a sapphire in which the Earth was set.

Sapphire and diamond pendant

Sapphire-blue is a color associated with the qualities of harmony, trust, and loyalty. This is the reason why women in many countries choose sapphires as the stones in their engagement rings.

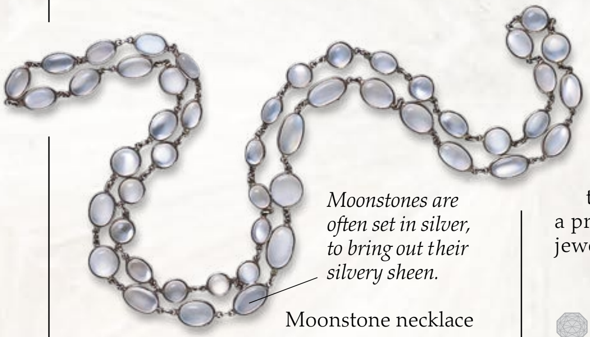
The name "garnet" comes from the Latin for pomegranate, a fruit which has bright red, garnetlike seeds. In fact, the color of garnets varies from violet-red to the deepest burgundy.

Pomegranate

Diamonds are sometimes found under the sea. People trawl for diamonds off the coast of Namibia in southern Africa. The latest techniques involve large offshore ships pumping gravel containing diamonds up to the surface.

Since diamond was discovered in kimberlite rock, it has been extracted on a massive scale. Over 25 tons of rock have to be blasted for every finished carat—0.007 oz (0.2 g)—of diamond mined.

In medieval times, people who could afford it wore a diamond jewel to protect them from the plague. The Ancient Greeks thought that diamonds could protect people from poisons.



Moonstones are often set in silver, to bring out their silvery sheen.

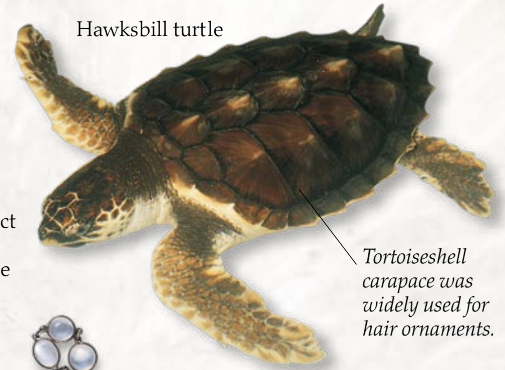
Moonstone necklace

People once thought that a moonstone's opalescent luster waxed and waned just like the Moon, so moonstones have always been worn by worshipers of the Moon.

Topaz crystals can be over 3 ft (1 m) long and weigh hundreds of pounds. The name "topaz" is thought to come from the Sanskrit word *tapas*, which means "fire."

The Ancient Greeks thought that amber was the hardened rays of a sunset and it was considered sacred to the Sun god Apollo. Amber can produce an electric charge when rubbed. In fact, the word "electricity" comes from the Greek word for amber, *elektron*.

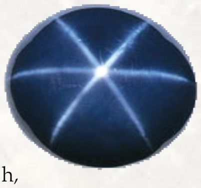
Hawksbill turtle



Tortoiseshell carapace was widely used for hair ornaments.

Tortoiseshell doesn't come from a tortoise at all, but from a turtle. It is made from the shell of the rare Hawksbill turtle, which is now a protected species. Most "tortoiseshell" in jewelry today is made of plastic.

Six-rayed star sapphires were once thought to provide the best protection from evil. The three crossing arms of the star were meant to represent faith, hope, and destiny.



Star sapphire

To the Egyptians, the intense blue of lapiz lazuli meant that it was a heavenly stone. They often used it on statues of their gods and in burial masks, to protect them in the next life.

The Arabians thought that pearls were the tears of gods. Although cultivating pearls (making them grow by putting irritants into oysters) is much faster than waiting for natural pearls to form, it can still take a very long time—up to 4 years.

Diamond dredging boats

QUESTIONS AND ANSWERS

Q **How long have people been mining for gemstones?**

A Jewelry has been found in burial sites dating back thousands of years. Ancient jewelry is rare, but some Ancient Egyptian pieces have survived. These are often made of gold set with gems such as turquoise, lapis lazuli, and carnelian.

Q **What are potato stones?**

A Potato stone is a name given to a geode, a hollow ball of rock encrusted inside with amethyst or other crystals. The crystals form when silica-rich liquids seep into gas bubbles in lava as it cools to form volcanic rock. Also known as thunder eggs, geodes are highly prized.

Potato stones

Q **Why are gemstones so precious?**

A Gemstones are valuable because of their natural beauty, their durability, their rarity, and the way in which they are cut and polished. There are 3,000 different kinds of mineral, but only about 100 could be classed as gemstones, making them very rare.

Q **Where do diamonds come from?**

A Diamond forms at extremely high temperatures and pressure 50 miles (80 km) or more below the ground in the Earth's mantle. When diamonds were first discovered, 2,000 years ago, they were mainly found in river gravel. These days, most diamond is mined from kimberlite rock. Australia is the main producer today, but diamonds are also mined in Africa, Russia, Brazil, and the US.

Q **What are seed pearls ?**

A Pearls vary in size, the smallest of all being seed pearls. Pearls are not weighed in carats like other gemstones, but in grains. One grain = 0.002 oz (0.05 g). Seed pearls weigh less than 0.25 of a grain.

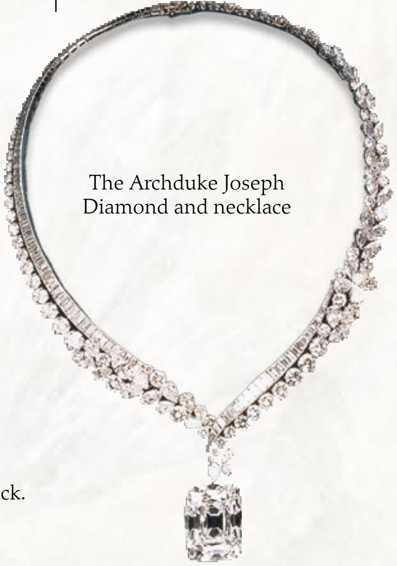
Scarab beetle good-luck charm, found in Tutankhamun's tomb

Q **Why were children often given coral jewelry in the past?**

A Coral was thought to protect the person wearing it from evil. For this reason, children were often given coral necklaces and bracelets to keep them healthy and safe from harm.

Q **Why are emeralds green?**

A The characteristic green color of emeralds come from tiny amounts of chromium and vanadium.



The Archduke Joseph Diamond and necklace

Q **Why are gemstones cut and polished?**

A Cutting and polishing gemstones transforms them into jewels. It maximizes the amount of light they reflect so that they sparkle and shine.

Q **Why are organic gems often carved rather than cut into facets?**

A Organic gems, such as coral, ivory, amber, jet, and pearl are softer than mineral gems and are often opaque. For this reason, they are often carved and polished. Light cannot shine through them, so it is pointless to cut them into facets to increase their brilliance.

Q **What is the connection between rubies and emery boards?**

A Rubies are one of the most expensive gems. Ruby is a variety of the mineral corundum, which is second in hardness to diamond. Emery is an impure form of corundum and has been used as an abrasive for thousands of years.

Cut ruby

Q **Which famous ruby isn't really a ruby at all?**

A Many crown jewels around the world contain massive red gemstones called spinels, which people mistook for rubies. The huge Black Prince's Ruby in the British Imperial State Crown is in fact a spinel, given to the Black Prince in 1367 by the king of Spain as a token of his appreciation.

Record Breakers

MOST VALUABLE GEMSTONE:
Diamonds are the most precious gems, famed for their fiery beauty, as well as for being the hardest mineral on Earth.

BIGGEST DIAMOND:
The largest single rough diamond ever mined was the Cullinan diamond, found in 1905 in South Africa. It weighed 3,106 carats and was cut into 9 large and 96 smaller stones.

CUTTING MARATHON:
It took three polishers, working 14 hours a day, eight months to cut and polish the Cullinan 1 diamond. The stone is now set in the British Imperial Scepter.

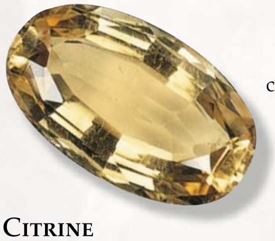
PRICELESS GEM:
Only three crystals of painite are known, and none of them has ever been sold, making them priceless.

BIGGEST BERYL CRYSTAL:
A beryl crystal found in Madagascar weighed 39 tons (36 metric tons) and was 60 ft (18 m) long.

Identifying gemstones

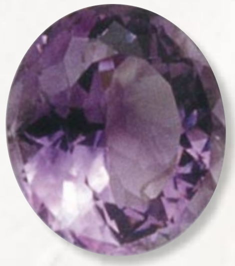
Emerald lizard

To THE UNTUTORED EYE, many gemstones look alike. They are often similar in color and are cut in much the same way. Here is a guide to the color and characteristics of some of the most popular gemstones, both mineral and organic.



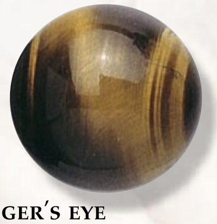
Mixed-cut citrine with the orange tinge often seen in this gem

CITRINE
Citrine is a yellow or golden form of quartz. Natural citrine (its name comes from the word "citrus") is pale yellow, but it is extremely rare.



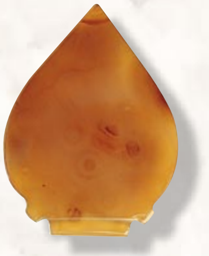
Oval mixed-cut amethyst with a typical purplish violet color

AMETHYST
Amethysts are purple, lilac, or mauve quartz crystals. They often have distinctive internal markings and a blue or reddish tinge when seen from different angles.



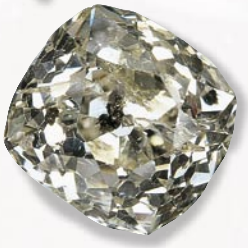
Tiger's eye, cut and polished to show up its stripes

TIGER'S EYE
Tiger's eye is a variety of chalcedony, a type of quartz composed of tiny fibers. It has a waxy appearance and is black with yellow and golden-brown stripes.



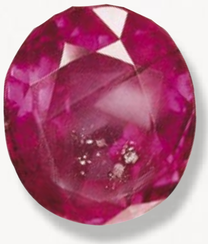
Typical reddish orange polished stone from India

CARNELIAN
Also called cornelian, this is a translucent, reddish-orange or brown form of chalcedony.



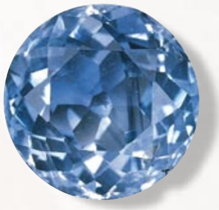
Colorless, brilliant-cut diamond with black inclusions

DIAMOND
Made of pure carbon, diamond is exceptionally hard and shines brightly. It occurs in many colors, but the most popular variety is pure and colorless.



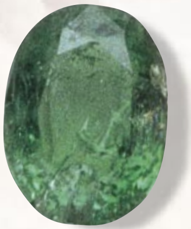
Cushion mixed-cut ruby in bright red

RUBY
One of the most expensive gems, the classic ruby is a rich red, but it can vary in color from pink to brown. Rubies are second in hardness only to diamonds.



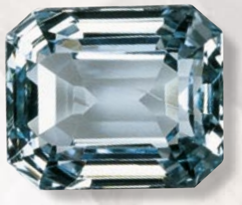
Pale blue Sri Lankan sapphire

SAPPHIRE
The most valuable sapphires are a clear shade of deep blue, but they can also be yellow, green, pink, or colorless. Like ruby, sapphire is a type of corundum.



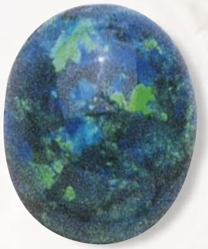
Bluish-green emerald with many tiny fissures and internal markings

EMERALD
A variety of beryl, emeralds are a rich green. Only the finest gems are transparent and flawless. Most emeralds have flaws known as a *jardin*, the French for "garden."



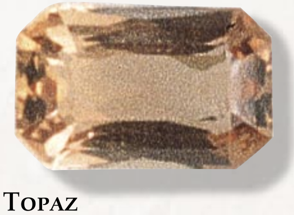
Octagonal step-cut aquamarine with a slight greenish tinge

AQUAMARINE
Another variety of beryl, aquamarine ranges in color from pale sea-green to dark blue. It can appear to change color when viewed from different angles.



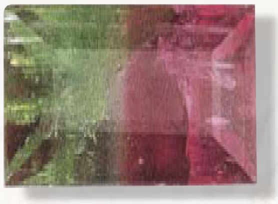
An opal displaying flashes of green and blue

OPAL
Opal is known for its iridescence and flashes of color. Iridescent opal with a dark background is called black opal. "Potch opal" is opaque, without any iridescence.



Salmon-pink colored topaz

TOPAZ
Topaz occurs in several different colors, ranging from deep golden yellow (known as sherry topaz) and pink to blue and green. Natural pink stones are extremely rare.



Watermelon tourmaline

TOURMALINE
Tourmalines come in a range of colors, but they all have the same crystal structure. Watermelon tourmaline is so called because of its pink and green coloring.

Pyrope (garnet) cut as an oval

Garnet

There are several different gemstones in the garnet group. The most popular for jewelry are the pyrope, which is blood-red, and the deep red almandine.

Octagonal mixed-cut peridot

Peridot

Peridot is an olive or bottle-green color with a distinctive waxy luster. It has strong double refraction, which means you can often see a doubling of the back facets.

A gray moonstone

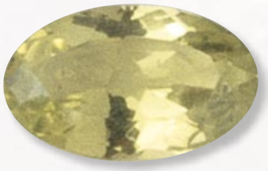
Moonstone

The moonstone derives its name from its blue-white sheen, like moonshine. Some varieties are gray, yellow, pink, or green.

Octagonal mixed-cut with a vitreous luster

Spinel

The most popular spinel is ruby-red, but it also occurs in blue and yellow. Until the 19th century, red spinels were known as Balas rubies, perhaps after their source.



Cut yellow chrysoberyl

Chrysoberyl

Chrysoberyl is renowned for its golden color. One variety, called alexandrite, appears to change color from green to light red when seen in artificial light.

Colorless zircon produced by heating a reddish-brown stone

Zircon

Pure zircon is colorless and resembles diamond, but it is more likely to be golden brown. Many zircons are heat-treated to produce blue or colorless gemstones.

Translucent jadeite with black inclusions

Jade

Two different minerals, jadeite and nephrite, are recognized as jade. The finest quality jadeite is emerald green. Nephrite varies in color from cream to olive green.

Polished rock speckled with pyrite

Lapis lazuli

Prized for its intense dark blue, lapis lazuli is a rock made up of several minerals. Specks or streaks of pale pyrite and calcite are often visible against the blue.

Stone cut and polished as a cabochon

Turquoise

Turquoise is valued for its intense color, which varies from blue–green to bright blue. Opaque, it is usually cut and polished into rounded beads or cabochons.

ORGANIC GEMSTONES

Unlike most other gemstones, which are mineral in origin, organic gems are derived from plants and animals. Amber, jet, coral, pearl, ivory, and shell are all organics. These materials are not stones and they are not as hard and durable as mineral gems. Instead of being cut into facets like most other gemstones, they are usually polished or carved.

Carved jet with a finely wrought rose at the center

Jet

Jet is a fine-grained rock formed from fossilized wood. Black or very dark brown, it is opaque with a velvety luster. Once popular for mourning jewelry, it is often faceted and polished to a high shine.

Transparent golden brown beads that have been faceted

Amber necklace

Amber

Amber is formed from the hardened resin of trees. Transparent or translucent, it is usually a golden orange color, but it can also be a rich dark red, and occasionally contains insects and plants.

Intricate red coral carving showing a monkey climbing a tree

Coral

Coral is made of the remains of coral polyps. It can be pink, red, white, or blue. Naturally dull, it shines when polished.

A roughly spherical pearl suitable to be used as a bead

Pearl

Pearls are formed in shellfish and have a characteristic iridescent sheen. They vary in color from white and cream with a hint of pink to brown, or even black.

Find out more

THE BEST WAY TO find out more about crystals and gemstones is to visit museums. Natural history and geological museums usually have extensive rock and mineral displays and are an invaluable source of information on how crystals are formed and what they look like in their natural state. Many of them also have good gemstone collections. There are many different places where you can see how precious gems have been used in jewelry. Here are some suggestions for interesting places to visit, as well as a list of useful websites that will provide you with plenty more information.

CRYSTALS AND GEMSTONES
In most natural history and geological museums, such as the Earth Galleries at the Natural History Museum in London, England, there are wonderful displays of cut gemstones and famous jewels, specially lit to show them to their best effect. There are also excellent examples of crystals and gemstones in their natural state, often still embedded in their matrix (host) rock.

WHERE GEMSTONES ARE FOUND
Some mineral gemstones, such as quartz and garnet, are found all over the world. Others, such as diamonds, are far more rare. Where gemstones are found depends on particular geological conditions. This map shows the main locations around the world of 12 of the most popular and highly prized gems. If you visit any of these areas, you may be able to visit mines or see samples of the gemstones in local galleries, museums, and shops.

GEM COLLECTIONS
There are often private collections of gemstones on display in museums. You could start a gem collection of your own. Look for specimens on beaches, riverbanks, and hillsides. Clean your finds with water and let them dry, then arrange them in empty matchboxes or small cardboard trays. Try taking them to your local museum for help in identifying them.

Cut gemstones that form part of the Mathews collection in London, England

USEFUL WEB SITES

- Learn about U.S. geography through games and pictures, as well as great hands-on activities you can try at home: **www.usgs.gov/education/**
- See pictures of more than 1,000 different types of minerals: **webmineral.com/specimens.shtml**
- You can see great gems from the Smithsonian Gem and Mineral Collection at: **www.gimizu.de/sgmcol/**
- Games and activities about minerals and mining are a great source of information: **www.womeninmining.org/**

Places to visit

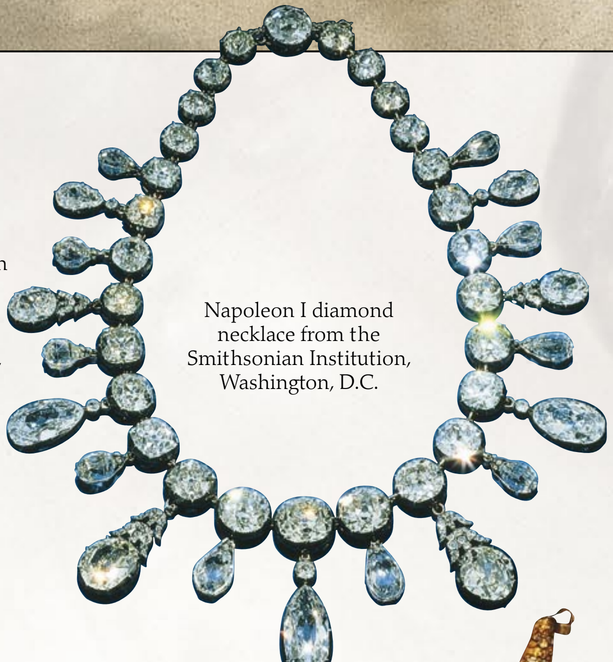
THE NATIONAL MUSEUM OF NATURAL HISTORY AT THE SMITHSONIAN INSTITUTION
10th Street and Constitution Avenue, NW,
Washington, D.C. 20560
This impressive collection is home to some famous gems, including the Hope Diamond, the largest diamond in the world.

HENRY FORD MUSEUM
20900 Oakwood Boulevard
Dearborn, MI 48124-4088
The museum houses a large collection of American-made jewelry up to 300 years old.

CARNEGIE MUSEUM OF NATURAL HISTORY
4400 Forbes Avenue
Pittsburgh, PA 15213
More than 350 minerals are on display in the Hillman Hall of Minerals and Gems.

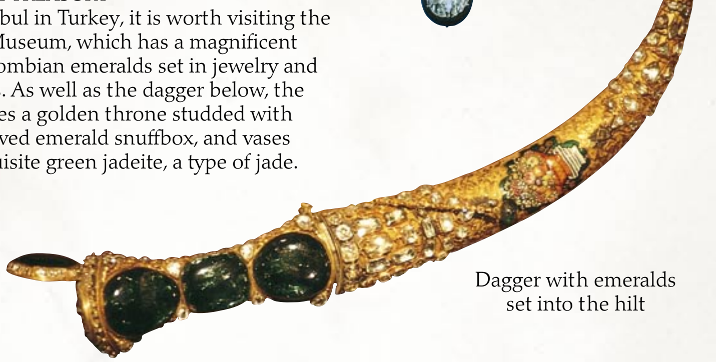
THE FIELD MUSEUM
1400 S. Lake Shore Drive
Chicago, IL 60605-249
Discover the basics about minerals and gems.

JEWELS AND JEWELRY
A museum of decorative arts is a good place to see how gemstones have been set in jewelry over the ages. In addition to historic pieces, modern jewelry in styles such as Art Deco are well worth looking at. To see examples of early jewelry, try visiting the Ancient Egyptian section of a museum. If you travel abroad, visit local craft museums to see samples of ethnic jewelry.



Napoleon I diamond necklace from the Smithsonian Institution, Washington, D.C.

TOPKAPI PALACE TREASURY
If you go to Istanbul in Turkey, it is worth visiting the Topkapi Palace Museum, which has a magnificent collection of Colombian emeralds set in jewelry and other accessories. As well as the dagger below, the collection includes a golden throne studded with tourmaline, a carved emerald snuffbox, and vases carved from exquisite green jadeite, a type of jade.



Dagger with emeralds set into the hilt

CROWN JEWELS
Impressive examples of famous gemstones set in gold and silver are on display in the Crown Jewels of France, Britain, and Austria. At the Louvre in Paris, France, you can see the coronation crowns of Napoleon and Louis XV, as well as other magnificent crowns, scepters, and swords, some dating back as far as the Middle Ages. Also on view is the Regent, one of the purest diamonds in the world, which was worn by Louis XV at his coronation in 1722. The British Crown Jewels are on display at the Tower of London and include many jewels that are still used in state ceremonies today, such as St. Edward's Crown, the crown of England, which is only used for coronations, and the Imperial State Crown, which contains the famous Black Prince's Ruby.

Charlemagne (742–814), king of the Franks

Golden scepter set with gemstones, made for Charles V in 1380

Gold set with precious jewels

Crown of Empress Eugénie on display at the Louvre

The Tower of London Education Center in London, where schoolchildren can try on replicas of the crown jewels and royal cloaks, as well as armor.

Glossary

ALLOCHROMATIC A term meaning "other-colored." It describes gems that are naturally colorless but are colored by tiny amounts of impurities.

ALLUVIAL DEPOSITS Weathered fragments of rock that have been carried along in rivers and streams and deposited elsewhere.

AMORPHOUS Without a regular internal atomic structure or external shape.

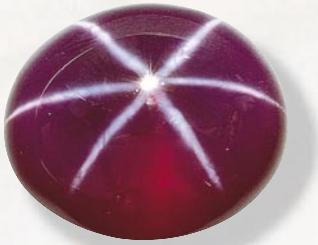
ASTERISM The star effect seen in some gemstones, such as rubies and sapphires, when they are cut into cabochons.

BIREFRINGENCE (DR) Double refraction, a property of some crystals in which light passing through them is split into two rays.

Brilliant cut diamond

BRILLIANT CUT The most popular cut for diamonds and many other stones. The standard brilliant has 57 facets, or 58 if the gem is cut with a flat face at the base.

CABOCHON A type of cut in which a gemstone is cut into a round or oval with a plain, domed upper surface.



Star ruby cut into a cabochon

CARAT The standard measure of weight for gemstones. One metric carat equals 0.2 g.

CHATOYANCY The tiger's eye effect shown by some stones, such as chalcedony, when they are cut into cabochons.

CLEAVAGE The way in which a crystal splits apart along certain well-defined planes according to its internal structure.

COMPOSITION The fixed or well-defined chemical makeup of a mineral.

COMPOUND A chemical compound is made of two or more elements joined together chemically, which can only be separated by heat or great pressure.

CORE The area of iron and nickel at the center of the Earth.

CRUST The thin outermost layer of the Earth.

CRYSTAL A naturally occurring solid with a regular internal structure and smooth external faces.

CRYSTALLINE Having a crystal structure.

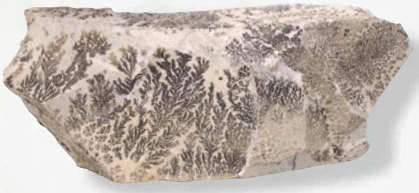
CUT The way in which a gemstone is cut into a number of flat faces called facets, or rounded and polished.

Calcite crystal

DENDRITES Fernlike growths of crystals found lining the cracks and joints in rocks.

DICHROIC A term used to describe a gem that appears to be two different colors when viewed from different directions.

DIFFRACTION The splitting of white light into its constituent colors.



Dendrites of the mineral pyrolusite

DOUBLET A composite stone made of two pieces cemented or glued together.

DURABILITY The capacity to last for a long time without wearing out.

EROSION The wearing away of the surface of the land and rocks by a moving medium, such as water, ice, or the sea.

FACET One flat surface of a cut gemstone.

FACETING Cutting and polishing gems into flat surfaces called facets.

FIRE A term used for dispersed light. A gem with strong fire is unusually bright.

FLUORESCENCE Colored light that radiates from a mineral when it is exposed to invisible ultraviolet light.

Fluorescent crystal

GEMSTONE A decorative mineral or organic substance prized for its beauty, durability, and rarity.

GEODE A cavity within a rock that is lined with crystals that grow toward the center.

GIRDLE The widest part around the middle of a cut stone, where the top half (the crown) and the bottom half (the pavilion) meet.

HABIT The shape in which a crystal naturally occurs. Crystal habit is a key factor in identifying minerals.

IDIOCHROMATIC A term used to describe minerals, such as sulfur, whose color is part of their chemical composition.

INCLUSIONS Material (usually a mineral) trapped within another mineral.

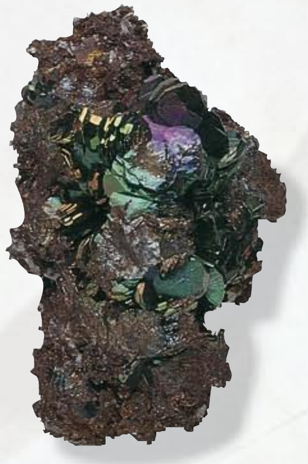
INTERGROWN When two or more minerals grow together and interlock.

Idiochromatic sulfur

IRIDESCENCE A rainbowlike play of colors on the surface of a mineral, similar to a film of oil on water.

LAPIDARY A craftsman who is skilled at cutting gemstones to obtain the best optical effect.

LAVA Magma from within the Earth that erupts to the surface from volcanoes.



Iridescent hematite crystals

LODESTONE A piece of magnetite, a naturally occurring magnetic iron oxide.

LUSTER The way in which a mineral shines. Its luster is affected by the way in which light reflects off the surface of the mineral.

MAGMA Molten rock deep below the Earth's surface.

MANTLE The layer of the Earth between its core and its crust.

MASSIVE A term used to describe minerals that have no particular shape.

MATRIX A term for the main body of a rock.

METAMORPHOSE To undergo recrystallization in a solid rock, leading to a change in mineral compostion and texture. In rocks, this is usually caused by the effects of heat and temperature.

Magma

MICROCRYSTALLINE A mineral structure in which the crystals are too small to be seen with the naked eye.

MINERAL A naturally occurring inorganic solid with regular characteristics, such as crystal structure and chemical composition.

MIXED CUT A gemstone cut in which the facets above and below the girdle follow different styles, usually a brilliant cut above and a step cut below.

MOHS' SCALE A scale devised by the Austrian mineralogist Friedrich Mohs that measures the hardness of minerals according to what they are able to scratch, on a scale from 1 to 10.

NACRE Tiny platelets of calcium carbonate that create the soft sheen on pearls and inside some seashells as they reflect light.

Nacre inside shell

OPALESCENCE Milky blue form of iridescence.

OPAQUE Does not let light pass through it.

ORGANIC GEM A gem made by, or derived from, one or more living organisms.

PEGMATITE Igneous rocks containing very large crystals, which have formed from the very last water-rich magma to crystallize.

PENDELOQUE CUT Lozenge-shaped cut often used for flawed gems.

PHANTOMS Regular inclusions that occur within a crystal, such as parallel growth layers.

PIZOELECTRICITY A property of quartz crystals. Pressure on a crystal creates positive and negative charges across the crystal.

PLEOCHROIC A term used to describe a gemstone that looks as if it is two or more different colors when viewed from different directions.

PRISMATIC A term used to describe a crystal that is "pencil-like," with elongated crystals.

PROPERTY A characteristic of a mineral, crystal or gemstone, such as its color or habit.

REFRACTIVE INDEX (RI) A measure of how light rays slow down and bend as they enter a gemstone. One of the properties used to identify gems.

RESIN A sticky substance from certain plants.

RHOMB A shape rather like a lopsided cube.

RIVER GRAVELS Deposits of minerals that have been broken away from their host rock and washed downstream.

ROCK A combination of mineral particles. Some rocks contain a variety of minerals and some only one. Rocks may be inorganic, chemical, or biological in origin.

ROUGH A term for the natural state of a rock or crystal before it is cut or polished.

SCHILLER Sheen or iridescence.

SPECIFIC GRAVITY (SG) A property of minerals that is defined by comparing the weight of a mineral with the weight of an equal volume of water.

SPECTROSCOPE An instrument used to identify different gemstones. It reveals the bands of light that a gemstone absorbs.

Coral,
an organic gem

Selenite

STEP CUT A rectangular or square-shaped gemstone cut with several facets parallel to the edges of the stone. It is generally used for colored stones.

STRIATION Parallel lines, grooves or scratches in a mineral.

SYMMETRY, AXIS OF An imaginary straight line through a crystal. If the crystal were rotated about this line, the same pattern of faces would occur a number of times in a full turn.

SYNTHETIC GEMSTONE An artificial stone made in a laboratory that has a chemical composition and properties similar to the natural gemstone from which it is copied.

Step-cut ruby

TABLE CUT A type of step cut with a square table facet and girdle and parallel square facets.

TRANSLUCENT Material that allows some light to pass through it.

TRANSPARENT Material that allows light to pass right through it; able to be seen through.

TWINNED CRYSTALS Two crystals of the same mineral that are joined together at a common plane, known as the twin plane.

VEIN An infilled joint, fissure, or fault. Veins are often made of minerals.

VITREOUS A term used for the glasslike quality of some gemstones. It is used to describe a gem's luster.

Twinned calcite crystals

The Science of BioGeometry

by

Dr Ibrahim Karim

**©1997
BioGeometry Energy Systems Ltd. & Dr. Ibrahim karim.**

Balancing the activities of daily life, achieving harmony with our inner and outer environments, humanizing modern technology, integrating science and spirituality, and discovering the unified scientific reality behind all religions is the work of the science of BioGeometry®.

Just two decades ago everybody was afraid that the end of life on earth would come as a result of a Third world War. We thought that the global extinction of life on earth would come from nuclear warfare and our carelessness towards our environment, endangering plant and animal life; the ozone hole and global warming causing natural disasters everywhere. However, the real potential danger is one that we are barely aware lurking just around the corner.

The age of information carries with it the potential to the global extinction of our civilization. We are continuously increasing the amount of carrier waves needed for the wireless technology of modern communication in the earth’s atmosphere every day. These electromagnetic waves are thousands of times stronger than the level used in the communication in our body cells. The problem is not the saturation of the earth's atmosphere through quantity, but also a detrimental quality. Even people who avoid using high technology are not immune. No one is immune even if one lives at the far end of the world or on top of the Himalayas, because these are carrier waves with penetrating properties. It is like trying to move a breeze through a storm, our immune systems are continuously trying to correct the distortion in the transfer of inner information in our body; very soon the threshold will be reached when a total collapse of our body defenses will take place.

BioGeometry® is a science that deals with the Energy of Shape; it uses shapes, colours, motion, orientation and sound to produce a vibrational quality that balances energy fields. BioGeometrical shapes are two or three-dimensional shapes specially designed to interact with the earth's energy fields to produce balancing effects on multiple levels on biological systems. They were developed and patented by Dr. Ibrahim F. Karim, D.Sc. in Cairo, Egypt, during research since 1968.

To understand the effects of BioGeometrical shapes on the human energy system, we have to recognize that the human body has an energy field around it, which has its own north-south axis. As we move around, the angle formed between our individual axis and that of the earth is constantly changing, and this in turn either strengthens or weakens our energy field. The positive range is very small, vulnerable most of the time, and is a major factor affecting our health and well being. BioGeometrically balanced energy, however, considerably strengthens our energy fields to such an extent that we are not detrimentally affected by changes of orientation. In fact, it appears to cancel obvious energy interactions predicted by currently accepted physical laws.

Research in BioGeometry® was and still is mainly dedicated to the development of a new form of architecture that would enhance the human biological system and give a new meaning to the concept of "Home". To upgrade the energy quality of existing homes and cancel the potentially harmful effects of unchecked energy fields due to the architectural design, furniture layout, electrical wiring and modern appliances, specially designed decorative elements are strategically placed to neutralize negative energy and add a positive quality to it. BioGeometrical shapes when designed or engraved on jewelry have shown positive effects on the body's energy field, and reduce considerably the potential health hazards caused by cellular phones, computers and all other modern appliances.

The impact of geometrical shapes on human energy systems has always been universally recognized. This awareness gradually disappeared, and our "modern" approach is to consider these ancient forms either as symbolic art without function, or attribute them to magical practices. Although the modern development and practices are not directly derived from Ancient Egypt, a very advanced know-how in this field is evident when we analyze and use the shapes that they have developed thousands of years ago.

They must have been able to interact with nature in a more advanced way than we do today, based on the study of the vibrational properties of the geometrical shapes they used in their monuments, art, statues, amulets, and many other aspects of life. The effects of energy went beyond the Pyramid shape; the Ancient Egyptians used it in a very practical way in all aspects of their life. Unlike our modern energy forms that are highly amplified states of energies occurring in nature, this science dealt with forces on a natural level as they occur in nature. That means that this Ancient Egyptian science was more like a language that they used to establish two-way communication with nature. This two-way information flow process was used to establish total harmony in all actions between man and nature, to acquire a deeper knowledge about anything by accessing information about it's working principles on the energy level, and most important of all to influence any action in nature by manipulating its energy patterns to achieve the intended results.

Pythagoras was the first to introduce to the western world the ancient Egyptian way of correlating musical qualities with quantifiable, numerical values. The golden ratio of 1.618 expressed as the ultimate proportion of harmony, beauty and spirituality was used in the design of sacred buildings in Ancient Architecture to produce spiritual energy that facilitated connectivity with spiritual realms through resonant prayer. Popular among spiritually significant shapes are pyramids and hemispheres (e.g. the domes, that are the basis of religious buildings, be it a mosque, a church or a synagogue). These particular shapes are energy emitters; they are shapes that produce a type of penetrating carrier wave which Chaumery and De Belizal named, negative green, (which acts as carrier, like radio waves that carry sound information). The vibrational quality of negative green gives it very strong communication properties, which facilitate resonance with higher realms in prayer. Negative green turned out to have other properties, however, which make it very harmful under continuous exposure. Considerable research into this type of energy has been done by Dr. Karim, and the different components have been identified.

A revival of the Ancient Design Criteria or Canons in modern architecture was attempted by the Swiss pioneer of the modern architecture, Le Corbusier, with his "modular" system, which comprised two scales of dimensions based on the golden ratio.

Dr. Ibrahim F. Karim has done extensive research and found that BioGeometrical shapes have three primary vibrational qualities:

1) Negative green.
2) A higher harmonic of ultra-violet.
3) A higher harmonic of gold.

Only shapes, which produce energy fields with all three components, are BioGeometrical.

The effect of BioGeometrical energy on health is not specific and not precisely predictable. It appears to amplify and balance the energy fields of the body on all levels, and thereby give the body greater power to heal itself. The healing process resulting from a strengthening and balancing of the immune system manifests differently from one person to the other; certain results, however, have been repeatedly observed.

BioGeometrical shapes balance the body energies on different levels; positive effects are usually felt on the emotional, mental, spiritual as well as the physical level. They have been found to be effective over a very broad range, including the protection against harmful radiation emanating from the earth (believed to be a major cause of cancer) and different types of man-made pollution. For specific healing purposes, research is being conducted in collaboration with medical doctors in the science of BioSignatures®, which deals with energy of shape in relation to specific functions of the body organs.

The BioGeometrical Systems Institute Company

The BioGeometrical Systems Institute Company was founded in 1993 by Dr. Ibrahim Karim, D.Sc., and Mrs. Rawya Karim, M.A. It was envisioned as a design center to research and implement the new science of BioGeometry, developed & patented by Dr. Karim. The BioGeometrical Energy system Ltd. is a multi-disciplinary organization working in the following fields:

1. A BioGeometrical design language used in architectural, planning decoration, industrial design and accessories.
2. Energy adjustment on all levels and protection from harmful earth radiation ranging from a building to a whole city.
3. The development and use of BioSignatures to support traditional and alternative medicine.
4. Environmental application and protection from side effects of modern technology. For example electronic and cellular devices
5. Agriculture research in organic planting eliminating pesticides and prolonging shelf life.

BioGeometry: The Egyptian Art of Energy Balancing

by

Leanna Joyner

BioGeometry has been called the Egyptian version of Feng Shui but its unique methods and effects are not found in any other system. BioGeometry combines previously hidden methods used in the Inner Temple Sciences of Ancient Egypt with modern European subtle energy detection tools. Developed by renowned Architect and energy researcher Dr. Ibrahim Karim of Cairo Egypt, BioGeometry has been shown to have astonishing benefits for humans, animals, plants, and the environment.

BioGeometry utilizes Nature's own design language of geometric form, color, sound and motion to balance the Energy in all living systems. It also features profound methods to transmute harmful environmental energies into beneficial ones. Robert Gilbert Ph.D., an expert in Sacred Geometry and the author of the only English language texts on BioGeometry, identifies BioGeometry as an essential key to understanding the Living Energies which every spiritual tradition uses for Healing and Spiritual Development.

“Working directly with Dr. Karim and his experts, I found they had unique insights into practical energy work. I'm still in awe of how clearly they explain energy principles which are usually thought to be very mysterious; when you work with the Egyptians, one piece of essential knowledge after another just seems to fall into place. For example, virtually every tradition knows about the Golden radiance which appears in the energy field of great Saints and Masters, but only this group of Egyptians can show you simple methods anyone can use to detect that energy, create it with methods including movement and geometric forms, and also practically apply it to balance and heal a variety of energy problems. These Egyptian methods, now that they are finally becoming public, are going to have a powerful impact on how we understand and work with healing energies,” Dr. Gilbert explained.

Although BioGeometry makes no claims, multiple scientific and medical studies suggest its potential to create powerful energy effects. Just a few examples:

The Egyptian National Hepatitis C Research Project under Dean Taha Khalifa M.D. at Al Azhar University's Pharmaceutical School announced publicly that the best results in the entire study were enjoyed by those given the appropriate BioGeometry patterns to wear. Although Dr. Karim insists that BioGeometry is simply a supportive modality that he makes no medical claims for, the publicity led to Dr. Karim becoming a celebrity with his own television show on holistic health and spiritual development.

The Egyptian National Research Centre discovered that simple BioGeometry forms could stop the replication of Bacteria, a result so astonishing that they created a special project to study the effect of Geometric Forms on Living Systems under the leadership of Dr. Karim.

A project evaluated by an official of the Egyptian Department of Agriculture found that chickens grew healthier and faster in an environment which was energy balanced by BioGeometry methods than they did with antibiotics and growth hormones.

Professor Peter Mols of Wageningen Agriculture University in Holland found that BioGeometry energy methods could be used in place of pesticides and artificial fertilizers to grow healthy organic crops.

The Swiss village of Hemberg suffered both human and animal health problems after a powerful Microwave antenna array was placed in the center of town. Dr. Karim balanced the electromagnetic pollution problem for the entire area, leading to such a dramatic improvement in living conditions (and the return of birds and other animals which had fled the area) that he was given the Key to the City by the Mayor and featured on national Swiss news programs.

”In my personal experience, I've used BioSignatures (precise BioGeometry energy patterns linked to different parts of the body) to help free me from the chronic neck and spine pain I suffered from a severe car accident,” said Dr. Gilbert. “We get incredible reports all the time from students regarding the power of the BioGeometry methods, but we don't make them public. Frankly, many just seem unbelievable if you don't understand how BioGeometry works. Also, we want everyone to understand that we don't make any medical claims whatsoever; we simply teach the principles and methods and leave it to the students to find out for themselves how powerful BioGeometry can be in many cases.”

BioGeometry has only been taught publicly for a short period of time. But already several hundred Americans have been trained in the Art - first by Dr. Karim and now by Dr. Gilbert (Dr. Karim no longer teaches Foundation trainings in BioGeometry, and rarely teaches at all.) Students have applied BioGeometry to a wide range of fields including conventional and alternative Health Care, Environmental Restoration, Architecture and Interior Design, Feng Shui, Spiritual Practices, Landscape Design, Agriculture and Gardening, and Graphic Design.

“Basically, BioGeometry teaches practical methods to work with the fundamental energies of Creation. It can be applied to virtually any field of work, and blends with any methods one currently uses. In collaboration with Dr. Karim, we've set up the Foundation Training so that we can teach all the essential BioGeometry methods to detect, create, and apply beneficial energies in just one week. We also make sure students understand what the Egyptians call Energy Alchemy, how to transmute harmful environmental energies into helpful ones. But perhaps most importantly, BioGeometry doesn't ask for students to take anything on faith. Rather it provides the tools to directly detect and monitor energies which shape the world around us,” said Dr. Gilbert. “I'm deeply grateful to the Egyptians who have made these secrets public for the first time. It's having a profound effect on a lot of people's lives.”

Dr. Robert J. Gilbert is founder of Vesica: Spirit and Science Resources and the first non-Egyptian ever granted permission to teach certified trainings in BioGeometry. Vesica is offering a rare BioGeometry Foundation Training in San Diego from October 9 -15, 2004. More information on BioGeometry, the foundation training and registration is available online at www.vesica.org

---

http://www.amcham-egypt.org/Publications/BusinessMonthly/August%2099/Followup.asp ---

Those companies embracing the growing trend of custom designed, built-from-scratch workplaces might want to give Dr. Ibrahim Karim a call --- that is unless they want to risk spending millions to produce an office full of creativity-destroying energies.

According to Karim, a proper office requires more than just comfortable chairs and soft lighting. As inventor of a science he calls biogeometry, Karim claims he can manipulate energy fields to create an office environment that produces healthy, happy, creative workers.

“We can transform any building into an energy balancing and protective second skin,” he said. “You can raise the quality of life of [the employees]. They’ll feel more energized, more creative.”
Karim, a Zurich-trained architect and consultant to the Ministry of Scientific Research, said that the average office worker in Egypt or anywhere else toils away amid “architectural pollution” that can wreak havoc on both his body and mind. Each employee, Karim said, is like a “breeze trying to move through a heavy storm” of disruptive energy and electronic noise. “In any office, in any city, you’ll find a mess.”

But biogeometry, Karim claimed, is the answer. After “measuring the interaction of energy fields” in a room or building, Karim will recommend changes in room color, furniture shape or orientation. Specially designed picture frames can be used to emit balancing energy. “Stand in front of one, and you’ll feel better within five minutes,” Karim said. Electronic devices such as computers or cellular phones inherently produce negative energy, but they can be rendered less disruptive by engraving special symbols into their sides.

On the surface, biogeometry seems to borrow liberally from feng shui, an Asian design philosophy that attempts to manipulate energy through shape, color and decor. But Karim said biogeometry is based in modern physics, not feng shui, which anyway has become watered-down and faddish. “The old masters are gone, and the essence has been forgotten,” Karim said.
There’s another difference. Feng shui is an accepted part of Asian architectural practice, and a feng shui consultant is brought in at the start of construction projects in many Asian cities. Biogeometry isn’t quite there yet in the eyes of the local architectural or business community. Karim hasn’t been contracted to apply his philosophies that often in Egypt. He recently worked on energy adjustment at a Montessori school in Maadi, and he’s building his own re-sort in Ain Sukhna where everything from the furniture to the landscaping will be designed to give an energy boost. “We’re working on all levels,” he said. “It’s a health spa where the most important activity is just being there.”

Karim gets a far more receptive reaction overseas. He’s spent several months working on energy modification at the industrial design building at Eindhoven in Holland, where he seems to be regarded as a genuine visionary. Most likely, Karim’s local profile will rise once Egyptians realize that the foreigners are taking him seriously.

Among Karim’s architectural peers, reactions to his theories ranges from enthusiastic support to polite bemusement. Karim’s peers seem to give him a lot of leeway – partly because his father, Sayed Karim, is a legendary Cairo Uni-versity architecture professor who helped design Medinat Nasr, and partly because Karim carries the fervor of a true believer, offering free seminars and classes for curious architects and designers. Even architects who consider Karim a nut consider him a sincere nut.

“Give the guy a chance,” said Cairo University architecture and urban planning professor Sayed Ettouney. “You know somebody is a crook when they’re after money or power. But he’s offering his knowledge as a service. He’s spending his own money on this.”

Egypt’s medical establishment reacted less charitably when Karim ventured into their field by claiming he could regulate the body’s energy levels and heal the sick by using special “biosignature” symbols hung from necklaces or bracelets. In February, Karim appeared on the popular interview show Talk of the City, along with patients who said they’d been cured by his biosignatures. The response was immediate and twofold: first, he was denounced in print by the Doctors’ Syndicate and the minister of health; second, his Maadi office was swamped by desperate crowds seeking miracle cures.

The controversy, and the fear that his office might be overrun, led Karim to cut back on seminars and medical treatments months ago. The gate of his Maadi villa now bears a large sign turning away medical cases with the blunt pronouncement, “This is an architecture office.” But the calls keep coming.

“We get calls every day from people who think he can help them have children or cure their polio,” said Karim’s office director. “It’s like a he’s a fugitive. We have to hide him.”

Like any good magician, Karim is reluctant to get into the specifics of his work. Ask him to describe the basics of what shapes or colors create a healthy office energy level, and he'll say he doesn't want to get into "ready-made solutions." Ask just how he discovered that this particular squiggly line can help cure liver failure or fight depression, and he'll smile and say he worked on it for many years. Even his own students and devotees are stumped.

"We asked where these come from, and he says, 'Guys, that's a very big subject. Let's not get distracted,'" said Mu-hammed Samir, a young architect who took several of Karim's free training seminars. But despite the absence of explanations, Samir believes that Karim is genuinely on to something. "People have been treated successfully. The re-sults are in front of us," he said. "Where it comes from, we don't know and he won't say."

BioGeometry: The Egyptian Science of Energy --- An Interview with Dr. Robert J. Gilbert

[Excerpts]

What is BioGeometry?

BioGeometry is remarkable for how vast the possibilities are for applying it in virtually any field you can name! Because BioGeometry deals with the fundamental energies of Creation, those which are essential to human health and higher consciousness, it can be used to support and empower many different approaches to energy work. What I find particularly valuable are the tools which BioGeometry offers so that anyone can work tangibly with different energies rather than "assume" the energies are present or just follow someone else's techniques and hope for the best! BioGeometry offers methods to directly detect, measure, create, and transmute specific qualities of energy, so that you really know the effects you are creating with your energy work. It really is a huge step forward in the human race's ability to understand and work responsibly with energy fields. And I believe this is just the beginning; many of those who train in BioGeometry will use this knowledge to further advance humanity's work with energy into even more advanced levels which most of us can't even imagine today.

BioGeometry is a powerful science which shows how to use shapes, patterns, colors, sounds, and motion to create specific energy effects. It clearly identifies core principles as well as providing a wide range of practical techniques. BioGeometry does not ask for the student to take anything on faith, rather it provides the tools to directly detect and monitor the energies which shape the world around us. BioGeometry reveals publicly for the first time many of the ways which spiritual energy works in the world to create life, health, and consciousness, information which was previously restricted to small groups of spiritual initiates. Put simply, BioGeometry provides critical and unprecedented insights into the use of living energy for beneficial purposes; its simple but extremely powerful techniques can be used by anyone to help humans, animals, plants, and/or the environment.

Can you give us any concrete examples of how BioGeometry has been applied in specific fields or projects?

Absolutely. BioGeometry has been studied and applied in a wide range of fields and projects, including studies at Egyptian and European Universities. Here is just a short list of successful studies:

The Egyptian National Research Centre determined that BioGeometry forms could stop the replication of Bacteria, a result which they stated in their report that they could not explain according to modern scientific theory.

Al Azhar University in Cairo conducted a national Hepatitis C Research Project under the sponsorship of the Egyptian Government, in which they evaluated a wide range of Pharmaceuticals and treatments that might help Hepatitis C sufferers. One of the methods evaluated was BioGeometry, with a particular group in the study given only a medallion with particular BioSignatures on it to correct their energy imbalances. At the end of 6 months, Dr. Taha Khalifa who headed the study announced on national Egyptian television that the most successful results in the whole study (with 90% normalization of enzyme levels on average, and some subjects with complete viral clearance) were enjoyed by the patients who were in the BioGeometry group.

A project evaluated by an official of the Egyptian Department of Agriculture found that chickens grew up healthier and faster in an environment which was energy balanced by BioGeometry methods than they did with Antibiotics and Growth Hormones.

Prof. Peter Mols of the Wageningen Agriculture University in Holland found that BioGeometry energy methods could be used in place of Pesticides and Artificial Fertilizers to grow healthy organic crops with a greatly extended shelf life.

A 1998 agricultural project on the Red Sea headed by Adel Ammar discovered that crops could actually grow better in salt water than in fresh water if the salt water was treated with BioGeometry energy methods.

This is not even to mention the tremendous amount of anecdotal evidence from people who report having all types of different conditions helped by BioGeometry methods; even a Reuters New Service article carried by CNN.com and ABCNews.com contained such reports. Of course we do not make any medical claims whatsoever for BioGeometry; no system that uses subtle energies can make such claims, since the dominant medical and scientific model asserts that these subtle energies don't even exist. So we just tell people to learn the system and make up their own minds from the results they get!

What the Ancient Egyptians Knew... And Modern Scientists Can't Explain

CAIRO EGYPT, August 5 1993: A team of researchers at the Egyptian National Research Centre watches as an Egyptian Architect places a simple geometric form over a culture of bacteria. Reputed to be a master of the lost energy science of Ancient Egypt, the Architect has been brought to the Centre to test his ability to create specific energy effects through the use of shapes, sounds, colors, and movements. The researchers are certain that they will easily discredit such 'nonsense' by designing controlled experiments to test his abilities.

To their amazement, the Architect's claim to be able to stop the replication of the bacteria through the subtle energy emitted by a simple geometric form proves true. In the report of the experiment released by the Head of the Department of Microbial Chemistry, he notes "quite a noticeable cessation of the growth of Saccharomyses cerevisiae was observed... the essence of this type of interaction seems to surpass explanation through our traditional and classical knowledge in basic science."

After this success, other scientists and researchers took up the challenge of testing the Egyptian Architect's energy methods; in every case they are confounded by the powerful effects:

Al Azhar University in Cairo conducted a national Hepatitis C Research Project in which they evaluated a wide range of Pharmaceuticals and alternative treatments. One of the methods evaluated was a medallion which held hundreds of tiny energy patterns termed 'BioSignatures', which the Architect had determined would balance the energy of Hepatitis C sufferers. At the end of 6 months, Dr. Taha Khalifa, head of the study, announced on national Egyptian television that the most successful results in the whole study — with 90% normalization of enzyme levels on average, and some subjects with complete viral clearance— were enjoyed by the patients whose only treatment had been wearing the medallion.

Professor Peter Mols of Wageningen Agriculture University in Holland found that BioGeometry energy methods could be used in place of Pesticides and Artificial Fertilizers to grow healthy organic crops with a greatly extended shelf life.

An agricultural project on the Red Sea headed by Adel Ammar discovered that crops could actually grow better with salt water irrigation than in fresh water if the salt water was first treated with these subtle energy methods.

Biogeometry Shapes & Methodology for Biological Energy Balancing

WO2005062691

7-14-2005

KARIM IBRAHIM FAHMY (EG)

Application number: WO2003EG00017 20031231
Priority number(s): WO2003EG00017 20031231
Also published as: AU2003287943 (A1)

Abstract ~ Geometric shapes and techniques, along with the methodology behind them, invented to produce a qualitative energy balancing effect on biological systems, be it human beings or otherwise. This results in a positive effect on biological functions, either preventative or healing, and protection from environmental energy disturbances. The methodology introduced by the inventor is the discovery of the qualitative energy components of earth energy power-spots {specifically those components are qualitative higher harmonics of the frequencies of gold and ultra-violet, and a carrier wave in the negative green of the energy spectrum} and development of geometric shapes and techniques to reproduce and amplify that energy balancing quality. This methodology has been termed/copyrighted "BioGeometry" by the inventor. The geometric shapes and techniques work either directly through proximity to the biological system or from within its surrounding environment, or by superimposing on a radiating energy source that reaches the biological system. The two techniques are: (1) Using two of the shape (Fig. 4) as geometric polarizers and orienting them in relation to a central axis to produce the energy balancing quality as in (Fig 7) and termed "BioGeometry Dial", (2) Using shape (Fig. 4) as an individual geometric polarizer and aligning samples of materials from the biological system itself or its environment to produce the energy balancing effect (Fig. 8) and termed "Energy Balancing Wheel" when in two-dimensional form and "Energy Balancing Sphere" when in three-dimensional form.

Biosignatures: Linear Diagrams for Biological Energy Balancing

WO2005062690
7-14-2005
KARIM IBRAHIM FAHMY (EG)

Application number: WO2003EG00016 20031231
Priority number(s): WO2003EG00016 20031231
Also published as: AU2003287942 (A1)

Abstract ~ Linear diagrams (Figures 1 to 247) tracing and corresponding to the functional paths of subtle energy flow within the organs of the human body to restore proper flow and energy balancing through resonance. This results in a positive effect on biological functions, either preventative or healing, and protection from environmental energy disturbances. The diagrams are activated by the body's peripheral energy field, which is channeled through the linear diagrams, and enters into resonance with the functions of the organs they correspond to. The energy balancing effect and restoration of proper energy flow within the organs can be introduced by the diagrams either by proximity to the human body, or by superimposing on a radiating energy source that reaches the biological system. These linear diagrams have been termed and copyrighted "BioSignatures" by the inventor.

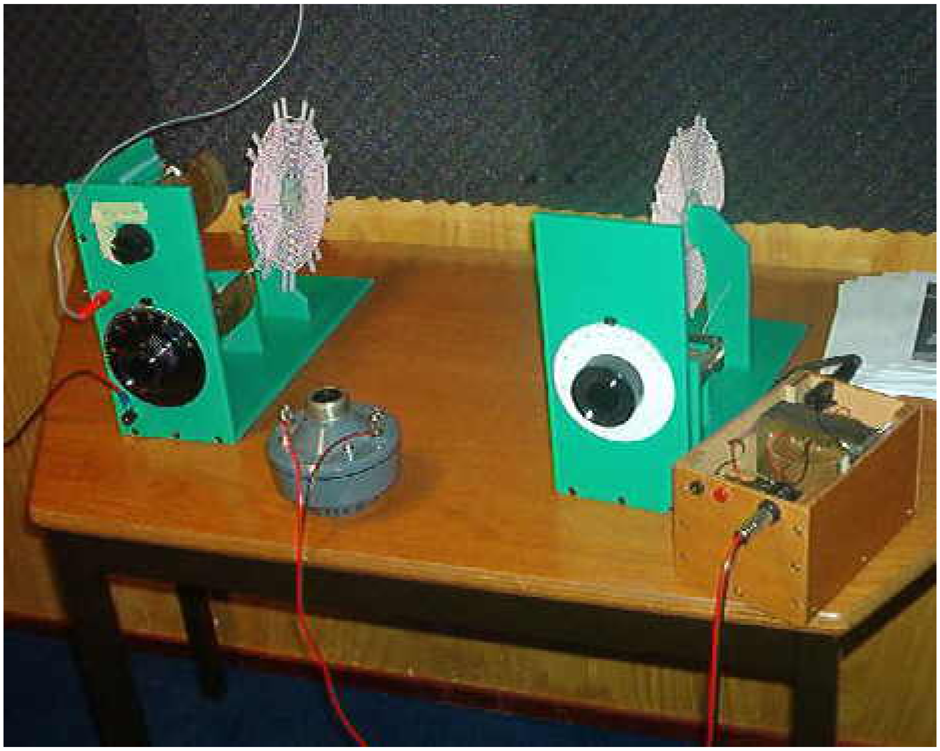
Set 7. DX receiver with two tuned circuits

Back to the index

This receiver has been built in three parts, each part will be described on a separate page:

1- The antenna tuner unit
2- The detector unit
3- The transformer unit



In this receiver I tried to obtain the best possible selectivity and sensitivity, by using a proper circuit and good quality materials.

Before I started building this receiver, I performed many experiments in order to obtain the best possible Q factor in the tuned circuits.
This resulted in circuits with a (unloaded) Q above 1000 for the most part of the mediumwave band.

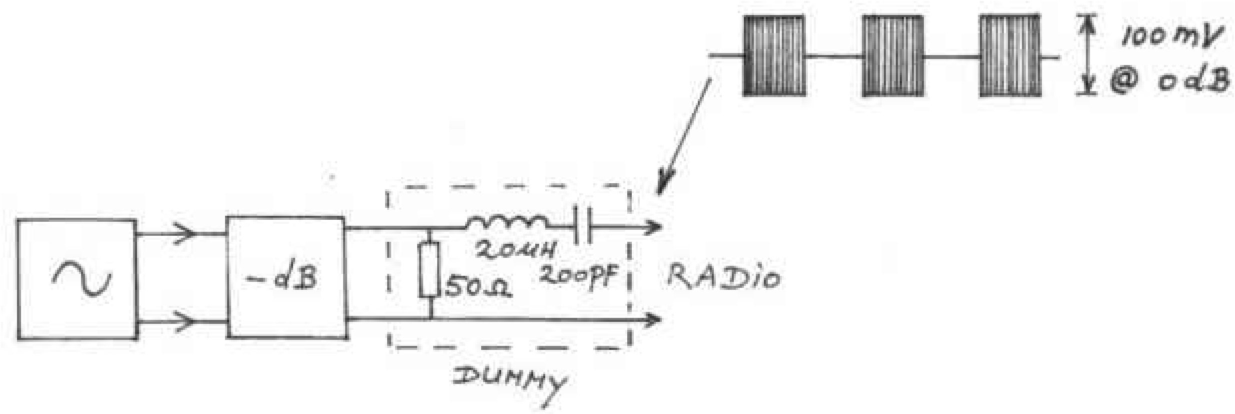
Experiments en measurements carried out with the antenna tuner unit are described here.

The loudspeaker used is a driver unit from a hornloudspeaker, for more information on the sensitivity of this driver unit, see the loudspeakertest.

For a good performance, the coils of the antenna tuner unit and the detector unit must be placed at a distance of 42 cm.
More information and measurements on this topic, you will find here.

The sensitivity of the receiver.

To measure the sensitivity of the receiver, the receiver was connected to a signal generator.
The signal generator was AM modulated with 1000 Hz, this 1000 Hz was a square wave with a modulation depth of 100 %.



Between signal generator and receiver, I connected a variable attenuator and a dummy antenna.

The output voltage of the dummy antenna was 100 mVpp with the attenuator at 0 dB.
This 100 mVpp was measured without connecting the receiver.
When we connect the receiver to the dummy antenna, the output voltage of the dummy antenna will increase, this happens because the coil and capacitor in the dummy antenna then form a part of the resonant antenna unit circuit.

Attenuator setting	Voltage out of dummy antenna (unloaded)	Audio
0 dB	100 mV pp	1600 mV pp
-10 dB	32 mV pp	540 mV pp
-20 dB	10 mV pp	120 mV pp
-30 dB	3.2 mV pp	10 mV pp
-40 dB	1.0 mV pp	< 1 mV pp
-43 dB	0.7 mV pp	sound just audible.

In the last column the amplitude of the detected audiosignal is given, the audio signal is loaded with the transformer unit with speaker.
With the attenuator at -43dB the 1000 Hz test tone was just audible.
The (unloaded) antenna voltage is then 0.7mVpp or 0.25mVeff.
For listening to a normal audio signal, the antenna signal must however be stronger.

With this receiver I took part in national and international receiving contests.

In 2005 this receiver was the 1st price winner in the "Elmer Memorial Crystal Radio DX Contest".

(57) **ABSTRACT**

A resonant transformer connected between a ground terminal and elevated terminal draws current from the earth's electric field through a primary winding of the transformer. An impulse generator applies a high voltage impulse to the primary winding of the resonant transformer to cause current to flow from the ground terminal through the primary winding. The flow of current through the primary winding of the resonant transformer induces a current in the secondary winding, which may be converted and filtered to a usable form, e.g. 60 Hz AC or DC.

POWER RECEIVER FOR EXTRACTING POWER FROM ELECTRIC FIELD ENERGY IN THE EARTH

[0001] This application is a continuation-in-part of prior U.S. application Ser. No. 14/509772 filed 8 Oct. 2014 which claims the benefit of U.S. Provisional Application No. 61/889894 filed 11 Oct. 2013, the disclosures of all of which are incorporated by reference herein in their entirety.

TECHNICAL FIELD

[0002] The present invention relates generally to renewable energy, and more particularly to methods and apparatus for extracting energy from subsurface electrical fields beneath the earth's surface.

BACKGROUND

[0003] The earth and the ionosphere cavity may be viewed as a global electric circuit. Electrical currents are constantly flowing within the earth and its atmosphere. Within the earth, the majority of the earth's energy is carried by extremely low frequency (ELF) and ultralow frequency (ULF) waves in the 0-200 Hz frequency range. The earth's rotating magnetic field and positive lightning are two energy sources that sustain the ELF/ULF waves within the earth and the atmosphere.

[0004] A great deal of research has been devoted to studying the electric field present in the earth's ionosphere cavity. Joseph M. Crawley, the "Fair Weather Atmosphere as a Power Source", Proceedings ESA Annual Meeting on Electrostatics 2011; O. Jefimenko, "Operation of Electric Motors from Atmospheric Electric Field," American Journal of Physics, Vol. 39, Pgs. 776-779, 1971; M. L. Breuer, "Usability of Tapping Atmospheric Charge as a Power Source," Renewable Energy, Vol. 28, Pgs. 1121-1127, 2003. Numerous attempts have been made in the past to extract electrical energy from the earth's atmosphere. For example, U.S. Pat. No. 1,540,998 to Plauson describes a system for converting atmospheric electrical energy into usable power. These past attempts have been successful in producing only small amounts of power from the electrical field in the earth's ionosphere cavity. The modest success of these experiments compared to results from other renewable energy sources, such as solar and wind, has tempered further research and prevented widespread use of the electric field in the ionosphere cavity as an energy source.

SUMMARY

[0005] The present invention relates to a power receiver for extracting power from electric fields beneath the earth's surface. In embodiments of the present disclosure, a resonant transformer connected to a ground terminal draws current from the earth's electric field through the primary winding of the transformer. Current flow through the resonant transformer is induced by applying a high voltage impulse to the primary winding. The flow of current through the primary winding of the resonant transformer induces a current in the secondary winding, which may be converted and filtered to a usable form, e.g. 60 Hz AC or DC.

[0006] In some embodiments of the power receiver, the resonant frequency of the resonant transformers is below 200 Hz.

[0007] In some embodiments of the power receiver, the resonant transformer comprises a ferro-resonant transformer.

[0008] In some embodiments, the power receiver further comprises an elevated terminal.

[0009] In some embodiments of the power receiver, the primary winding of the resonant transformer is connected between the ground terminal and elevated terminal.

[0010] In some embodiments of the power receiver, the elevated terminal comprises an upper capacitive plate coupled to the earth's ionosphere cavity.

[0011] In some embodiments of the power receiver, the impulse generator comprises the upper capacitive plate and a spark gap connected between the upper capacitive plate and the primary winding of the resonant transformer. The spark gap comprises a pair of electrodes separated by a gap and configured to generate a spark when a voltage difference between the electrodes reaches a predetermined level.

[0012] In some embodiments of the power receiver, the impulse generator comprises a pulse generator for generating low voltage pulses, a step-up transformer for converting the low voltage pulses provided by the pulse generator to high voltage impulses, and a spark gap connected between the step-up transformer and the primary winding of the resonant transformer to generate a spark responsive to the high voltage impulses from the step-up transformer.

[0013] In some embodiments of the power receiver, the impulse generator comprises a pulse generator for generating low voltage pulses, and a step-up transformer connected to the primary winding of the resonant transformer for converting the low voltage pulses provided by the pulse generator to high voltage impulses.

[0014] In some embodiments of the power receiver, the impulse generator comprises a solid state spark generator.

[0015] In some embodiments of the power receiver, the resonant transformer includes a capacitor connected in parallel with the primary winding.

[0016] In some embodiments of the power receiver, the resonant transformer includes a capacitor connected in series with the primary winding between the impulse generator and the elevated terminal.

[0017] In some embodiments, the power receiver comprises multiple resonant transformers having primary windings connected in parallel between the ground terminal and the elevated terminal.

[0018] In some embodiments of the power receiver, the resonant transformers have different resonant frequencies.

[0019] In some embodiments of the power receiver, the resonant frequencies of the resonant transformers are all below 200 Hz.

[0020] In some embodiments of the power receiver, the resonant frequencies of the resonant transformers are matched to respective Schumann resonances.

[0021] Another embodiment of the power receiver comprises a resonant circuit connected to a ground terminal disposed below the surface of the earth, an impulse generator for generating and applying a high voltage electrical impulse to the resonant circuit to induce current flow from the ground terminal through the resonant circuit, and a power conversion circuit connected to the resonant circuit to convert electrical current flowing through the resonant circuit to a desired form. The resonant circuit has a resonant frequency below 200 Hertz.

[0022] In some embodiments of the power receiver, the resonant circuit comprises a resonant transformer having a primary winding, a secondary winding, and resonant capacitor connected in series with the primary winding.

[0023] In some embodiments of the power receiver, the resonant circuit comprises multiple resonant transformers having primary windings connected in parallel to the ground terminal.

[0024] In some embodiments of the power receiver, the resonant transformers have different resonant frequencies.

[0025] In some embodiments of the power receiver, the resonant frequencies of the resonant transformers are all below 200 Hz.

[0026] In some embodiments of the power receiver, the resonant frequencies of the resonant transformers are matched to respective Schumann resonances.

[0027] Other embodiments of the disclosure comprise a ground terminal for a power receiver. In one embodiment, the ground terminal comprises a ground shaft configured for insertion beneath the surface of the earth, a hollow cylinder surrounding the ground shaft and having a plurality of openings, and a plurality of ground wires connected at one end to the ground shaft. The ground wires are wound around the ground shaft and have free ends protruding through respective openings in the hollow shaft so that rotation of the ground shaft relative to the hollow cylinder causes the ground wires to extend radially into the earth.

[0028] Other embodiments of the disclosure comprise methods of extracting power from the earth. In one embodiment, the method comprises applying a high voltage impulse to resonant circuit coupled to a ground terminal disposed beneath the surface of the earth to initiate resonance in the resonant circuit and induce the flow of current from the ground terminal to the resonant circuit, and converting the current flowing from the ground terminal into the resonant circuit into a useful form.

[0029] In some embodiments of the method, the resonant circuit comprises a resonant transformer including a primary winding coupled to the ground terminal and a second winding coupled to a power converter, and applying a high voltage impulse to resonant circuit comprises applying a high voltage impulse to the primary winding of the resonant transformer.

[0030] In some embodiments of the method, applying a high voltage impulse to the primary winding of the resonant transformer comprises applying an impulse in the range to 10,000 to 40,000 volts to primary winding of the transformer.

BRIEF DESCRIPTION OF THE DRAWINGS

[0031] FIG. **1** illustrates a first exemplary embodiment of a power receiver.

[0032] FIG. **2** illustrates a second exemplary embodiment of a power receiver.

[0033] FIG. **3** illustrates a third exemplary embodiment of a power receiver.

[0034] FIG. **4** illustrates a fourth exemplary embodiment of a power receiver.

[0035] FIG. **5** illustrates a fifth exemplary embodiment of a power receiver.

[0036] FIG. **6**A is an exploded perspective view of an exemplary ground antenna array for the power receiver.

[0037] FIG. **6**B is a perspective view of an assembled ground antenna array before being deployed.

[0038] FIG. **6**C is a perspective view of an assembled ground antenna array after being deployed.

[0039] FIG. **7**A is a side view of an insertion tool for installing the ground antenna array.

[0040] FIG. **7**B is a top view of the insertion tool for installing the ground antenna array.

[0041] FIG. **7**C is a bottom view of the insertion tool for installing the ground antenna array.

DETAILED DESCRIPTION

[0042] Referring now to the drawings, a power receiver for extracting energy from the earth's electric field are illustrated and indicated generally by the numeral **10**. Various embodiments of the power receiver **10** are described and similar reference numbers are used throughout the description to indicate similar components.

[0043] The power receiver **10** converts energy in the ELF/ULF waves to useful form, e.g. 60 Hz AC or DC. The power receiver **10** is essentially a resonance circuit that resonates at the natural resonance frequencies in the earth's electric field. These resonance frequencies, known as Schumann resonance frequencies, occur at 7.83 Hz, 14.3 Hz, 20.8 Hz, 27.3 Hz, and 33.8 Hz. A high voltage impulse initiates resonance within the power receiver **10**. In the resonant mode, the impedance of the power receiver **10** is reduced to near zero thus inducing ground currents to flow into the power receiver **10** where the ground currents are converted to useful form.

[0044] FIG. **1** illustrates a first embodiment of the power receiver **10**. The power receiver **10** comprises a resonant transformer **30** connected between an elevated terminal **15** and ground terminal **25**. In this embodiment, the elevated terminal **15** is capacitively coupled to electric fields within the earth's ionosphere cavity and functions as an upper capacitive plate. A lower capacitive plate **20** is connected to the ground terminal **25** beneath the surface of the earth.

[0045] The resonant transformer **30** comprises a primary winding **35**, secondary winding **40**, ferromagnetic core **45**, and capacitor **50**. One end of the primary winding **35** is connected to the lower capacitive plate **20** and ground terminal **25**. The opposite end of the primary winding **35** is connected via a spark gap **90** to the elevated terminal **15**. The capacitor **50** is connected in parallel with the primary winding **35** of the resonant transformer **30** to form an LC circuit **55** with a resonance frequency range of between about 0.1 and 200 Hz. In a preferred embodiment, the resonant transformer has a Q of about 10 or greater and resonance frequency in the range of about 0.1-200 Hertz. For example, the resonant transformer **30** may have a resonance frequency of about 7.83 Hz, the fundamental Schumann resonance frequency. The secondary winding **40** of the resonant transformer **30** is connected to a power converter **110** as will be hereinafter described in greater detail. The power converter **110** converts the energy extracted from the earth's electric field by the power receiver **10** into a usable form for driving a load **140**.

[0046] The elevated terminal/upper capacitive plate **15** comprises an insulated, dish-shaped plate with a large radius of curvature. The capacitance and resistance of the elevated terminal is chosen for receiving broadband electric field frequencies in the 0-200 Hz range. The upper capacitive plate **15** is sized to maximize to the extent practical coupling with the electric field in the earth's ionosphere cavity.

[0047] The lower capacitive plate **20** is also a dish-shaped plate with a large radius of curvature. One function of the lower capacitive plate **20** is to collect charge from the earth's ground currents and provide an instantaneous source of current as hereinafter described. The capacitance and resistance of the lower capacitive plate **20** is selected to promote the flow of current from the ground with minimal losses.

[0048] The spark gap **90** connected between the elevated terminal **15** and resonant transformer **30** comprises a pair of electrodes **95**, **100** separated by an evacuated air gap **105**. Electrode **95** is connected to the upper capacitive plate **15**. Electrode **100** is connected to the resonant transformer **30**. The spark gap **105** prevents electrical discharge from the upper capacitive plate **15** to the earth's ionosphere cavity. The spark gap **90** in combination with the elevated terminal **15** function as an impulse generator that applies a high voltage impulse of about 10,000-40,000 volts to the primary winding **35** to initiate resonance in the transformer **30**.

[0049] In operation, the capacitive coupling of the upper capacitive plate **15** induces a high voltage operating current in the upper capacitive plate **15**. The upper capacitive plate is connected to a first electrode **95** to the spark gap **90**. When the voltage difference between the electrodes **95** and **100** reaches a threshold, a spark forms across the electrodes **95**, **100** and a high voltage impulse is applied to the primary winding **35** of the resonant transformer **30**. This high voltage impulse initiates resonance within the transformer **30**.

[0050] In resonant mode, the impedance of the resonance transformer is reduced to nearly zero allowing current to flow from the capacitive plate **20** and ground terminal **25** through the primary winding **35** of the transformer **30**, which in turn induces current in the secondary winding **40**. Power converter **110** converts the current flowing through the secondary winding **40** into a usable form for driving a load **140**. The transformer **30** will continue to resonate for a short period of time. By providing high voltage impulses to the primary winding **35** of the resonant transformer **30** at periodic intervals, it is possible to maintain a continuous flow of current from the earth into the resonant transformer **30**, thus producing a continuous supply of power.

[0051] FIG. **2** discloses a second embodiment of the primary receiver **10**. This embodiment includes a resonant transformer **30** connected between an elevated terminal **15** and ground terminal **25**. The resonant transformer **30** comprises a primary winding **35**, secondary winding **40**, ferromagnetic core **45** and a high voltage capacitor **50**. One end of the primary winding **35** is connected to the ground terminal **25**. The opposite end of the primary winding **35** is connected to the elevated terminal **15**. The capacitor **50** has a capacitance of about 0.01 micro-farads. In contrast to the previous embodiment, capacitor **50** is connected in series with the primary winding **35** and elevated terminal **15** and forms a LC circuit **55** with a Q of about 10 or greater and a resonance frequency in the range of about 0.1 to 200 Hz. In a preferred embodiment, the resonance frequency of the transformer **30** is 7.83 Hz, the fundamental Schumann resonance frequency. An impulse generator **60** is connected between the primary winding **35** of the resonant transformer **30** and the series capacitor **50** and applies a high voltage impulse to the primary winding **35** of the resonant transformer **30**. A battery **130** or other external power source supplies power to the impulse generator **60**. As previously described, the high voltage impulse applied by the impulse generator **60** initiates resonance within the resonant transformer **30** inducing current flow from the ground terminal **25** into the primary winding **35** of the resonant transformer **30**. The flow of current from the ground terminal **25** through the primary winding **35** induces current in the secondary winding **40**. Power converter **110** converts the electrical energy in the current flowing through the primary winding **40** into a usable form.

[0052] In contrast to the first embodiment, it is not required to capacitively couple the elevated terminal **15** in the second embodiment to the earth's ionosphere cavity. Rather, the elevated terminal **15** in this embodiment provides lightning protection and dissipates some of the energy flowing into the power receiver **10** to the earth's ionosphere cavity. Also, in contrast to the first embodiment, the capacitor **50** is connected in series between the primary winding **35** of the transformer **30** and the elevated terminal **15**. Those skilled in the art will appreciate that the capacitor **50** could also be connected in parallel rather than series with the primary winding **35** as shown in FIG. **1**. Another difference is that the impulse generator **60** has an external power source. The amount of energy generated by the power receiver **10**, however, is far greater than the energy needed to generate high voltage impulses. The first embodiment does not require an external power source to generate high voltage impulses.

[0053] FIG. **3** illustrates a third embodiment of the power receiver **10**. This embodiment is essentially the same as the embodiment shown in FIG. **2**. The main difference is that a center tap of the primary winding **35** in the resonant transformer **30** is connected to an electrical ground **85**. It should be appreciated that the electrical ground **85** may be different than the earth ground. When the center tap of the resonant transformer **30** is grounded at a distance away from the ground terminal **25** (e.g. 50 ft to 100 ft), the power receiver **10** becomes a transmitter via the ground loop formed.

[0054] FIG. **4** illustrates the power receiver **10** of FIG. **2** in greater detail. The power receiver includes a resonant transformer **30** connected between a ground terminal **25** and an elevated terminal **15**. The ground terminal **25** may comprise a ⅝-inch×8-foot copper ground rod, such as the ERICO 615880UPC. The elevated terminal **15** may comprise a 90% copper mesh formed into a hemisphere with a radius of about 9 inches. The elevated terminal **15** may be elevated at a height of approximately 6 feet above the ground.

[0055] The resonant transformer **30** includes a primary winding **35**, secondary winding **40**, ferromagnetic core **45** and series capacitor **50** configured as previously described. The resonant transformer **30** may have a Q of about 10 and a resonance frequency in the range of about 0.1 to 200 Hz. The resonant transformer **30** may be made using an Allanson transformer (part #1530BP120R) connected in series with a 0.01 micro-farad capacitor, such as the Condensor Products high voltage capacitor (part #TC 103-17-125). The resonant transformer **30** is used in a step-down configuration. The center tap of the resonant transformer **30** may optionally be connected to a ground.

[0056] An impulse generator **60** is connected between the primary winding **35** of the resonant transformer **30** and the series capacitor **50** and applies a high voltage impulse in the range of about 10,000 to 40,000 volts to the primary winding of the transformer **30**. A battery **130** or other external power source supplies power to the impulse generator **60**. The power converter **110** connects to the secondary winding **40**

of the resonant transformer **30** for converting current in the secondary winding of the transformer to a useful form.

[0057] The impulse generator **60** comprises a pulse generator **65** for generating low voltage pulses, a step-up transformer **80** for converting the low voltage pulses from the pulse generator **65** to high voltage pulses, and a spark gap **90** for generating sparks responsive to the high voltage pulses from the step-up transformer **80**.

[0058] The pulse generator **65** comprises a square wave generator **70**, such as a Sinometer VC2002 function signal generator, and solid state relay **75**. The square wave generator **70** generates a digital pulse stream. In one embodiment, the digital pulse stream generates a square waveform with a frequency of about 7.83 Hz. The frequency of the digital pulse stream is selected to match the resonance frequency of the transformer **30**, though such is not necessarily required. The pulse stream output from the square wave generator **70** is applied to the solid state relay **75**. The solid state relay **75** is connected between a battery or other power source and a first winding of the step-up transformer **80**. The battery may comprise a 12 V, 7.0 A/H sealed lead acid battery, such as the ELB 1270A by Lithonia Lighting. The solid state relay **75** functions as a switch that is activated responsive to the waveform from the square wave generator **70** to provide a continuous stream of low voltage pulses from the battery to the first winding of the step-up transformer **80**. A 1 ohm resistor is connected between the solid state relay **75** and step-up transformer **80**.

[0059] The step-up transformer **80** may comprise a Transco 15 kV, 30 mA neon sign transformer (part #S15612). The step-up transformer **80** converts the low voltage pulses from the pulse generator **65** to high voltage pulses that are applied to the spark gap **90**. The step-up transformer has a 0.5 micro-farad capacitor connected in parallel with the primary winding of the step-up transformer **80**. The step-up transformer produces pulses at the output of about 30,000 to 40,000 volts.

[0060] The spark gap **90** comprises a pair of electrodes **95**, **100** separated by an air gap **105**. A suitable spark gap electrode pair is the Information Unlimited SPARK05 ¼-inch×1-inch tungsten electrodes. As previously described, when the voltage potential between the electrodes **95**, **100** reaches a threshold, a spark forms between the electrodes **95**, **100** and supplies a nearly instantaneous, high voltage impulse to the primary winding **35** of the resonant transformer **30**. This high voltage impulse initiates resonance in the resonant transformer **30** inducing current flow from the ground terminal **25** through the primary winding **35** of the resonant transformer **30**.

[0061] The power converter **110** comprises a bridge rectifier **115**, filter capacitor **120**, charge controller **125**, and inverter **135**. A suitable rectifier is the Micro Commercial Components 10 amp, 1000 volt bridge rectifier (Part #GBJL 1010). The bridge rectifier **115** converts the AC current flowing through the secondary winding **40** of the resonant transformer to a DC current. A filter capacitor **120** removes unwanted frequencies from the DC current. A suitable capacitor **120** is Cornell Dubilier 1000uF 450VDC capacitor (part #383LX102M450N082). The filter capacitor **120** has a capacitance of about 1000 micro-farads. The DC current is input to the charge controller **125**. The charge controller **125** may, for example, comprise a maximum power point tracking (MPPT) charge controller, such as a Tracer 4215 BN MPPT Solar Charge Controller, which is commonly used in solar power generating systems. The charge controller **125** applies a small amount of energy to a battery **30** to charge the battery **130**. As previously noted, the battery **130** serves as a power source for the impulse generator **60**. The remaining current is supplied to an inverter **135**, which converts the DC current to an AC current with a desired voltage and frequency, e.g., 120 volts/60 Hz AC. A suitable inverter **135** is the 1500 W Pure Sine power inverter (AIMS) (part #PWRI1500125).The power converter **110** as shown in FIG. **4** may be utilized in the embodiment shown in FIGS. **1**, **2** and **3**.

[0062] FIG. **5** illustrates a power receiver **10** according to another embodiment. The power receiver **10** comprises a plurality of resonant transformers **30** connected between a ground terminal **25** and elevated terminal **15**. Each of the resonant transformers **30** comprises a primary winding **35**, secondary winding **40**, ferromagnetic core **45** and series capacitor **50**. The primary windings **35** of the resonant transformers **30** are connected in parallel. The secondary windings **40** are connected in series with the power converter **110**. An impulse generator **60** applies a high voltage impulse to the primary windings **35** of the resonant transformers **30**. A battery **130** or other external power source supplies power to the impulse generator **60**. The power converter **110** converts the current in the power converter circuit to a usable form for driving a load **140**.

[0063] In one embodiment, each of the resonant transformers **30** shown in FIG. **5** is configured to have a different resonant frequency. In one embodiment, the resonant transformers **30** are configured to resonate at frequencies of 7.83 Hz, 14.8 Hz, 20.3 Hz and 26.8 Hz respectively. Additional resonant transformers **30** could be added to operate at other resonance frequencies.

[0064] FIGS. **6A-6C** illustrate a high quality ground antenna array **200** which may be used as a ground terminal **25**. The ground antenna array **200** comprises a generally cylindrical ground shaft **205** disposed with a hollow cylinder **220** and a plurality of reinforced, heavy gauge ground wires **210** attached at one end to the ground shaft **205**. The ground shaft **205** and ground wires **210** should be highly conductive and have low resistance to supply current from the ground to the power receiver **10**. In one embodiment, the ground wires **210** may be copper or other highly-conductive metal. The end of the ground shaft may be pointed to facilitate insertion into the earth. A connection port on the ground shaft **220** is provided to electrically connect the ground antenna array **220** to the resonant transformer **30**.

[0065] The hollow cylinder **220** has external threads **25** to facilitate insertion into the ground. A rotator nut **235** is fixedly secured to the top end of the hollow shaft **220**. A square shaft **215** protrudes from the top end of the ground shaft **205** into the opening in the rotator nut **235**. FIG. **6B**. A tool **250**, shown in FIG. **7**, engages with the rotator nut **235** and square shaft **215** during insertion of the ground antennas array **200** into the ground as will be hereinafter described.

[0066] The insertion tool **250** is shown in FIG. **7**. The insertion tool **250** includes a tool body **255** having a first socket **260** on one side to fit the rotator nut **235** on the hollow cylinder **220** and a second socket **265** on the other side to fit the square shaft **215** on the ground shaft **205**. Arms **270** extend from the outer periphery of the tool body **255** for manually or mechanically turning the insertion tool **250**.

[0067] Before the antenna array **200** is deployed, the ground wires **210** are wound around the ground shaft **205** with the free ends protruding slightly from respective openings **230** in the hollow cylinder **220** to a distance not to exceed one half (½) the depth of the external threads **225** on the hollow cylinder **220**. FIG. **6**B illustrates the ground antenna array **200** before deployment. FIG. **6**C illustrates the ground antenna array in a deployed configuration.

[0068] Installation of the ground antenna array **200** is performed in two stages. In the first stage, a hole slightly smaller in diameter than the threads **235** of the hollow cylinder **220** is drilled into the Earth to a depth matching the length of the hollow cylinder **220** or slightly longer. The hole is filled with water and the water is allowed to soak into the soil. After the ground is softened, the hollow cylinder **220** is rotated using the insertion tool **250** to insert the ground antenna array **200** into the ground. The first socket **260** of the insertion tool **250** is engaged with the rotator nut **230** and the insertion tool **250** is turned by hand or a mechanized rotating shaft fitted and attached to the tool arms **270** to thread the ground assembly into the hole. During the initial insertion of the ground antenna array **200**, the ground shaft **205** is fixed to the hollow shaft **220** and rotates with the hollow shaft. The hollow cylinder **220** is rotated until it reaches the full depth of the hole.

[0069] Once the ground antenna array **200** has been fully inserted into the earth, the insertion tool **250** is flipped over and the second socket **265** of the insertion tool **250** is engaged with the square shaft **215**. The insertion tool **250** is turned by hand or a mechanized rotating shaft fitted and attached to the tool arms **270** to rotate the ground shaft **205**. During the second phase, the ground shaft **205** rotates freely inside the hollow cylinder **220**. Rotation of the ground shaft **205** causes the reinforced ground wires **210** to extend radially into the earth. The ground shaft **220** is rotated until the ground wires are fully extended. The ends of the ground wires may be sharpened to aid in the extension of the ground wires during the second phase.

[0070] After the ground antenna array **200** is deployed, a connection cable **280** is attached to a connection port **240** on the ground shaft **220** to electrically connect the ground antenna array **220** to the resonant transformer **30** in the power receiver **10**.

What is claimed is:

1. A power receiver for extracting electrical energy from the earth's electric field, said power receiver comprising:

a resonant transformer connected to a ground terminal disposed below the surface of the earth;

an impulse generator for generating and applying a high voltage electrical impulse to a primary winding of the resonant transformer to induce current flow from the ground terminal through the primary winding of the transformer; and

a power conversion circuit connected to a secondary winding of the resonant transformer to convert electrical current flowing through the secondary winding to a desired form.

2. The power receiver of claim **1** wherein a resonant frequency of the resonant transformers is below 200 Hz.

3. The power receiver of claim **1** wherein the resonant transformer comprises a ferro-resonant transformer.

4. The power receiver of claim **1** further comprising an elevated terminal, and wherein the primary winding of the resonant transformer is connected between the ground terminal and elevated terminal.

5. The power receiver of claim **1** wherein the impulse generator comprises:

a pulse generator for generating low voltage pulses;

a step-up transformer for converting the low voltage pulses provided by the pulse generator to high voltage impulses;

a spark gap connected between the step-up transformer and the primary winding of the resonant transformer to generate a spark responsive to the high voltage impulses from the step-up transformer.

6. The power receiver of claim **1** wherein the impulse generator comprises a solid state spark generator.

7. The power receiver of claim **1** wherein said resonant transformer includes a capacitor connected in parallel with the primary winding.

8. The power receiver of claim **1** wherein said resonant transformer includes a capacitor connected in series with the primary winding between the impulse generator and the elevated terminal.

9. The power receiver of claim **1** comprising multiple resonant transformers having primary windings connected in parallel between the ground terminal and the elevated terminal.

10. The power receiver of claim **9** wherein the resonant transformers have different resonant frequencies.

11. The power receiver of claim **10** wherein the resonant frequencies of the resonant transformers are matched to respective Schumann resonances.

12. A power receiver for extracting electrical energy from the earth's electric field, said power receiver comprising:

a resonant circuit connected to a ground terminal disposed below the surface of the earth, said resonant circuit having a resonant frequency below 200 Hertz

an impulse generator for generating and applying a high voltage electrical impulse to the resonant circuit to induce current flow from the ground terminal through the resonant circuit; and

a power conversion circuit connected to the resonant circuit to convert electrical current flowing through the resonant circuit to a desired form.

13. The power receiver of claim **12** wherein the impulse generator comprises:

a pulse generator for generating low voltage pulses;

a step-up transformer for converting the low voltage pulses provided by the pulse generator to high voltage impulses;

a spark gap connected between the step-up transformer and resonant circuit to generate a spark responsive to the high voltage impulses from the step-up transformer.

14. The power receiver of claim **12** wherein the resonant circuit comprises a resonant transformer having a primary winding, a secondary winding, and resonant capacitor connected in parallel with the primary winding.

15. The power receiver of claim **12** wherein the resonant circuit comprises a resonant transformer having a primary winding, a secondary winding, and resonant capacitor connected in series with the primary winding.

16. The power receiver of claim **12** wherein the resonant circuit comprises multiple resonant transformers having primary windings connected in parallel to the ground terminal.

17. The power receiver of claim **16** wherein the resonant transformers have different resonant frequencies.

18. The power receiver of claim **17** wherein the resonant frequencies of the resonant transformers are matched to respective Schumann resonances.

GEORGE F. DIECKMANN, OF NEW YORK, N. Y., ASSIGNOR OF ONE-FOURTH TO PAUL GMEHLIN, OF SAME PLACE.

ELECTRIC EARTH-BATTERY.

SPECIFICATION forming part of Letters Patent No. 329,724, dated November 3, 1885.

Application filed June 15, 1885. Serial No. 168,690. (No model.)

To all whom it may concern:

Be it known that I, GEORGE F. DIECKMANN, a citizen of Germany, residing in the city, county, and State of New York, have invented a new and useful Electric Earth-Battery, of which the following is a specification.

Earth-batteries, consisting of electrodes buried in the earth, as heretofore constructed, have not been capable of giving an electromotive force greater than that obtainable from a single couple—which is too small for practical purposes—because, if a number of couples or elements were used and connected in series all the couples stood in the same electrolyte and short-circuited one another. By my invention I am enabled to bury a series of couples in the same body of earth and connect them together in series, so as to obtain from such a battery an indefinitely high electro-motive force sufficient for charging storage-batteries, operating electric bells, telegraphic and other purposes, &c.

To this end my invention consists in arranging the electrodes in such a way that the resistance between the electrodes of each couple is small, while the resistance between the couples is relatively large, and connecting the negative electrode of each with the positive electrode of the next by a low-resistance conductor, so that the short-circuiting effect of the couples upon each other may be indefinitely reduced, and the effect is practically the same as if the couple were immersed in separated electrolytes. To arrange the relative resistances so as produce this effect I place the two electrodes of each couple comparatively near together, and the separate couples relatively far apart, so that the resistance between one electrode of one couple and the same electrode of the next couple is very much greater than the resistance between the two electrodes of the same couples, and consequently the short-circuiting effect is reduced comparatively to nothing.

My invention is illustrated in the accompanying drawings, Figure 1 representing my arrangement of electrodes in plan, and Fig. 2 showing them in elevation buried in the earth.

In my battery any electrodes may be used, and they may be of any desired size and shape; but in order to make the internal resistance of the battery as low as possible and obtain a cheap construction, I prefer to form each element or couple of zinc and copper plates or sheets separated the proper distance by a sheet of felt, asbestus, or other suitable non-conducting material and rolled up in a spiral form, as clearly represented in the drawings, by which means I obtain a compact element having a large surface with a small distance between the plates, and consequently a very low resistance. The zinc plate being the one most acted upon should be made the thicker, as I have indicated. Having constructed any desired number of these elements according to the electro-motive required, I bury them in the earth at a proper depth in any desired positions, but relatively far apart, so that the distance between them is great compared with the distance between the two electrodes of any one couple. The negative plate of each couple is then connected with the positive plate of the next through the series, as represented—and the terminals of the battery thus formed are connected with the circuit to be supplied, a telegraph-circuit, as represented, for example. The wires connecting the couples should preferably be insulated where they come near together below ground, to prevent short-circuiting there. I have shown them entirely buried in the earth; but of course they may be laid above ground. The distance apart that the couples should be placed depends upon the resistance of the telegraphic or other working circuit. If its resistance be very high, then the couples should be much farther apart, in order that the difference of potential between one electrode of one couple and the same electrode of the next couple may be high compared with the difference of potential between the two electrodes of the same couple. Similarly, the end couples of the battery should be so far apart with reference to the resistance of the working-circuit that the resistance between them through the earth is great compared with the resistance of the working-circuit, so that the working-circuit will not be short-circuited; or, to express it more accurately, the earth-resistance between the end couples should be so high that the fall of potential through it is great compared with the fall through the working-circuit. This effect is obtained by making the distance between the end couples correspondingly greater than that between adjacent couples—by arranging the couples in a straight line, for example. By thus properly proportioning the resistance between the couples to the circuit-resistance and internal resistance of the couples, the short-circuiting effect may be reduced more or less to an insignificant amount, and any desired electro-motive force obtained from the battery.

I claim as my invention—

1. An earth-battery consisting of a number of couples or elements buried in the earth and connected in series, the two electrodes of each couple being placed near together, while the couples or elements are placed comparatively far apart, whereby the short-circuiting effect of the couples upon each other is avoided, and an indefinitely high electro-motive force obtained.

2. An earth-battery consisting of a number of couples or elements composed of sheet-electrodes rolled up in a spiral form and buried in the earth and connected in series, the couples being arranged comparatively far apart, whereby the short-circuiting effect of the couples upon each other is avoided.

UNITED STATES PATENT OFFICE.

MICHAEL EMME, OF OAKLAND, CALIFORNIA.

GROUND GENERATOR OF ELECTRICITY.

SPECIFICATION forming part of Letters Patent No. 495,582, dated April 18, 1893.

Application filed August 29, 1892. Serial No. 444,391. (No model.)

To all whom it may concern:

Be it known that I, MICHAEL EMME, a citizen of France, residing at Oakland, in the county of Alameda and State of California, have invented certain new and useful Improvements in Ground Generators of Electricity; and I do hereby declare the following to be a full, clear, and exact description of the invention, such as will enable others skilled in the art to which it appertains to make and use the same.

My invention relates to chemical generators of electricity, a prepared body of earth being used as the support and exciting medium for the electrodes or elements. In a generator constructed in accordance with my invention, any desired number of elements may be assembled in the same piece of ground and coupled in series or multiple series to produce the electro-motive force desired. I find that if a series of galvanic couples be inserted in a body of ground so that a straight line will pass transversely through the several couples and the space between the several couples be made large comparatively to the distance between the two elements composing the couples, the couples may be joined for series in the same manner as if they were contained in independent vessels. In order, however, to attain the best results it is necessary to prepare the body of soil immediately adjacent to the two elements composing a couple in a manner which will be hereinafter fully described.

The several features of novelty of the invention will be hereinafter more fully described in this specification and definitely indicated in the claims appended to this specification.

In the accompanying drawings Figure 1 illustrates an earth generator in which the several couples are arranged in series. Figs. 2 and 3 show a cross section of ground containing one couple. Fig. 4 shows wedge shaped electrodes. Fig. 5 shows the co-operation of the internal circuits of the several couples. Fig. 6 shows the means for supplying an excitant or moistening medium periodically to the several couples.

Any character of soil may be adapted for use with my ground generator by saturating that portion of it surrounding the several elements with a suitable solution rich in oxygen, chlorine, bromine, iodine or fluorine, or with a solution of a salt of an alkali. As elements I prefer to use iron as a positive electrode and hard pressed coke carbon for the negative electrode. The positive electrode is preferably a U-shaped bar of iron round in cross section. The two limbs of the U straddle a rod of carbon. The iron should be soft wrought iron. Cast iron also can be used, but I find that cast iron gives a little less electro-motive-force, probably by reason of the percentage of carbon and other impurities contained therein. Magnesium also yields excellent results producing with carbon a voltage of 2.25. Zinc, aluminium or any metal with which the ground and its contained salts or exciting medium will develop electrolytic action may be used with varying results.

In carrying my invention into practice I level a piece of ground of sufficient area to contain the generator. For instance, for three hundred positive elements each twenty inches long and two inches in diameter bent as indicated in Fig. 3, and three hundred negative elements fifteen inches long and three inches in diameter, the length of the piece of ground should be about one hundred feet and its width about three feet. I dig forty-three holes, at a distance of thirty inches apart from center to center, in a line as indicated in Fig. 1. Each hole is ten inches wide and thirty inches broad and of a depth sufficient to contain the elements. The loose soil dug from the ground is mixed with a proper salt or acid to render the generator active. For instance, if the ground is a vegetable mold commercial concentrated nitric acid should be added in sufficient quantity to saturate the soil, and peroxide of manganese or pyrolusite should be mixed with the mass. If the soil be of a sandy character hydrochloric acid or carbonate of soda or potash may be substituted for the materials just mentioned. Should the soil be of a clayey character hydrochloric or sulphuric acid and chloride of sodium may be used, the salt being dissolved in water and poured in the hole before the acid is mingled with the soil. The bottom of the hole is moistened with water and the prepared soil mixed with water to the consistency of a thick paste is then introduced, the composite elements being immersed in it. The several groups of elements thus arranged may be connected in series by conductors as shown in Fig. 1, though the generator will act without any external conductors except the terminal wires. A generator constructed as above described will yield 53.85 volts and fifty-six ampères, developing a total of 3,015.60 watts, or about four horse-power. By increasing the number of cells the capacity of the generator may be correspondingly increased to any desired horse-power. The couples may be joined in simple series or in multiple series. The prepared body of soil should be periodically moistened preferably with the acid with which it was treated when first prepared for action, and in a plant constructed for continuous action I prefer to provide a reservoir as indicated at A in Fig. 6 and run a pipe of a material not attacked by the acid throughout the plant providing nozzles over the several couples so that they may be moistened when desired. With provisions of this nature the soil may be kept in a substantially uniform condition and the generator rendered continuously serviceable. Any accumulation of oxides or other products of the reaction between the prepared soil and the elements may be removed and a clean metal surface exposed for chemical action by raising the positive electrode and then forcing it back into place again. The carbon may be cleansed by simply turning it without lifting it from its place.

I find that the period of activity of the generator during which no addition of salt or acid is required increases with the length of service. For example, during the first day of use the exciting medium should be added after ten hours of work, after which it will yield twenty-six hours of service, and then after another addition of excitant it will yield service for two days, and so on.

In Fig. 1 is represented a generator the several electrodes of which are composed of rods grouped in multiple and arranged as indicated in Fig. 2 where B represents the solid ground and C the mass of prepared soil.

In Fig. 3 is shown a preferable shape of electrodes, D representing an iron electrode and E a carbon.

A wedge shaped electrode as shown in Fig. 4 permits easy withdrawal from the soil and the corrugation increases the extent of active surface.

In Fig. 5 are indicated the internal circuits of the generator. The several couples may be interconnected by conductors placed exterior to the ground as indicated by F or the conductors may be dispensed with, (although inferior results are obtained by such an arrangement) as indicated at G.

The dotted lines Fig. 5 indicate the directions of electro-motive-force in the internal circuits, 1, 2, 3, 4, 5, 6 being in one direction and 7, 8 and 9 in an opposite direction. There is a resultant or differential electro-motive-force which develops current in the external circuit.

I am not prepared to state the cause of constancy of action in the generator constructed as hereinbefore described, but I ascribe it to the mutual assistance of the several elements of the series, each positive element finding a conducting medium to all of the negative elements of the series as indicated by dotted lines in Fig. 5, the solid ground acting as a conducting medium. Thus the internal resistance of the generator is lowered and the output of the generator consequently increased. The fact that such internal circuits actually exist may be demonstrated by the interposition of a voltmeter in the ground between successive pairs of elements; the whole body of earth in the neighborhood of the generator seems to be permeated with stream lines of electric energy. This fact probably assists in some way to prevent polarization of the negative electrodes as the battery acts with great constancy.

Having thus described my invention, what I claim as new, and desire to secure by Letters Patent, is—

1. A generator of electricity comprising a series of galvanic couples each couple being embedded in an electrolytic medium composed of earth mixed to a pasty consistency with an exciting solution the spaces between the several couples being occupied by unprepared earth.

2. A ground generator of electricity comprising a series of galvanic couples embedded in an electrolytic medium composed of earth mixed to a pasty consistency with a suitable excitant and filled in holes formed at intervals in the earth.

3. A ground generator of electricity comprising a series of galvanic couples embedded in the earth and connected in series relation, the distance between the several couples being large compared to the distance between the elements of any couple, and a reservoir for periodically supplying a moistening medium and maintaining the action of the generator.

In testimony whereof I affix my signature in presence of two witnesses.

MICHAEL EMME.

(57) **ABSTRACT**

A method and apparatus for producing electricity using Earth electromotive force is disclosed herein. The method comprises placing a first electrode into a first section of the Earth, typically a hydrocarbon bearing formation. Next, a second electrode is placed into a second section of the Earth, typically in or proximal a water zone. Further, the first and second electrodes are electrically coupling to a boost converter assembly. The boost converter assembly is adapted to convert an input voltage derived from the first and second electrodes to an output voltage higher than the input voltage. An apparatus and electrical system comprising the various components for harvesting Earth energy are further disclosed.

EARTH ELECTROMOTIVE FORCE GENERATION METHOD AND APPARATUS

CROSS-REFERENCE TO RELATED APPLICATIONS

This application claims priority to U.S. Provisional Patent Application No. 61/114,178 filed Nov. 13, 2008, the full disclosure of which is incorporated herein by reference. The aforementioned provisional patent application has the title "Earth Electromotive Generator Apparatus and Method Based Upon Natural Earth Currents," and has the same named inventor as the present application.

FIELD OF THE INVENTION

The present invention relates generally to harvesting energy from the Earth and producing electricity therefrom. More particularly, the present invention relates to providing electricity from electromotive force of the Earth.

BACKGROUND

New energy sources are always desired as the world's energy demand continues to rise. Much of the world's energy is produced from extracting oil and gas from hydrocarbon bearing formations contained within the Earth's strata. Hydrocarbons in the form of oil and gas are usually extracted by drilling wells into these hydrocarbon bearing formations subsurface deep into the Earth's strata.

Often energy producing hydrocarbons remain trapped inside hydrocarbon bearing formations after drilling and practical methods of extraction have been exhausted. These hydrocarbons can provide a source of electrons for use in alternative energy methods. Moreover, in many modern extraction efforts, hundreds of deep wells and steel or metallic casings remain after extraction of the oil and gas has been completed thereby providing access to the hydrocarbon bearing formations.

Certain types of Earth batteries are generally known in the prior art, but lack a means to provide electricity for commercial purposes. Other means of harvesting Earth energy are not know in the prior art. Heretofore, there is a need in the art to improve methods and apparatus to provide a commercially viable energy source from Earth electromotive force generation.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1** is a flow chart describing an exemplary method of the invention for producing electricity from Earth electromotive force according to an embodiment of the invention

FIG. **2** is a side plan view of an apparatus for producing electricity from Earth electromotive force according to an embodiment of the invention.

FIG. **3** is a schematic diagram for an exemplary boost converter circuit of an apparatus for producing electricity from Earth electromotive force according to an embodiment of the invention.

FIG. **4** is an overhead perspective view of a plurality of electrodes from the apparatus creating an electrical system for producing electricity from Earth electromotive force according to an embodiment of the invention.

DETAILED DESCRIPTION

Embodiments of the method and apparatus for providing electricity using Earth electromotive force comprise placing electrodes within sections of the Earth's strata to take advantages of discontinuities therein and boosting the small voltage potential between the electrodes. Embodiments include using discontinuities between two sections of the Earth's strata such as, but are not limited to, (i) a hydrocarbon bearing formation (ii) a water zone, (iii) a geothermal brine formation, (iv) a geothermal hot water formation, (v) a geothermal steam formation, (vi) a basaltic dyke, and (vii) a granite formation.

By extending the electrodes with low resistance conductors to two of the aforementioned sections of the Earth's strata, the discontinuities resulting from redox (reduction-oxidation) chemical reactions creating variations in current and ion flow within the Earth's strata can create a small voltage potential between the two electrodes. With modern boost circuitry, the small voltage potential between the electrodes can then be boosted, converted, and aggregated to provide a voltage source suitable for commercial use.

An exemplary embodiment comprises placing a first electrode into a hydrocarbon bearing formation and a second electrode proximal or directly in a water zone. The first and second electrodes are electrically coupled to a first and second terminal. The first and second terminals are likewise electrically coupled to a boost converter assembly. The boost converter assembly is adapted to convert an input voltage from the first and second terminals into an output voltage higher than the input voltage.

Typically, the first electrode is placed deep below the Earth's surface through the overburden to reach the hydrocarbon bearing formation. Hence, an elongated conductor may be required to allow the first electrode to reach the hydrocarbon bearing formation. In some embodiments, a highly conductive fluid is injected into the hydrocarbon bearing formation. Moreover, when a plurality of first and second electrodes are placed throughout sections of the Earth's strata with discontinuities therein, the power output of the energy source harvested from the Earth can be greatly increased.

Terminology

The terms and phrases as indicated in quotation marks (" ") in this section are intended to have the meaning ascribed to them in this Terminology section, applied to them throughout this document, including in the claims, unless clearly indicated otherwise in context. Further, as applicable, the stated definitions are to apply, regardless of the word or phrase's case, to the singular and plural variations of the defined word or phrase.

The term "or" as used in this specification and the appended claims is not meant to be exclusive; rather the term is inclusive, meaning "either or both."

References in the specification to: "one embodiment"; "an embodiment"; "another embodiment"; "an alternative embodiment"; "one variation"; "a variation"; and similar phrases mean that a particular feature, structure, or characteristic described in connection with the embodiment or variation, is included in at least an embodiment or variation of the invention. The phrase "in one embodiment," "in one variation," or similar phrases, as used in various places in the specification, are not necessarily meant to refer to the same embodiment or the same variation.

The term "couple" or "coupled," as used in this specification and the appended claims, refers to either an indirect or direct connection between the identified elements, components or objects. Often the manner of the coupling will be related specifically to the manner in which the two coupled elements interact.

The term "hydrocarbon bearing formation," as used in this specification and the appended claims, refers to any type of formation including one or more hydrocarbon containing layers. Hydrocarbon bearing formations may also contain one or more non-hydrocarbon layers with the one or more hydrocarbon containing layers. The hydrocarbons contained in hydrocarbon bearing formations are typically, but not necessarily, oil and gas.

The term "overburden," as used in this specification and the appended claims, refers to any type of material that lies above a hydrocarbon bearing formation. Non-limiting examples of materials in the overburden include rock and soil.

An Exemplary Method of Providing Electricity using Earth Electromotive Force

FIG. **1** is a flow chart illustrating an exemplary method for producing electricity from Earth electromotive force. Method **100** generally describes producing electricity from Earth electromotive force where discontinuities in the Earth's strata enable redox chemical reactions creating variations in current and ion flow within the Earth's strata. However, some operations will be described according to an exemplary implementation of method **100** where a hydrocarbon formation and a water zone are used as discontinuities within the Earth's strata.

As shown in block **105**, a first electrode is placed within a first section of the Earth. The first section of the Earth can, and typically is, a hydrocarbon bearing formation. The hydrocarbon bearing formation is typically subsurface hundreds or thousands of feet below the Earth's surface. Modern drilling techniques can provide bores or wells as deep as 29,000 feet subsurface to reach various hydrocarbon bearing formations. However, a bore or well is more typically in the range of 5,000-8,000 feet below the Earth's surface. The first electrode is electrically coupled to a first terminal (block **105**). As can be deduced, electrically coupling the first electrode within a hydrocarbon bearing formation 5,000-8,000 feet below the Earth's surface can present a challenge. An elongated insulated conductor, typically a wire or cable, typically accomplishes the electrical coupling. However, other variations of the elongated insulated conductor are contemplated as will be described later in this specification.

Additionally, when the first electrode is placed into a hydrocarbon bearing formation, a highly conductive solution can be injected into the hydrocarbon bearing formation (block **110**). The highly conductive solution can comprise any suitable fluid. Typically, but not necessarily, the solution acts as an electrolyte in which ions made readily flow. In one variation, the highly conductive solution is salt water comprising sulfuring acid. The percentage of sulfuric acid can vary depending on the specific implementation, but is typically between 5-20%. Similarly, the concentration of salt in the water of the highly conductive solution is typically 20% or greater. Moreover, a powder of conductive metal may be added to and suspended in the highly conductive solution. For instance, a powder of zinc can be used to increase oxidation reactions thereby increasing the number of electrons available to the anode.

Next, as shown in block **115**, a second electrode is placed within a second section of the Earth. The second section of the Earth can, and typically is, a water zone. The second electrode can be placed in or proximal the water zone. Water zones include, but are not limited to, surface water zone or groundwater zone. Surface water zones include lakes (man-made or natural), rivers and streams, whereas groundwater zones include unconfined and confined aquifers. Moreover, it is often advantageous to electrically couple the second electrode to a metal casing of a shallow well bore, particularly if the metal casing is proximal or within a water zone such as a groundwater zone. Metal casings of the shallow well typically comprise the first section of an oil and gas well from the Earth's surface to a few hundred feet into the overburden.

With both the first and second electrodes properly placed and installed, an input voltage (typically very small at approximately less than 2 Volts) will be present at the first and second terminals. The input voltage can be measured to determine whether it is within a desired operating range. Hence, the input voltage at the first and second terminal can be adjusted (block **120**). In some implementations of method **100**, it is desirable to adjust the input voltage to approximately 900 mVolts prior for an effective boost converter stage.

The input voltage can be adjusted in any number of ways. For example, the first electrode can be moved up or down in the hydrocarbon bearing formation. In some implementations, the first electrode can be moved horizontally through the hydrogen bearing formation as some wells have horizontal well portions extending approximately 2,000 feet. Additionally, the second electrode can be moved closer or further from the water zone. Moreover, the size of either or both of the first and second electrodes can be increased or decreased. Also, the resistance of the elongated insulated conductor to the first terminal can be increased, but such a modification may not be desirable in some implementations as it would increase power loss prior to the boost converter stage.

Next, as shown in block **125**, the first and second terminals are electrically coupled to a boost converter assembly. Essentially, the boost convertor assembly comprises electronic circuitry to boost the unusable low input direct current (DC) voltage, typically lower than 1 Volt, to a more workable or desirable higher DC voltage, typically between 3-5 Volts. Additional DC-DC converters can boost the voltage to an output voltage of approximately 12-15 Volts.

As next described in block **130**, the operation of converting the output voltage of the boost converter assembly into a voltage suitable for commercial use is performed. Alternating current (AC) voltage is generally desired for commercial application. Typically, the output voltage is fed into a DC-AC inverter, which converts the approximately 12-15 Volts DC into an suitable AC power source of the required frequency and voltage (e.g., 60 Hertz 110-120 Volts AC).

It is to be appreciated that method **100** and variations thereof can be performed where the first and second section of the Earth are other than a hydrogen bearing formation and a water zone. The first and second sections can be areas of the Earth where discontinuities resulting from redox chemical reactions create variations in current flow between the first and second sections of the Earth such as, but not limited to, a geothermal brine formation, a geothermal hot water formation, a geothermal steam formation, a basaltic dyke, and a granite formation.

Embodiments of an Apparatus for Providing Electricity using Earth Electromotive Force

An embodiment of an apparatus for providing electricity using Earth electromotive force is illustrated in FIG. **2**. Apparatus **200** comprises a first electrode **210**, a first extended conductor **215**, a first terminal **230**, a second electrode **220**, a second conductor **225**, a second terminal **240**, and a boost converter assembly **250**. Apparatus **200** typically also comprises a DC-AC inverter assembly **260** having an AC output **270**.

Still referring to FIG. **2**, an oil and gas well **309** comprises a metal casing **322** of a shallow well bore at the Earth's surface. The oil and gas well **309** continues through an overburden **301** and into a hydrocarbon bearing formation **303**. As illustrated within the hydrocarbon bearing formation **303**, the oil and gas well **303** can have horizontal portions. Additionally, a groundwater zone **312** is shown running through a portion of the metal casing **322**.

Typically, but not necessarily, the first electrode **210** is an anode in an embodiment. As illustrated, the first electrode **210** is placed within the hydrocarbon bearing formation **303**. The hydrocarbons contained within the hydrocarbon bearing formation **303** have an excess supply of electrons. Also as previously described, the highly conductive solution can be added to the hydrocarbon bearing formation **303** to mix with the hydrocarbons thereby increasing conductivity and creating an electrolyte solution. The hydrocarbons are oxidized and lose electrons which are accumulated by the first electrode **210** acting as the anode. The first electrode **210** comprises material adapted to gain electrons such as, but not limited to zinc. Moreover, the first electrode **210** can be an elongated rod, typically metallic, between 1-2 inches in diameter and 50-100 feet long. However, it is to be appreciated that the first electrode can vary substantially between implementations and can comprise a number of different shapes and materials.

The first electrode **210** is connected and electrically coupled to a first extended conductor **215**. The first extended conductor **215** is typically insulated and of low resistance. Moreover, the first extended conductor **215** is electrically coupled to the first terminal **230**. The first extended conductor **215** can be an insulated wire or cable. However, given the extensive depth of the oil and gas well **309**, alternative first extended conductors can be utilized. For example, the first extended conductor **215** can be an elongated non-conductive tube comprising a highly conductive solution therein to establish conductivity between the first electrode **210** and the first terminal **230**.

Typically, but not necessarily, the second electrode **220** is a cathode in an embodiment. Still referring to FIG. **2**, the second electrode **220** is connected and electrically coupled to the metal casing **322** of the shallow well bore. Further, the metal casing **322** is in contact with a water zone, specifically the groundwater zone **312**. Water molecules and materials/chemicals in the overburden **301** in contact with the second electrode **220** can gain electrons (naturally having a lack of electrons) thereby creating a reduction reaction. Hence, the water molecules and materials/chemicals in the overburden **301** adopt electrons from the second electrode **220** acting as a cathode. The second electrode **220** comprises material adapted to lose electrons such as, but not limited to copper. The second electrode **220** is electrically coupled to the second terminal **240** through the second conductor **225**. It is pertinent to note that other embodiments comprise utilizing natural Earth currents associated with discontinuities in otherwise homogeneous Earth strata differently than as described above.

Importantly to apparatus **200**, the boost converter assembly **250** receives an input voltage from the first and second terminals **230** & **240** and converts the input voltage to an output voltage higher than the input voltage. The electronic circuitry of the boost converter assembly **250** boosts the unusable low voltages from the first and second terminals **230** & **240** to a more workable higher voltage. The low input DC voltage, typically lower than 1 Volt, can be boosted to a more workable higher DC voltage, typically between 3-5 Volts. Additional DC-DC converters can boost the voltage to an output voltage of approximately 12-15 Volts.

Still referring to FIG. **2**, the DC-AC inverter assembly **260** receives the DC voltage from the output of the boost converter assembly **250**. The DC-AC inverter assembly **260** converts the DC voltage (approximately 12-15 Volts DC) from the output of the boost converter assembly **250** into the AC output **270**. The AC output **270** output voltage from the DC-AC inverter assembly **260** comprises a suitable AC power source such as, but not limited to, a 60 Hertz 110-120 Volts AC output. Additionally, the boost converter assembly **250** and DC-AC inverter assembly **260**, as well as other electronic components of the apparatus **200** can be contained within a weatherproof but **290** proximal the metal casing **322** of the shallow well bore and oil and gas well **309**.

FIG. **3** is a schematic diagram for an exemplary boost converter circuit of an apparatus for producing electricity from Earth electromotive force according to an embodiment of the invention. Boost converter circuit comprises terminals for receiving a DC input voltage (V in). Referring momentarily back to FIG. **2**, the input voltage from the first and second terminals **230** & **240** may be received by one or more boost converter circuits. In one embodiment, the boost converter circuit (FIG. **3**) comprises a first capacitor C**1** having a value of 4.7 μF, an first inductor L**1** having a value of 4.7 μH, a first resistor having a value of 1.02 Mega Ohms, a second resistor having a value of 604 kilo Ohms, second capacitor having a value of 10 μF, and a DC-DC converter **300**. The DC-DC converter **300** is a synchronous, fixed frequency, step-up DC-DC converter contained within an integrated chip. Additionally, the boost converter circuit has a DC output voltage (V out). Again referring momentarily back to FIG. **2**, the output voltage and terminals from the boost converter assembly **250** illustrated into DC-AC inverter assembly **260** may be the DC output voltage(s) of one or more boost converter circuits. One or more boost converter circuits in a parallel array along with associated wiring and electrical components comprise an embodiment of the boost converter assembly **250**.

It is to be appreciated that the use of the solid state electronics in the one or more boost converter circuits enables the small voltage potential created from discontinuities between the two sections of the Earth's strata to be converted into a voltage suitable for commercial use.

FIG. **4** is an overhead perspective view of a plurality of electrodes from the apparatus creating an electrical system for producing electricity from Earth electromotive force according to an embodiment of the invention. An embodiment of the electrical system for producing electricity using Earth electromotive force comprises a plurality of first electrodes **210***a*, **210***b*, **210***c*, **210***d*, **210***e*, & **210***f*, a plurality of second electrodes **220***a*, **220***b*, **220***c*, **220***d*, **220***e*, & **220***f* and a multi-circuit boost converter assembly **255**.

In one embodiment, each first electrode **210***a*, **210***b*, **210***c*, **210***d*, **210***e*, & **210***f* is an anode and electrically coupled to a negative terminal through an extended conductor adapter to allow each first electrode **210***a*, **210***b*, **210***c*, **210***d*, **210***e*, & **210***f* to be placed within the hydrocarbon bearing formation **303**. Each second electrode **220***a*, **220***b*, **220***c*, **220***d*, **220***e*, & **220***f* is a cathode and electrically coupled to a positive terminal through a conductor to various areas. As illustrated, second electrodes **210***a*, **220***d*, **220***e*, & **220***f* are connected and electrically coupled to their metal casings **322***a*, **322***d*, **322***e*, & **322***f* some of which are in contact with groundwater zone **312**, whereas second electrodes **210***b* & **210***c* are placed in a lake **314**.

Still referring to FIG. **4**, the multi-circuit boost converter assembly **255** is very similar to the aforementioned boost converter assembly except that is adapted to receive each negative terminal from the plurality of first electrodes **210***a*, **210***b*, **210***c*, **210***d*, **210***e*, & **210***f*, and each positive terminal from the plurality of second electrodes **220***a*, **220***b*, **220***c*, **220***d*, **220***e*, & **220***f* into a boost converter circuit (FIG. **3**). The multi-circuit boost converter assembly **255** then converts an input voltage from each boost converter circuit to an output voltage higher than the input voltage and combines the output voltage from each boost converter circuit thereby providing a higher power output. Additionally, the output voltage can be converted to the AC output **270** suitable for commercial use by converting it with the DC-AC inverter assembly **260**.

It is pertinent to note that may variations of the electrical system exist. For instance, each of the plurality of second electrodes may be coupled to a single metal casing. Moreover, tens or hundreds of first and second electrodes can exist in a large oil field significantly increasing to power source of the electrical systems for producing electricity from Earth electromotive force. For example, using 100 boost converter circuits in the multi-circuit boost converter assembly can produce approximately 50 watts output at 3.3 Volts DC.

Alternate Embodiments and Variations

The various embodiments and variations thereof illustrated in the accompanying figures and/or described above are merely exemplary and are not meant to limit the scope of the invention. It is to be appreciated that numerous variations to the invention have been contemplated as would be obvious to one of ordinary skill in the art with the benefit of this disclosure. All variations of the invention that read upon the appended claims are intended and contemplated to be within the scope of the invention.

For example, the first electrode is typically an anode and the second electrode is typically a cathode of the apparatus. However, in some alternative embodiments, it is contemplated that the apparatus for generating power via Earth electromotive force may be used in a recharging battery configuration whereby the anode would be a positive terminal and the cathode would be a negative terminal. Hence, in such alternative embodiments, the cathode would send current back to an external generator.

I claim:

1. A method for producing electricity using Earth electromotive force, the method comprising:

placing a first electrode into a first section of the Earth, the first electrode being electrically coupled to a first terminal;

placing a second electrode into a second section of the Earth, the second electrode being electrically coupled to a second terminal; and

electrically coupling the first and second terminals to a boost converter assembly, the boost converter assembly adapted to convert an input voltage of approximately 2 volts or less from the first and second terminals to an output voltage of 3 to 5 volts, the boost converter assembly comprising a plurality of boost converter circuits operatively configured in parallel wherein each boost converter circuit comprises a synchronous step-up DC-DC converter contained within an integrated chip.

2. The method of claim **1**, wherein the first section of the Earth is a hydrocarbon bearing formation.

3. The method of claim **1**, wherein the second section of the Earth is a water zone.

4. The method of claim **2** further comprising,

injecting a highly conductive solution into the hydrocarbon bearing formation.

5. The method of claim **4**, wherein the highly conductive solution comprises salt water and sulfuric acid.

6. The method of claim **4**, wherein the highly conductive solution includes a powder of conductive metal.

7. The method of claim **1** further comprising,

adjusting the input voltage at the first and second terminals.

8. The method of claim **7**, wherein said adjusting the input voltage comprises moving the first and second electrodes a distance between each other.

9. The method of claim **7**, wherein said adjusting the input voltage comprises adjusting a voltage potential between the first and second electrodes until the voltage potential is approximately 900 mVolts.

10. The method of claim **1**, wherein said placing the first electrode comprises lowering the first electrode connected to a low resistance insulated conductor into a man-made bore on the Earth's surface to a distance greater than approximately 5,000 feet, and said placing the second electrode comprises connecting the second electrode to a metal casing of a shallow well bore.

11. The method of claim **1** further comprising,

converting the output voltage of the boost converter assembly into a standard AC voltage adapted for commercial use.

12. The method of claim **1**, wherein the first and second section of the Earth are in areas of the Earth where discontinuities resulting from redox chemical reactions create variations in current flow between the first and second sections of the Earth.

13. An apparatus for producing electricity using Earth electromotive force, the apparatus comprising:

a first electrode, the first electrode being an anode and installed in a first section of the Earth having an abundance of electrons relative to other parts of the Earth's strata;

a first extended conductor, the first extended conductor being insulated and electrically coupled to the first electrode;

a first terminal, the first terminal being electrically coupled to the first extended conductor;

a second electrode, the second electrode being a cathode and installed in a second section of the Earth having a lack of electrons relative to other parts of the Earth's strata;

a second terminal, the second terminal being electrically coupled to the second electrode; and

a boost converter assembly, the boost converter assembly adapted to convert an input voltage of approximately 2 volts or less from the first and second terminals to an output voltage of 3 to 5 volts, the boost converter assembly comprising a plurality of boost converter circuits operatively configured in parallel wherein each boost converter circuit comprises a synchronous step-up DC-DC converter contained within an integrated chip.

14. The apparatus of claim **13**, wherein (i) the first section of the Earth is a hydrocarbon bearing formation and (ii) the second section of the Earth is a water source.

15. The apparatus of claim **14**, wherein the water source is one of a lake and a groundwater flow area.

16. The apparatus of claim **13**, wherein the first electrode is an elongated conductive rod comprising copper and having a diameter between 1 and 2 inches and a length between 50 to 100 feet.

17. The apparatus of claim **13**, wherein the first extended conductor is a shielded wire having a length greater than 1,000 feet.

18. The apparatus of claim **13**, wherein the first extended conductor is an elongated non-conductive tube comprising a highly conductive solution therein.

19. An electrical system for producing electricity using Earth electromotive force, the electrical system comprising:

a plurality of first electrodes, each first electrode being an anode and electrically coupled to a negative terminal through an extended conductor adapted to allow each first electrode to be placed within a hydrocarbon bearing formation;

a plurality of second electrodes, each second electrode being a cathode and electrically coupled to a positive terminal through a conductor to a one of (1) a metal casing of a shallow well bore proximal a water zone and (2) a water zone; and

a multi-circuit boost converter assembly, the multi-circuit boost converter assembly comprising a plurality of boost converter circuits operatively configured in parallel, the multi-circuit boost converter assembly adapted to receive each negative terminal from the plurality of first electrodes and each positive terminal from the plurality of second electrodes, each boost converter circuit being conductively coupled with each other boost converter circuit in parallel and adapted to-convert an input voltage to an output voltage higher than the input voltage, each boost converter circuit comprising a synchronous step-up DC-DC converter contained within an integrated chip.

20. The electrical system of claim **19**, wherein the multi-circuit boost converter assembly further comprises,

a DC-DC converter assembly, the DC-DC converter assembly adapted to receive the higher power output from multi-circuit boost converter assembly and boost the output voltage to approximately 12 to 15 Volts, and

a DC-AC inverter assembly, DC-AC inverter assembly adapted to receive the output voltage to approximately 12 to 15 Volts from the DC-DC inverter assembly and convert the output voltage to a standard 120 Volts AC output.

UNITED STATES PATENT OFFICE.

EMIL JAHR, OF BERLIN, GERMANY.

METHOD OF UTILIZING ELECTRICAL EARTH-CURRENTS.

SPECIFICATION forming part of Letters Patent No. 690,151, dated December 31, 1901.

Application filed July 24, 1900. Serial No. 24,680. (No specimens.)

To all whom it may concern:

Be it known that I, EMIL JAHR, a subject of the King of Prussia, German Emperor, residing at Berlin, in the Kingdom of Prussia and German Empire, have invented certain new and useful Improvements in Methods of Utilizing Electrical Earth-Currents, (for which I have applied for patents in England, No. 9,971, dated May 30, 1900; in France, No. 289,156, dated June 2, 1900; in Belgium, No. 118,752, dated June 2, 1900; in Germany, dated May 26, 1900, and in Russia, dated June 5, 1900,) of which the following is a specification.

It is known that continuous electric currents flow through the solid and liquid portions of the earth's crust. Lamont (*Der Erdstrom und der Zusammenhang desselben mit dem Erdmagnetismus*, Leipsic, 1862) showed the existence of such currents by thrusting two metal plates at a certain distance from each other into the ground in the direction of the magnetic or astronomical meridian and connecting them above the ground by means of a wire including a galvanometer. The stronger currents of this kind have been shown to flow from south to north. Later observations (Weinstein, *Electrotechnische Zeitschrift*, 1898, p. 794) show that this so-called "earth-current" possesses a considerable uniformity of current strength and pressure. From the fact that this earth-current flows from south to north it may be concluded that its pressure will increase if starting from a given point in the south the distance between this and the northern point is increased, provided the connecting-lead be of little resistance. Notwithstanding that these facts have been known the earth-current has never been utilized, because in order to obtain a sufficient current the distance between the north and south points must be so great that the cost of an installation is prohibitive. I have discovered that the south to north direction of the earth-current is maintained only when the plates are of the same metal. When zinc is used for the southern plate and iron or carbon for the northern one, the current flows through the lead connecting them from north to south. All the common metals behave relatively similarly—that is, the current flows always from that plate whose position in the ordinary electrical potential series is near the negative end, (palladium.) I have also discovered that the current produced is of highest tension when the two metals are most widely separated from each other in the electrical potential series and that which is nearer to the positive end (zinc) of this series is thrust into earth or water at the more northerly point, while that which is nearer the negative end (palladium) of the series is thrust into earth or water at the southerly point. In such an arrangement the metals are not appreciably chemically corroded, even when they are in earth saturated with water, and are connected together by lead for a long time.

My invention relates, therefore, to a method for utilizing the earth-current, consisting in thrusting into the earth or water on the earth two electrodes, of which the one has a position north of the other and is of a material nearer to the positive end (zinc) of the electrical potential series than is the material of the other electrode and connecting the two above ground by a lead. It is advantageous that the northerly more electropositive electrode should be thrust more deeply into the earth or water than the southerly electrode, for then the current is stronger. The best result as to strength of current and pressure is obtained when this difference in depth is such that a line joining the two electrodes is in the direction of the magnetic dip. The best effect, therefore, is obtained when these conditions are combined—namely, when the two electrodes are approximately in the magnetic meridian and are of materials widely separated in the electrical potential series and the northerly and more electropositive electrode is buried at a greater depth than that at which the southerly electrode is buried and that a line joining them has the inclination of the magnetic dip. The current can be tapped from the lead joining the electrodes and utilized in any well-known manner.

What I claim, and desire to secure by Letters Patent of the United States, is—

1. A method of utilizing electrical earth-currents consisting in placing electrodes occupying different positions in the electrical potential series into the earth or water so that the electrode which is nearer the negative end of the series is at the more southerly point,

while the electrode which is nearer to the positive is at the more northerly point, and connecting the two electrodes together by a lead, the northern electrode being inserted deeper into the earth or water than the southern one, substantially as described.

2. A method of utilizing electrical earth-currents consisting in placing electrodes occupying different positions in the electrical potential series into the earth or water so that the electrode which is nearer the negative end of the series is at the more southerly point, while the electrode which is nearer to the positive is at the more northerly point, and connecting the two electrodes together by a lead, the insertion of the electrodes into the earth or water at such heights that a line connecting the same is situated in the direction from north to south, and also in the direction of the magnetic dip, substantially as described.

In testimony whereof I have hereunto set my hand in the presence of two witnesses.

EMIL JAHR.

EARTH BATTERY

DESCRIPTION

1. Field of the Invention

This invention pertains to earth batteries or electric wells and, more particularly, to a battery in which one electrode is a veined material located in the earth.

2. Background Art

Batteries which convert the chemical energy contained in their active materials directly into electrical energy by means of an oxidation-reduction electrochemical reaction are well-known in the art. Such batteries, in their most basic sense, include a pair of spaced apart electrodes and an electrolyte in the space between the electrodes. During the electrochemical reaction electrons are transferred from one electrode to the other and produce an electrical current when an external circuit is connected between the electrodes.

The electrode which gives up electrons during the reaction, and is oxidized in the process, is referred to as the anode. The other electrode, which is capable of accepting electrons and is an oxidizing material for the overall process, is referred to as the cathode. The electrolyte, generally an aqueous solution, provides the necessary internal ionic conductivity for the flow of electrons released at the anode. The electrolyte may also be a solid material.

The anode, cathode and the electrolyte may be made of a variety of materials, as is well known in the art. The only requirement for the anode and cathode is that one material must give up electrons at a faster rate than the other material, and thereby acquire a positive charge with respect to the other material. In one common battery arrangement, one electrode is made of carbon or copper, the other electrode is made of zinc and the electrolyte is sulphuric acid (H_2SO_4).

Various arrangements of these batteries, and the various combinations of materials which may be used for the electrodes and the electrolyte is discussed in Fink, *Standard Handbook for Electrical Engineers,* Eleventh Ed. 1978, pages 11-92 to 11-141, and is incorporated herein by reference.

It is also known in the art to use the earth as an electrolyte in a battery. Typically, two spaced electrodes are buried in the ground, and the ground, by itself or moistened with a chemical, functions as the electrolyte. See U.S. Pat. Nos. 155,209; 160,152; 182,802; 211,322; 329,724; 495,582; and 728,381. In the process disclosed in U.S. Pat. No. 3,278,335, an oil bearing formation forms a portion of an electrolyte and electrical energy is produced through the growth of bacteria in the formation. However, in each of these prior art patents, the electrodes are the typical zinc, carbon or copper plates or rods which are inserted into the earth, and the earth is used solely as an electrolyte.

It is an object of the present invention to provide a battery in which a portion of the earth is one electrode thereof.

It is a further object of the present invention to provide a battery in which one electrode is a veined material in the earth.

Another object of the present invention is to provide such a battery which is capable of generating electricity as well as capable of storing electrical energy.

It is yet a further object of the present invention to utilize such a battery in the mining of veined materials located in the earth.

SUMMARY OF THE INVENTION

Therefore, I have invented an electric battery which includes a first and second spaced electrode and an electrolyte in the space between the electrodes and in contact therewith, in which the first of the electrodes is a veined material located in the earth. In one embodiment, the second electrode is disposed in a hole which extends from the surface of the earth into the first electrode and is electrically connected to the surface of the earth, an electrolyte is disposed in the hole and in contact with the electrodes, and the first electrode is electrically connected to the surface of the earth. The battery may also include a casing disposed within the hole and surrounding the second electrode, such that the casing contains the electrolyte and permits contact of the electrolyte only with the first electrode but not with the surrounding earth. The first electrode is electrically connected to the earth's surface by way of one or more cables anchored thereto and located either within the hole or outside of the hole. The gases generated during the battery operation may be recovered and used as desired.

The first electrode is preferably a veined material located in the earth and may be a seam or vein of coal, graphite, magnetite, nickeline, sphalerite, arsenic, siderite, gold, silver, or copper.

I have also invented a method of mining metals located in the earth using the earth battery of the present invention. The method includes the steps of drilling a hole from the earth's surface into the metal to be mined, placing an electrolyte in the hole and in contact with the metal, positioning a recovery electrode within the hole and at least partially immersed in the electrolyte, making electrical contact with the metal, passing an electric current through the metal, electrolyte and recovery electrode such that the metal will be deposited on the recovery electrode, and removing the deposited metal from the recovery electrode.

I have also invented a method of drilling holes in the earth using the present invention. The method includes the steps of predrilling a small hole into the earth for a desired distance, placing a quantity of acid into the small hole such that the acid will seep into and soften the area around the small hole, and then drilling a hole through the area softened by the acid. The acid may be neutralized prior to the final drilling step.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1** is a partial cross section taken through the earth and through one embodiment of an earth battery in accordance with the present invention;

FIG. **2** is a perspective view of one embodiment of the second electrode;

FIG. **3** is a cross section of the bottom portion of one embodiment of the casing;

FIG. **4** is a cross section taken through the earth showing several alternative arrangements of the earth battery;

FIG. **5** is a cross section taken through the earth showing one embodiment of a gas recovery mechanism for the earth battery; and

FIG. **6** is a partial cross section taken through the earth showing one embodiment of a metal recovery apparatus in accordance with the present invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

An earth battery in accordance with the present invention is shown, partially in cross section, in FIG. **1**. The earth battery includes a first electrode **10** which is a veined material located within the earth **12**. A second electrode **14** is disposed within a hole **16** which extends from the surface **18** of the earth **12** and into the first electrode **10**. The second electrode **14** is electrically connected to the surface **18** of the earth **12** via cable **20**. An electrolyte **22** is disposed in the hole **16**, is in contact with the first electrode **10** and the second electrode **14**, and fills the space in the hole **16** therebetween. The electrolyte **22** is shown in FIG. **1** as a fluid, but it is to be understood that a solid electrolyte may also be utilized.

The earth battery shown in FIG. **1** also includes a casing **24** disposed within the hole **16**, adjacent the earth **12** and the first electrode **10** and surrounding the second electrode **14**. The casing **24** is preferably a hollow tube made of plastic or other insulating material and is adapted to prevent the electrolyte **22** from seeping out into the surrounding earth **12**. As shown in FIG. **1**, the casing extends from the earth's surface **18** to the bottom **26** of the hole **16**, but does not cover said bottom **26**. The casing **24** includes a plurality of openings **28** in the area where the casing is adjacent the first electrode **10**. These openings **28** permit the electrolyte **22** to contact and flow into the first electrode **10** but not into the surrounding earth **12**. The hole **16** and the casing **24** are preferably of circular cross section.

The second electrode **14** may be constructed in a variety of shapes. As shown in FIG. **1**, the second electrode **14** includes inner and outer cylindrical sleeves **30**, **32** mounted to a top plate **34**. A plurality of openings **36** through the sleeves **30**, **32** permit the electrolyte **22** to flow completely around all the surfaces of the second electrode **14**. In order to prevent the second electrode from touching the first electrode **10** or the casing **24**, and thereby shorting out the entire battery, insulating spacers **38** may be mounted on the sides or on the bottom of the second electrode **14**.

The first electrode **10** is electrically connected to the surface **18** of the earth **12** by means of a cable which extends into the earth and is physically anchored to the first electrode. As shown in FIG. **1**, cable **40** may be located within hole **16** and anchored to the bottom **26** of the hole by a spike **42** or the like. Alternatively, cable **44** may be located outside of hole **16** in a smaller hole **46** which passes into the first electrode **10**. Cable **44** is similarly anchored with spike **42**. A plurality of cables, spaced around or within the hole **16**, may also be used.

The electrolyte **22** will seep into and cause stress fractures **48** in the first electrode **10**. Cable **44** located outside of hole **16** is preferably anchored within the extent of the electrolyte **22** seepage. Over a period of time, the area of electrolyte seepage, and hence the effective size of the first electrode **10** in the battery, will slowly increase. It can be appreciated that the earth battery of the present invention can be permitted to grow as large as desired by allowing the electrolyte **22** to continue to seep into the first electrode **10**. The casing **24** is preferably sealed at the top by a lid **50** or the like. The rate of seepage of the electrolyte **22** into the first electrode may be regulated by a vacuum pump **52** connected to the inside of the casing **24**.

Various gases will be generated by the earth battery, both from the electrochemical reaction involved in the battery itself and the gases released from the first electrode **10** as the stress fractures **48** are formed. For example, if the first electrode **10** is a seam of coal, methane will be released, and if the second electrode is made of zinc and the electrolyte is sulphuric acid, oxygen and hydrogen will be generated during the electrochemical reaction of the battery. The casing lid **50** may include a pressure relief valve **54** to release these generated gases built up in the casing **24** when the pressure exceeds a predetermined value.

The earth battery described above operates in the exact same manner as a conventional battery and generates electrical energy from the electrochemical reaction of the electrodes and the electrolyte. The first electrode **10** is selected to be a veined material located in the earth and may include seams or layers of such materials as coal, graphite, magnetite, nickeline, sphalerite, arsenic, siderite, gold, silver and copper. The second electrode is selected from a material suitable for use with the particular veined material used as is well known in the art. A suitable electrolyte is selected to function with the electrodes chosen as is well known in the art.

In a preferred embodiment, a seam of coal is used as the first electrode, the second electrode is made of zinc, and sulphuric acid is used as the electrolyte. As an alternative, pickling acid, which is usually a waste by-product of a metal manufacturing plant, can be utilized as the electrolyte. Furthermore, a solid electrolyte, such as ammonium chloride (NH_4Cl) or zinc chloride ($ZnCl$) may be used. The use of an acidic electrolyte should not cause any environmental problems if the seam of coal, or other veined material, is located beneath the surrounding water table level. If pollution of the water table is of concern, an alkaline electrolyte, such as potassium hydroxide, may be used.

The earth battery described above may be used as a source of electrical energy at a variety of locations which have underground veins of suitable electrode material. The earth battery has the advantages that it is located primarily underground and out of the way, the functioning portions remain at a constant temperature, and the battery has the potential of growing to a rather large size. The battery of the present invention may be used as an electrical energy source, but may also be used to store electrical energy from a variety of sources such as solar cells, windmills, lightning, or the excess capacity from electrical utility plants.

An alternate embodiment of a second electrode **56** is shown in FIG. **2** and includes four rectangular plates **58** joined together along one edge to form an X-shaped structure. While only four plates **58** are shown in FIG. **2**, more or fewer plates may be utilized as desired. Second electrode **56** also includes a plurality of glass wheels **60**, each of which are mounted to the plates **58** by a bracket **62**. The glass wheels **60** are insulating and function to support and space second electrode **56** from the casing and the first electrode in a similar manner to the spacers **38** discussed above in connection with FIG. **1**.

An alternate arrangement for the casing is shown in FIG. **3**. Casing **64** shown in FIG. **3** is similar to casing **24** discussed above but further includes a bottom casing plate **66** which seals casing **64** and prevents the electrolyte from flowing downwardly. Openings **68** in casing **64** vary in size inversely with distance of each opening from the surface of the earth. The smallest opening is located nearest the bottom plate 66 and openings 68 gradually increase in size as the distance from the bottom plate increases. Since the pressure of the electrolyte fluid increases toward the bottom plate 66 from the weight of the fluid above, the rate of flow of the electrolyte through openings 68 and into the first electrode will remain constant.

A plurality of sharp protrusions 70 are located along the inner surface of casing 64 near openings 68 and on the bottom plate 66. When the earth battery of the present invention is no longer in use, it may be desirable to neutralize the acidic electrolyte liquid used. Baking soda, or any other acid neutralizing substance, may be placed into a glass or other breakable container and dropped into the casing. The breakable container will strike the sharp protrusions 70, break apart, and release the acid neutralizing substance into the electrolyte.

The earth battery of the present invention may utilize more than one veined material in the earth as electrodes and the materials may be the same or may be different from each other. In the configuration shown in FIG. 4, hole 72 passes from the earth's surface 74 through three veins of material, referred to as first electrode 76, first electrode 78 and first electrode 80. Casing 82 is disposed within hole 72 and extends to the top of first electrode 80. Openings 84 extend through casing 82 into first electrode 78 and openings 86 extend through casing 82 into first electrode 78. Second electrode 88 is disposed within casing 82 adjacent first electrode 76 and is connected to the earth's surface 74 via cable 89. Second electrode 90 is disposed within casing 82 adjacent both first electrode 78 and first electrode 80 and is connected to the earth's surface 74 via cable 91. As shown in FIG. 4, second electrode 90 is a single electrode which reacts electrochemically with both first electrode 78 and first electrode 80.

In the arrangement shown in FIG. 4, first electrode 76 is a negative material with respect to both first electrode 78 and first electrode 80. To prevent a shorting out of the earth battery, the interior of casing 82 is divided by a plug 92. In this manner, one earth battery is formed by first electrode 76, second electrode 88, and electrolyte 94, and a second, separate earth battery is formed by first electrode 78, first electrode 80, second electrode 90, and electrolyte 96. To replenish the supply of electrolyte 96, a pipe 98 extends from the earth's surface 74 through the plug 92.

Since hole 72 passes completely through first electrode 76 and first electrode 78, electrical connection between these electrodes and the earth's surface 74 cannot be made within hole 72. Cables 100 and 102 extend down and are attached to first electrode 76. While only two cables 100 and 102 are shown, it is to be understood that fewer or more cables may be attached to one such electrode. As shown in FIG. 4, first electrode 76 is exposed to the earth's surface, such as on a hill, and may be electrically contacted directly by cable 104 without the necessity of passing through the earth. First electrode 78 is electrically connected to the earth's surface by cable 106 and first electrode 80 is electrically connected to the earth's surface by cable 108. To avoid short circuits, the cables should not electrically contact the other veins of material through which they pass. Cable 106 is shown surrounded by heavy insulation 110 in the vicinity of first electrode 76. Cable 108 is shown physically spaced from first electrode 76 and surrounded by heavy insulation 112 in the vicinity of first electrode 78. Ideally, the entire length of each cable would be encased in an insulating material, except where electrical contact is made at the ends.

The relative electrical potential of each electrode shown in FIG. 4 is shown as being either positive or negative. The various electrodes could be operated as separate batteries, or could be connected in parallel or in series as is desired.

As an example of the arrangement shown in FIG. 4, first electrodes 78 and 80 could each be a seam of coal, which is considered to be a relatively positive material. Second electrode 90 may be made of zinc, a negative material when compared with coal. First electrode 76 may be a seam of magnetite (Fe_3S_4), nickeline (NiAs), or sphalerite (ZnS), each considered to be a negative material. Second electrode 88 may be made of carbon, a positive material when compared with the magnetite, nickeline or sphalerite. The particular arrangement used will be dictated solely by the various veined materials actually encountered within the earth.

An arrangement of an earth battery of the present invention which includes apparatus for collecting the gases generated during battery operation is shown in FIG. 5. The earth battery includes hole 114, passing through first electrode 116, and casing 118 which extends adjacent hole 114 as described above. Second electrode 120 is identical to the second electrode 14 shown in FIG. 1, except that it is turned upside down, and is electrically connected to the earth's surface 122 by cable 124. Electrolyte 126 is located in hole 114 between first electrode 116 and second electrode 120.

A funnel-shaped trap 128 is disposed above second electrode 120 to collect the gases generated therein. The trap 128 is connected to pipe 130 which carries the gas through valve 132 and then out of casing 118. Sleeve 134 is disposed within and spaced from casing 118 and terminates near the bottom of hole 114 in an inwardly directed, cone-shaped deflector 136. Deflector 136 is open to allow electrolyte 126 to flow between the interior and exterior of sleeve 134. Gases which are either generated by or are released from first electrode 116 are directed by deflector 136 into the space 138 between sleeve 134 and casing 118, and then out of casing 118 through valve 140.

If valves 132 and 140 were open, the gases generated would continuously escape. If valves 132 and 140 were closed, the pressure of the generated gases would increase, and eventually force electrolyte 126 up into the area between pipe 130 and sleeve 134, as is shown in FIG. 5. When the valves are opened, electrolyte 126 will drop back down to its original level and aid in expelling the generated gases.

The particular gases generated will depend on the exact materials involved. If the first electrode were coal, the second electrode zinc, and the electrolyte sulphuric acid, then oxygen would be generated at the second electrode, hydrogen would be generated at the first electrode, and methane would be released from the first electrode due to the fracturing of the coal from the electrolyte. The recovered gases could be used as is or could be burned to generate electric energy.

The earth battery of this invention can also be easily used to recover metals located in the earth. If a metal, such as gold, copper, or silver, is used as the first electrode, and a direct current is passed through the battery, the metal will be removed from the first electrode and plated onto the second electrode. By withdrawing the second electrode from the battery and removing the plated metal, the mining operation is completed.

Any of the earth battery arrangements discussed above could be utilized in the mining of such a metal. FIG. **6** shows an arrangement particularly adapted for mining a vein of metal. Hole **142** extends into the vein of metal **144** to be mined, casing **146** extends down to the top of the vein of metal, and electrolyte **148** is deposited in hole **142**. A recovery electrode **150** is placed into hole **142** and is at least partially immersed in electrolyte **148**. The recovery electrode **150** is connected to a direct current power source **152** by cable **154**.

The recovery electrode **150** shown in FIG. **6** is cup-shaped, open at the top, and includes a plurality of openings **156** passing therethrough. The outside of the recovery electrode **150** and the surface of openings **156** are covered with insulation **158**. Only the inner surface of the recovery electrode **150** is in contact with electrolyte **148**, and will be plated with the metal **144**.

To make electrical connection between the power source **152** and the vein of metal **144**, hole **160** is passed through the vein of metal, a liquid, electrically conductive material **162** is poured into hole **160**, and cable **164** is connected between the power source **152** and material **162**, preferably before liquid material **162** has solidified. By passing a direct current through the vein of metal **144**, electrolyte **148** and recovery electrode **150**, the metal will be plated on the recovery electrode as is known in the art.

The plated metal may be recovered by withdrawing the recovery electrode **150** from hole **142** and thereafter removing the metal. Alternatively, the metal could be removed with the recovery electrode **150** in place within hole **142**. Shown in FIG. **6** is a threaded auger **166** which is as wide as the inner width of the recovery electrode. The auger **166** may be rotated via shaft **168** and lowered into the recovery electrode **150** to thereby scrape off any metal plated thereon. The metal will then be floating in electrolyte **148** in small pieces. By removing electrolyte **148** via pump **170** through an outlet pipe **172**, the metal may be recovered by passing electrolyte **148** through a filter **174**. The filtered electrolyte may then be returned to the battery via an inlet pipe **176**.

This method can be used to recover natural veined metals located in the earth or metals buried in the earth such as gold bars, coins, or the like, which are otherwise inaccessible to conventional mining techniques. This method is particularly useful for mining paper thin seams of gold which cannot be economically mined using conventional mining techniques.

When the earth battery is no longer in use and the casing, second electrode, and other materials are removed from the hole, the ground surrounding the hole will be relatively soft due to the action of the acidic electrolyte. If a larger hole were desired, such as to reach oil deposits beneath the vein of material previously used in the earth battery, such drilling could be accomplished relatively early because the ground is already softened. This method of drilling may be useful in passing a large hole through a particularly hard rock formation. By merely drilling a small hole through the rock formation, pouring in a quantity of an acid solution, and letting the rock be softened by the acid, a larger hole may be easily drilled through the formation. It may be desirable to neutralize the acid remaining in the rock before the final drilling step. This may be done by pouring in an acid neutralizing solution, such as a baking soda solution.

Having described presently the preferred embodiments of this invention, it is to be understood that it may be otherwise embodied within the scope of the appended claims.

I claim:

1. In an electric battery including a pair of spaced electrodes and an electrolyte in the space between the electrodes and in contact therewith, the improvement comprising: one of said electrodes being a solid veined material located in the earth.

2. The battery of claim **1** wherein the veined material is selected from the group consisting of coal, graphite, magnetite, nickeline, sphalerite, arsenic, siderite, gold, silver, or copper.

3. The battery of claim **1** wherein the veined material is a seam of coal.

4. An earth battery comprising:

(a) a first electrode which is a solid veined material located in the earth;

(b) a second electrode electrically connected to the surface of the earth and disposed in a hole which extends from the surface of the earth into the first electrode;

(c) an electrolyte disposed in said hole and in contact with said first and second electrodes, and

(d) means for electrically connecting said first electrode to the surface of the earth.

5. The earth battery of claim **4** further including a casing disposed within the hole and surrounding the second electrode, wherein said casing contains the electrolyte and permits contact of the electrolyte with the first electrode but not with the surrounding earth.

6. The earth battery of claim **5** wherein the casing is a plastic tube which includes a plurality of openings in the area where the tube is adjacent the first electrode.

7. The earth battery of claim **6** wherein the electrolyte is fluid and wherein the openings vary in size inversely with their distance from the surface of the earth, such that the flow of electrolyte into the first electrode is at a uniform rate.

8. The earth battery of claim **4** wherein the means for electrically connecting the first electrode to the surface of the earth is a cable anchored to the first electrode.

9. The earth battery of claim **8** wherein the cable is anchored to the first electrode inside of said hole.

10. The earth battery of claim **8** wherein the cable is anchored to the first electrode outside of said hole.

11. The earth battery of claim **4** wherein the means for electrically connecting the first electrode to the surface of the earth is a plurality of cables anchored to the first electrode.

12. The earth battery of claim **11** wherein said plurality of cables are located outside of said hole.

13. The earth battery of claim **4** wherein the first electrode further includes one or more additional and separate veins of material located in the earth.

14. The earth battery of claim **4** further including means for recovering the gases generated during use of the battery.

15. The earth battery of claim **14** wherein the means for recovering gases includes a funnel-shaped trap located above the second electrode to collect the gases generated by the second electrode and wherein the means for recovering gases further includes a sleeve disposed within but narrower than the hole and adapted to direct the gases released by the first electrode into the space between the hole and the sleeve.

16. The earth battery of claim **4** further including a regulating means for controlling the flow of electrolyte into the first electrode.

17. The earth battery of claim **16** wherein the regulating means is a vacuum pump.

18. The earth battery of claim **4** wherein the first electrode is a vein of material selected from the group consisting of coal, graphite magnetite, nickeline, sphalerite, arsenic, siderite, gold, silver, or copper.

19. The earth battery of claim **18** wherein the first electrode is a seam of coal.

20. An earth battery comprising:

(a) a vein of coal located in the earth;

(b) an electrode disposed in a hole which extends through the vein of coal;

(c) a liquid electrolyte located in the space between the coal and the electrode;

(d) a casing disposed within the hole and surrounding the electrode, said casing directing the liquid electrolyte into the coal; and

(e) an electric cable anchored to the coal and extending to the earth's surface.

21. The earth battery of claim **20** wherein the electrode disposed in the hole is made of zinc and the electrolyte is an acid solution.

UNITED STATES PATENT OFFICE.

WILLIAM D. SNOW, OF BROOKLYN, NEW YORK.

IMPROVEMENT IN EARTH-BATTERIES FOR GENERATING ELECTRICITY.

Specification forming part of Letters Patent No. **155,209**, dated September 22, 1874; application filed June 6, 1874.

To all whom it may concern:

Be it known that I, WILLIAM D. SNOW, of Brooklyn, in the State of New York, have invented a certain Improvement in Earth-Batteries for Electro-Magnetic Alarms, &c.; and I do hereby declare the following to be a full and correct description of the same, reference being had to the accompanying drawing, which represents a series of electro-magnetic signaling or alarm apparatus placed in a house and operated by a current derived from an earth-battery, as hereinafter more fully set forth.

The object of my invention is to avoid the employment of artificial electric batteries for the purposes of house-signaling, fire and burglar alarms, and for the operation of other circuits.

In the common systems employed for these purposes a local or house battery is employed, requiring to be kept in working order by the occupants of the building in which it is placed, who are usually entirely ignorant of its structure and uses; or else the street line of wires is carried into the house, and thus subjected to all the contingencies to which the house itself is liable.

I obviate the trouble, annoyance, and danger to public safety incident to the systems referred to, by employing the current from an earth-battery without the intervention of any cups or vessels containing acids or other agents for the decomposition of zinc or other metals, commonly called a "battery." This I effect by making use of an earth-battery formed by burying the electrodes in the earth under the house at the depth of permanent moisture, so that the action of the dampness of the earth upon the plates will develop a sufficient permanent current for the required purposes. From these buried plates I run a telegraphic circuit in the house to connect with thermostats, signaling apparatus, fire and other alarms, annunciators, gas-lighters, or repeaters, according to the nature of the use to which the electric current is to be applied.

Some attempts have been made to use earth-batteries for various purposes. Such earth-batteries were made by simply burying a single set of elements in the earth, and proved of little or no practical value, on account of the very feeble intensity of the current generated. I have discovered, however, that if a series of elements be used in the earth, coupled together so as to form an earth-battery of any required size, this objection is obviated, and a constant current of considerable intensity is obtained, capable of operating steadily quite an amount of apparatus.

In the drawing, A and B mark two series of electrodes, which may be of zinc and carbon, as marked C and Z, buried in the earth under the house in which the circuit is to be used, the wire *d* being a connection between the dissimilar elements of the two series; C D, the wires for conducting the current, which may be made to complete the circuit by passing through E, an automatic thermostat; F, a repeater, connected with the street-wires J J; G, an annunciator; H, a fire-annihilator; or I, a signal-writing-bar apparatus, either one or more of these, each operated by the current in any of the usual modes.

What I claim is—

1. The improved earth-battery, consisting of a series of elements buried in the earth and connected together to form a battery, substantially as and for the purposes set forth.

2. The combination of two or more electric currents or circuits, when one of these is a current derived from an earth-battery, substantially as described, and is employed to operate the other or others.

The above specification of my said invention signed and witnessed at Washington this 30th day of May, A. D. 1874.

(57) **ABSTRACT**

A system for generating electricity from the geomagnetic field and rotation of the earth is presented. The earth rotates through the geomagnetic field to form a potential difference between first and second terrestrial charged bodies. The first and second charged bodies are spaced apart in a direction substantially normal to the earth's surface. The system comprises an electrical load, a first current path, and a second current path. The electrical load has a supply input and a ground output. The first current path is coupled to the first charged body and to the supply input of the electrical load, for supplying the potential difference to the electrical load. The second current path is coupled to the ground output of the electrical load and to the second charged body. As a result of this arrangement, an electric current related to the potential difference is generated in the electrical load.

FIG. 18

GENERATING ELECTRICITY FROM THE EARTH

BACKGROUND OF THE INVENTION

[0001] 1. Field of Invention

[0002] The present invention relates generally to renewable electrical energy sources, and more particularly to apparatus and methods for generating electricity from the earth's magnetic field and rotation.

[0003] 2. Background Art

[0004] The concepts of electromagnetic induction, Faraday's law, Faraday's disk, and the Lorentz force on charges are all well-known. These concepts have been applied to the earth, which is modeled as a large conductive sphere rotating through its own magnetic field ("geomagnetic field"). In this regard, the earth has been compared to a Faraday disk or homopolar generator. See, for example: W. M. Elsasser, The Earth as a Dynamo, Scientific American, Inc., Vol. 198, Issue 5, May 1, 1958, p. 44, 45; and C. R. Carrigan and D. Gubbins, The Source of the Earth's Magnetic Field, Scientific American, Inc., Vol. 240, Issue 2, Feb. 1, 1979, p. 118, 199-20. In making this comparison, the assumption has been carried over that the electricity to be obtained from the earth is from electromagnetic induction. Laboring under this assumption, it has been asserted that electricity from the geomagnetic field is not practicably retrievable, because the electricity gathering circuit would have to be stationary relative to the rotating earth (i.e., have a stationary frame of reference). This assertion is apparently based on a theory that the currents induced in the Faraday disk (or earth) and in the circuit employed to retrieve the electricity, would cancel each other out if both were moving through the magnetic field. Another theory is that a static electric field is created in the Faraday disk (or earth) that neutralizes the induced electric field, resulting in a zero voltage reading in the rotational frame of reference.

[0005] Further to this point, U.S. Patent App. Pub. No. 2004/0027022 (Feb. 12, 2004) to Weir, states that no voltage is generated by a Faraday type homopolar dynamo in the rotational reference frame of the dynamo (Weir, Par. [0010]). Weir even attempted to measure such voltage by mounting a voltmeter onto the rotating disk and connecting one probe to a shaft rotating the disk and the other probe to the rim of the disk. Weir states that the voltmeter read zero volts when the disk was rotating. (Weir Par. [0011].) No details are given regarding the sensitivity of the voltmeter or the test setup. In a book by Thomas Valone, Ph.D, P.E., entitled The Homopolar Handbook, published by Integrity Research Institute, Washington, D.C., 3rd Edition, October 2001 ("Valone I"), it is stated that an electrostatic field (created in response to the Lorentz force) neutralizes the electric field induced on the Faraday disk ("effective electric field"), and thus no voltage can be detected with a meter that rotates with the disk (Valone I, p. 7 & FIG. **8**). Valone discusses his voltage measurement on page 24 and again at page 63. He indicates that his voltmeter was set to indicate a voltage reading only if the voltage was greater than 15 millivolts. Thus, the sensitivity of Valone's experiment may have been limited to 15 millivolts, presumably because the induced electric field (obtained in the stationary reference frame) was expected to be 100 millivolts (see Valone I, p. 63).

[0006] Valone reminds us that Michael Faraday, in 1831, compared his Faraday disk to the earth and the earth's rotation through its magnetic field. Valone states that Faraday, thinking that an induced voltage could be measured on his rotating disk, attempted to measure a like voltage in the earth (i.e., in rivers and streams) and apparently was unsuccessful. (Valone I, p. 61.) Valone characterizes Faraday's thinking as a mistake. Valone presumably mentions Faraday's unsuccessful attempt at measuring voltage in the earth as support for his position that a voltage cannot be measured in the rotating reference frame. In an earlier paper, entitled "The Homopolar Generator: Tesla's Contribution," Proceedings of the International Tesla Symposium, January 1986 ("Valone II"), Valone specifically stated that "we can't draw power from the earth's Homopolar generator while rotating with it." (Valone II, p. 273.)

[0007] Notwithstanding the view that a voltage is unobtainable in the rotating frame of reference in a Faraday system, proposals were made in the 1980s for a space shuttle to drag a tether (an insulated conductor) through space across the geomagnetic field to generate electric power onboard the shuttle. Current and a voltage potential difference would be induced on the tether's conductor as it passed through the magnetic field lines of the earth. The current return path (or ground path) would be the charged plasma medium of the ionosphere, which would exist between the outer wall of the space shuttle and the distal end of the tether (or an outer wall of a satellite attached to the distal end). A load (e.g., electronic equipment) inside the space shuttle would be connected between the proximal end of the tether and the outer wall of the shuttle (i.e., the return or ground path). A tether experiment was actually performed on a space shuttle mission in 1996, according to a NASA article (www.istp.gsfc.nasa.gov/Education/wtether.html). The voltage generated on the tether was 3500 volts, apparently measured in the rotational frame of reference. It is suggested that the voltage may have been measured at the distal end of the tether with instruments aboard a satellite connected to the distal end. The voltage level at the load inside the shuttle is not mentioned. In this experiment, the voltage applied to the intended load (equipment aboard the shuttle) was supplied by the tether's conductor and the return or ground path for the load was, according to NASA, the ionospheric plasma between the shuttle and the satellite.

[0008] An alternative design to the above-mentioned space tether was purportedly developed by or for the U.S. Army in 1988 and patented in U.S. Pat. No. 4,923,151 (1990) to Roberts. Roberts discloses a coaxial tether (Roberts, FIGS. **2** and **3**) about 12.5 miles long, comprising an outer conductor **20**, a magnetic shield conductor **26**, and a center conductor **30**. Outer conductor **20** is electrically connected at one end to a satellite **12** and at the other end to an orbiting shuttle **10** (Roberts, FIGS. **1** and **2**). Center conductor **30** is magnetically shielded from the geomagnetic field by conductor **26**, which is made of a high permeability metal such as soft iron. Center conductor **30** is electrically insulated from conductors **20** and **26** by insulation **28**. Center conductor **30** is also electrically connected at one end to satellite **12** (at point **32**) and at the other end to a load **36** inside shuttle **10** (through a switch **34**). Load **36** is grounded via a return current path including the outer surface **40** of shuttle **10**, conductor **20**, and the outer surface **22** of satellite **12**. The tether passes through the geomagnetic field at an orientation substantially normal to the earth and its magnetic field lines. As a result, a potential difference ("PD") is produced between shuttle **10** and satellite **12**. Conductor **26** magnetically shields center conductor **30**, so no induced current flows in conductor **30**. Conductor **30** assumes the charge potential of satellite **12** and applies the potential difference PD across load **36** (once switch **34** is closed), causing current to flow in load **36**. Conductor **20** replaces the ionosphere as the return current path, purportedly making the circuit more stable. Thus, conductor **20** functions both as a Faraday conductor (i.e., a conductor on which currents are induced from a magnetic field) and as the return current path. In this case, the Faraday conductor (conductor **20**) does not function as the supply current path (conductor **30** does). In the previously discussed space tether design, the Faraday conductor (i.e., the tether's only conductor) did serve as the supply current path and did not serve as the return current path (the ionosphere).

[0009] For over 40 years, the inventor named herein has been working on an idea for generating electricity from the earth's rotation and magnetic field. The argument that electricity is generated in the earth is supported by some natural phenomena, including: the decreasing speed of the earth's rotation, the continued molten state of the earth's interior, volcanic and geyser activity, the earth's magnetic field, and lightning. The earth uses its primary kinetic energy, which originally started its rotation, to electrically charge itself by electromagnetic induction. Electric energy flowing toward the center of the earth is transformed into magnetic and heat energy, sustaining the earth's magnetic field and the molten state of the earth's interior. The balance in pressure between the surface and the molten interior is maintained through the loss of heat energy at the surface by heat radiation and volcanic and geyser activity. As a result of the work performed by the earth, and possibly because of a counter electromagnetic force (Lenz's law), the earth's kinetic energy is decreasing and its rotation is slowing.

[0010] The inventor herein began thinking about his idea while observing thunderstorms. In 1979, during one of his experiments, he was struck by a branch of lightning and luckily survived with no significant injury. He decided to continue experimentation, but in a safe manner. Upon arrival to the United States, the inventor herein applied for a grant and technical support from the National Institute of Standards and Technology (NIST) on May 18, 1995. His application was assigned an Evaluation Request (ER) Number 32042 and a Control Number 015351. The application was ultimately rejected with an explanation that the magnetic field rotates with the earth and thus currents could not be induced in a conductor installed on the earth. NIST's rejection of the idea dissuaded the inventor herein from pursuing the idea further, until recently when the inventor started thinking about the Faraday disk and "Faraday's paradox."

[0011] Faraday's paradox is the non-intuitive result that electric currents are induced in the Faraday disk even when the magnet rotates with the disk. It is non-intuitive because many would assume that the magnetic field rotates with the rotating magnet and disk, in which case currents would not be induced in the disk. Faraday conducted three tests to investigate this phenomenon. First, he rotated the disk and kept the magnet stationary and observed a current induced in the disk. Second, he kept the disk stationary and rotated the magnet and observed no induced current in the disk. Third, he rotated the disk and magnet together and observed a current in the disk. From these tests, Faraday concluded that the magnetic field remained stationary when the magnet was rotated around its own magnetic axis. Similarly, the earth (representing a rotating disk and magnet) should produced a stationary magnetic field through which the earth rotates, thus inducing generally radial electric currents in the earth and on conductors substantially aligned with the earth's radius. Since Faraday, there has been a long-standing debate and experimentation about Faraday's paradox and whether or not the magnetic field rotates with the magnet. For example, see Valone I, pp. 2-4 and 37. Notwithstanding the theoretical debate and investigation, it is believed that Faraday was correct and that currents are induced by the geomagnetic field in the earth, in the surrounding atmosphere, and in conductors appropriately located on the earth and in the atmosphere.

[0012] Nikola Tesla disclosed a conductor extending into the atmosphere and normal to the earth's surface in U.S. Pat. No. 685,957 (Tesla). Rather than seek to induce currents in the conductor from the geomagnetic field, Tesla sought to collect radiant energy (or particles charged by radiant energy) primarily from the sun. Tesla somehow suspended a conductive plate P and connected it to the distal end of the conductor (Tesla, FIG. **1**). The proximal end of the conductor was connected to a capacitor C. The other end of capacitor C was connected to a secondary conductor, which is, in turn, connected to a conductive plate P' grounded in the earth. Plate P was the collector of radiant energy charged particles. The charge from plate P charged capacitor C. A voltage threshold device (d) and a load R are connected across capacitor C to form a circuit. Device (d) closes the circuit when the charge on capacitor C exceeds a predetermined voltage, causing the voltage to be applied to load R. In this patent, Tesla does not seek to obtain the potential difference between two "terrestrial charged bodies" (hereinafter defined).

[0013] Herein, the term "terrestrial" is used in a broad sense, to include the whole or any part of the earth and its surrounding atmosphere, including but not limited to: the earth's inner and outer cores, mantle, crust, any layer or level thereof, and its surface; all bodies of water; air; clouds; ice; vegetation; minerals and other resources such as oil; rocks including basalt; or any other composition or thing of the earth and its atmosphere. As used herein, the term "terrestrial charged body" (or its plural form) means a terrestrial body, region, layer, zone, other volume or area, any composition or thing, with or without specifically defined or fixed boundaries, having an electric charge represented by a voltage potential.

OBJECTS AND SUMMARY OF THE INVENTION

[0014] It is therefore an object of the present invention to overcome the problems and limitations associated with the prior art and to fulfill a long-felt but unsolved need for a renewable source of energy.

[0015] It is another object of the present invention to provide a clean and renewable source of electrical energy.

[0016] It is a further object of the present invention to generate electricity from the earth's magnetic field and rotation.

[0017] It is yet another object of the present invention to provide a reliable source of electricity from the earth's magnetic field and rotation.

[0018] It is yet a further object of the present invention to provide a source of electricity from the earth's magnetic field and rotation that can be easily implemented.

[0019] It is still another object of the present invention to provide a source of electricity from the earth's magnetic field and rotation that can be implemented at a low-cost.

[0020] These and other objects are attained in accordance with the present invention, wherein there is provided a system for generating electricity from the geomagnetic field and rotation of the earth. The earth rotates through the geomagnetic field to form a potential difference between first and second terrestrial charged bodies. The first and second terrestrial charged bodies are spaced apart in a direction substantially normal to the earth's surface. The system comprises an electrical load, an electrically insulated first current path, and a second current path. The electrical load has a supply input and a ground output. The first current path is coupled to the first terrestrial charged body and to the supply input of the electrical load, for supplying the potential difference to the electrical load. The second current path is coupled to the ground output of the electrical load and to the second terrestrial charged body. As a result of this arrangement, an electric current related to the potential difference is generated in the electrical load.

[0021] In one particular embodiment, the first terrestrial charged body includes a first portion of the earth located below the earth's surface and the second terrestrial charged body includes a second portion of the earth located at or near the earth's surface. The earth contains an opening extending between the first and the second portions of the earth. In this embodiment, the first current path includes (i) an electrically insulated conductor extending at least partially through the opening and (ii) a conductive contact member coupled to the electrically insulated conductor for establishing electrical contact between the first portion of the earth and the electrically insulated conductor. In a more specific embodiment, the opening is a well bore or mine shaft, and the first portion of the earth includes a bottom of a well or mine. The electrically insulated conductor extends through the bore or mine shaft, and the conductive contact member establishes electrical contact between the bottom of the well or mine and the electrically insulated conductor.

[0022] In another embodiment, the first terrestrial charged body may be a portion of the earth at or near the surface of the earth, and the second terrestrial charged body may be a cloud above the surface of the earth. In yet another embodiment, the first and second terrestrial charged bodies may be first and second charged portions of the earth, respectively, where both portions are located at or near the surface of the earth. In this latter embodiment, the first portion of the earth is at a first elevation and the second portion of the earth is at a second and different elevation. For example, the first elevation may be at or near the bottom of a mountain or cliff and the second elevation may be at an elevated position on the mountain or cliff. In still another embodiment, first terrestrial charged body is a portion of the earth at the bottom of a body of water, such as the ocean, and the second terrestrial charged body is the water at or near the surface of the body of water.

[0023] In any of the embodiments, the electrical load may include a rechargeable energy source, including a rechargeable battery or battery pack and a charging circuit coupled to the rechargeable battery or pack. Alternatively, or in addition to batteries, the rechargeable energy source may include a charging capacitor or a bank of charging capacitors along with an appropriate charging circuit for the capacitor(s). The capacitor or capacitors may be ultracapacitors. The electrical load may further include an electric motor coupled to the rechargeable energy source. The electric motor may be a DC motor, which may be mechanically coupled to an AC generator. In operation, the DC motor would actuate the AC generator, resulting in the AC generator generating AC electric power. Alternatively, the electric load may include an inverter for converting DC electric power to AC electric power. In either case (AC generator or inverter), the AC electric power can be stepped up in voltage and applied to an electric power grid.

[0024] A method of generating electricity from the geomagnetic field and rotation of the earth is also within the scope of the present invention. As indicated earlier, the earth rotates through the geomagnetic field to form a potential difference between first and second terrestrial charged bodies. The first and second terrestrial charged bodies are spaced apart in a direction substantially normal to the earth's surface. The method comprises the steps of: (a) providing an electrically insulated first current path having first and second electrically exposed ends; (b) coupling the first end of the first current path to the first terrestrial charged body to establish electrical communication between the first current path and the first terrestrial charged body; (c) coupling the second end of the first current path to a supply input of an electrical load to supply the potential difference to the electrical load; (d) providing a second current path having first and second ends; (e) coupling the first end of the second current path to a ground output of the electrical load; and (f) coupling the second end of the second current path to the second terrestrial charged body to establish electrical communication between the electrical load and the second terrestrial charged body. As a result of these steps, an electric current related to the potential difference is generated in the electrical load.

BRIEF DESCRIPTION OF THE DRAWING

[0025] Further objects of the present invention will become apparent from the following description of the preferred embodiments, with reference to the accompanying drawing, in which:

[0026] FIG. **1** is a diagram of a test setup used to demonstrate the operation of a Faraday disk and the generation of electricity within the rotational frame of reference;

[0027] FIGS. **2** is a diagram of an experiment showing a rotating Faraday disk with a voltmeter having lead wires and test leads for measuring voltages at different points along the disk's radius;

[0028] FIG. **3** is a diagram of an experiment illustrating a battery analogy of the Faraday disk and the concept of short circuit (SC) current on the disk;

[0029] FIG. **4** is a diagram of a field experiment with one embodiment of the present invention, implemented in conjunction with a water well;

[0030] FIG. **5** is a diagram of the earth rotating through its magnetic field and showing (schematically) three terrestrial charged bodies spaced apart from each other in a direction normal to the earth's surface;

[0031] FIG. **6** is a diagram of the earth partially dissected to reveal a portion of a flat circular plane through the earth's equator, presented as an analogy of a Faraday disk;

[0032] FIG. **7** is a diagram of a first embodiment of the present invention, wherein the terrestrial charged bodies are separated portions of the earth;

[0033] FIG. **8** is a diagram of a second embodiment of the invention, which is an implementation utilizing a well;

[0034] FIG. **9** is a diagram of a third embodiment of the invention, which is an implementation utilizing a mine and a mine shaft;

[0035] FIG. **10** is a diagram of a fourth embodiment of the invention, which is an implementation utilizing a body of water, wherein one terrestrial charged body is the bottom of the body of water and another terrestrial charged body is a surface of the body of water;

[0036] FIG. **11** is a diagram of a fifth embodiment of the invention, which is an implementation utilizing different elevations of the earth's surface, such as associated with a mountain or cliff;

[0037] FIG. **12** is a diagram of a sixth embodiment of the invention, which is an implementation utilizing the atmosphere of the earth, wherein one terrestrial charged body is a cloud and another terrestrial charged body is a surface of the earth;

[0038] FIG. **13** is a diagram of a seventh embodiment of the invention, which is an implementation utilizing a well having a bore casing and an electrical load (which may include a submersible pump) is located at least partially within the bore casing;

[0039] FIG. **14** is a diagram of an eighth embodiment of the invention, which employs coaxial conductors to carryout the invention;

[0040] FIG. **15** is a cross-sectional view of the coaxial conductors of FIG. **14**, taken along line **15-15** in FIG. **14**;

[0041] FIG. **16** is a block diagram of one example of an electrical load of the present invention, which is a rechargeable energy source including a charging circuit and a charge storage device, such as a rechargeable battery(s) or storage capacitor(s);

[0042] FIG. **17** is a block diagram of another example of an electrical load of the invention, which includes a charging and control circuit, charge storage device, and an electric motor; and

[0043] FIG. **18** is a block diagram of a further example of an electrical load of the present invention, including a charging and control circuit, a charge storage device, and an inverter or AC generator with step-up transformer.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

[0044] Inspired by the book "The Homopolar Handbook" by Thomas Valone (Valone I), the named inventor built a Faraday disk to perform a few original experiments. A direct consequence of the experiments is the extraction and use of one part of the existing electrical energy of the earth. FIG. **1** illustrates a Faraday disk apparatus **10** built by the inventor herein. Apparatus **10** includes a frame **12** made of 2×6 wooden boards, connected together with screws. An axle **14** is made of a ⅝ inch diameter, 3-foot long steel threaded rod. Axle **14** has a sharpened lower end **14***a*, which rests on a steel plate **16**. Axle **14** is rotatably supported by two bearing assemblies **18***a* and **18***b*. Bearing assembly **18***a* is mounted in an upper cross member **12***a* of frame **12** and bearing assembly **18***b* is mounted in a bottom cross member **12***b* of frame **12**. A drill **20** is connected, via a chuck **22**, to a short rod **24**, which is, in turn, connected to one end of an insulator block **26**. The upper end of axle **14** is connected to the other end of insulator block **26**. Rod **24**, block **26** and axle **14** rotate together as a unit. The speed of drill **20** is manually controlled to control the rotational speed of axle **14**. Insulator **26** electrically isolates axle **14** from the drill to eliminate any chance of electric current from drill **20** finding its way into axle **14**.

[0045] As further shown in FIG. **1**, the actual Faraday disk comprises a 17-inch diameter round aluminum baking pan **28** and two 16-inch diameter (and ¼-inch thick) steel disks **30***a* and **30***b*. Pan **28** and disks **30***a*, **30***b* are fixed together and balanced on axle **14**, using washers and steel hex nuts threaded on axle **14**. Disk **30***a* is fixed in and against the bottom of pan **28** and disk **30***b* is fixed directly underneath and against pan **28** (collectively referred to as disk assembly **28'**). Axle **14** and disk assembly **28'** rotate together, almost like a spinning top. In order to reduce electrical resistance associate with axle **14** above disk assembly **28'**, a copper ring **32** is clamped to axle **14** and an insulated copper wire **34** is connected between ring **32** and disk assembly **28'**. Two spring-loaded graphite brush contacts **34***a* and **34***b* are installed. Brush contact **34***a* is adjacent to and in contact with copper ring **32** and brush contact **34***b* is adjacent to and in contact with the rim of disk assembly **28'**. Contact **34***a* and a lead wire **36***a* electrically connect ring **32** to one input of a digital voltmeter **38**. Contact **34***b* and a lead wire **36***b* electrically connect the rim of disk assembly **28'** to a second input of voltmeter **38**. Voltmeter **38** is mounted outside of frame **12** and is held stationary. Another digital voltmeter **40** is mounted on disk assembly **28'** and rotates with assembly **28'**. Voltmeter **40** is electrically connected, via a short lead wire **42***a*, to the rim of disk assembly **28'** and is electrically connected, via a longer lead wire **42***b*, to axle **14**. A digital camera **44** is fixed on axle **14** (just below insulator block **26**) to record the digitally displayed readings of voltmeter **40**.

[0046] Again referring to FIG. **1**, twenty-two cylindrical welding magnets, each five inches in diameter and each with a pull strength of 75 lbs, are arranged to form two magnetic cylinders **46***a* and **46***b* (11 magnets each). Cylinders **46***a* and **46***b* are separated from each other by disk assembly **28'**. Magnetic cylinders **46***a*, **46***b* are installed in a way that allows them to be held stationary or to be rotated with disk assembly **28'**. In a series of tests, axle **14** was rotated at a speed of about 200 RPM and voltmeter **38** measured and read a generated potential difference of about 300 millivolts. No difference in voltage generation was noted between tests where magnetic cylinders **46***a*, **46***b* were held stationary or rotated (Faraday's paradox). During the 200 RPM tests, voltmeter 40 read 1 to 3 millivolts, supporting the view that a voltage potential difference is generated and measurable on the rotating frame of reference. These tests are referred to collectively as "Experiment A." The difference in readings between voltmeter **38** and voltmeter **40** will be explained below.

[0047] Referring now to FIG. **2**, a diagram of a rotating disk experiment is shown. Disk assembly **28'** and voltmeter **38** are used in this experiment. Lead wires **36***a* and **36***b* of voltmeter **38** include test leads **48***a* and **48***b*, respectively. Leads **48***a*, **48***b* are placed on rotating disk assembly **28'** in a sliding engagement to establish dynamic electrical contact with assembly **28'**. As disk assembly **28'** was rotated, voltage measurements were taken at different points along the radius of the assembly (i.e., at different imaginary concentric circles on disk assembly **28'**). Voltmeter **38** measured the potential difference between the points of contact. The positive side of the potential difference is toward the center, as indicated in FIG. **2**, due to the Lorentz force pushing electrons radially out to the rim. The measured potential difference increased as the distance between the contact points increased. This experiment is referred to hereinafter as "Experiment B."

[0048] An understanding as to why there is a difference in electric potential measured by voltmeter **38** and voltmeter **40** (FIG. **1**) was gained in another experiment, illustrated in FIG. **3**. In this experiment, an attempt was made to model the electrodynamics on a rotating Faraday disk. This was done by applying a potential difference across disk assembly **28'** (between axle **14** and the rim), while disk assembly **28'** remained stationary (as did voltmeter **38**). This setup was intended to mimic the case where the voltmeter and disk are rotating in the same frame of reference. The potential difference was applied across disk assembly **28'** using a 6-volt battery **50**. This modeled the potential difference generated on a rotating disk by electromagnetic induction. Insulated copper wires **52***a* and **52***b* were connected to the terminals of battery **50** and to axle **14** and the rim of disk assembly **28'**, as shown in FIG. **3**. The positive side of battery **50** is connected at axle **14** and the negative side is connected at the rim to model the charge displacement due to induction. Lead wires **36***a,* **36***b* of voltmeter **38** were also connected to disk assembly **28'**, in the vicinity of the connections of wires **52***a,* **52***b,* respectively. The voltage (or potential difference) measured by voltmeter **38** was 50 millivolts. A reading of 6 volts would be expected in an open circuit measurement. On the other hand, a reading of 50 millivolts would suggest a near short circuit (considering the inherent resistance in disk assembly **28'**). Voltmeter **38** did measure a short circuit current, which is indicated in FIG. **3** by arrow SC. This experiment is referred to hereinafter as "Experiment C."

[0049] Based on Experiments A, B and C, it was concluded that the rotation of disk assembly **28'** in the magnetic field (created by magnetic cylinders **46***a,* **46***b*—FIG. **1**) caused the disk assembly to become charged and develop a potential difference in the radial direction. The potential difference increased as the distance between the center of disk assembly **28'** and a measurement point along the radius of assembly **28'** increased. This potential difference was created by the Lorentz force pushing electrons out to the rim, causing an induced current to flow radially outward. In response to the induced potential difference, electrons seek to establish equilibrium on the disk (as it is a conductor) and begin to flow in a direction opposite of the induced current. This opposite flow of electrons is referred to as the short circuit current and is indicated in FIG. **3** by arrow SC. It is believed that this short circuit current is flowing at all times on a rotating Faraday disk. This may be the reason why a voltage is measureable on the rotating frame of reference (voltmeter on the disk), albeit a smaller voltage than the induced voltage measured in the stationary frame of reference. A rotating Faraday disk (i.e., disk assembly **28'**) behaves like a battery (or multiple batteries connected in series) with one pole at the center of the disk (axle **14**) and the other pole at the rim. While rotation in the magnetic field causes the disk to be charged, a short circuit simultaneously occurs. The disk loses its charge immediately when it stops rotating. A Faraday disk (and thus disk assembly **28'**) can be thought of as comprising a number of imaginary annular rings, each behaving like a circular-shaped battery and the batteries are connected in series. Thus, the largest potential would occur at the rim, where all of the annular rings (batteries) of the disk are in series and in the circuit.

[0050] The concepts studied in the lab in Experiments A, B and C were then applied in the field, with respect to the earth's rotation and magnetic field. FIG. **4** illustrates an experiment that was conducted at two different drilled water wells, one 117 feet deep and the other 210 feet deep. The wells were drilled at construction sites of new homes in a suburban area near Utica, N.Y. At the time of the experiments, the wells were not in use. There were no electric power lines or transmitting antennas within a great distance around the construction sites. A copper pipe **54**, one-half inch in diameter and two feet long, was connected to an insulated copper wire **56**, to ensure a good connection with the earth at the bottom of the well. Pipe **54** and wire **56** were lowered to the bottom of each well. Pipe **54** made direct contact with the earth at the bottom of each well. The bottom of each well is considered a first charged body (defined above). Another one-half inch diameter and two-foot long copper pipe **58** was hammered into the ground at the surface, about 6 feet from the well. The surface and earth surrounding pipe **58** is considered a second charged body. A digital voltmeter **60** was used to measure the difference in electric potential between the bottom of the well and the surface of the ground (i.e., between the first and the second charged bodies). Voltmeter **60** has test lead wires **62** and **64**. Test lead wire **62** is connected to insulated wire **56** and test lead wire **64** is connected to copper pipe **58**. Steady measurements of **592** millivolts were obtained in the 117-foot well and 858 millivolts were obtained in the 210-foot well. Short circuit current between the surface and the bottom of the well was also measured with meter **60**. As the distance between the surface and bottom of the well increased, the difference in electric potential increased.

[0051] A variation of the setup in FIG. **4** was also tested at the 210-foot well (indicated in dash lines). The well includes a metal bore casing **66** that extends substantially down the well bore. The variation is that casing **66** was used as part of the circuit instead of copper pipe **58**. Test lead wire **64** was connected directly to casing **66**. The voltage measurements were consistent with those obtained in the original tests for the 210-foot well. It is believed that the use of casing **66** as part of the circuit, instead of a ground pipe (like pipe **58**), may yield more consistent voltage readings. The tests performed at both wells, as described in this and the previous paragraph, are collectively referred to hereinafter as "Experiment D." In the tests of Experiment D, wire **56** was an insulated 14-Gauge Stranded THHN Cable, Model No. 22955957, supplied by the Southwire Company, Carrollton, Ga., featuring conductors made of annealed (soft) copper, rated at 600 Volts, and insulated with tough, heat- and moisture-resistant PVC. Voltmeter **60** was a Mini Pocket MultiMeter, Model DM110, by Extech Instruments Corp., Nashua, N.H., with 0.1 millivolt DC voltage resolution and 0.01 milliamp DC current resolution. Another voltmeter was also used to re-confirm the readings. That meter was a Cen-Tech Seven Function Digital Multimeter, Model 98025, supplied by Harbor Freight Tools Co., Camarillo, Calif., with milliamp and millivolts resolutions.

[0052] The earth is an oblate spheroid with an equatorial radius of 6378.16 km. The earth and its surrounding atmosphere rotate within the earth's magnetic field (i.e., the geomagnetic field). The speed of a point at the earth's equator is about 463.8 m/sec. In the Utica, N.Y. area, where Experiment D was performed, the speed is about 300 m/sec. By comparison, the speed of sound is 340.29 m/sec. The earth's magnetic field is estimated to be about 0.35 to 0.65 gauss at the earth's surface. By comparison, a strong refrigerator magnet has a field strength of 100 gauss. The geomagnetic field is generally dipolar as it has two poles, the north and south magnetic poles, and the field lines resemble those of a dipolar magnet. FIG. **5** illustrates the geomagnetic field on one side of the earth's magnetic axis **70**. Generally, the earth can be considered a conductor having the following five parts: (1) the solid inner core, which is an excellent conductor; (2) the molten outer core, which is an excellent conductor; (3) the mantle, much of which is a good conductor; (4) the crust, which is a relatively good conductor; and (5) the atmosphere, which can be a good or poor conductor.

[0053] To help with the understanding of the results obtained in Experiment D and with the operation of the present invention, consider the following theory. (This theory should not be construed as defining or limiting the scope of the present invention in any way, and it should not affect the validity of the invention if proven to be incorrect. It is presented in the hope that it may aid in the understanding of the invention.) One should picture the earth and the surrounding (rotating) atmosphere as an endless number of concentric spheres, from the earth's center to the earth's surface, and from the earth's surface to the outer reaches of the surrounding, rotating atmosphere. FIG. **5** depicts two spheres associated directly with the earth itself. A sphere **72** represents any level or layer under the earth's surface between the center and the surface. For example, sphere **72** could be (generally) a junction between the earth's crust and its mantle, a junction between the earth's mantle and the outer core, or a particular layer within the earth's crust or mantle. A sphere **74** represents the earth's surface. Alternatively, one can picture the earth as an endless number of disks, with the largest diameter disk cutting through the equator (see FIG. **6**) and the smallest diameter disks approaching the poles.

[0054] As shown in FIG. **5**, the geomagnetic field (showing one side of the field) comprises a plurality of magnetic field lines **68** disposed generally in a dipolar arrangement about magnetic axis **70**. As the earth rotates through the geomagnetic field, it behaves similar to a rotating Faraday disk, in that electrons dislocate outward from the center to the surface. This causes a potential gradient to be established along the radius of the earth and into the atmosphere, with the positive side toward the center and the negative side toward the surface. A potential difference is measured between any two designated spheres of the earth and atmosphere (e.g., spheres **72** and **74** in FIG. **5**), and the potential difference increases with the spacing between the designated spheres. At the same time, electrons travel back toward the center of the earth as the electromagnetic system seeks equilibrium, and this causes a permanent short circuit current to flow in the earth's interior.

[0055] Continuing with the theory, induction also exists in the atmosphere, especially in the clouds. Clouds are connected to the earth's surface by air that is generally a poor conductor. Some short circuit current through dry air may exist, but a big difference in electric potential develops between clouds and the earth's surface. During storms, the air between the earth's surface and clouds, and between clouds at different levels (representing different spheres), become saturated with water and form columns that are relatively good conductors. An intense short circuit current occurs through such conductors. When the amount of current becomes so intense that the conductor cannot accept it any longer, because of its properties (air and water), it simply burns out. The flash and explosion (i.e., lightning and thunder) are results of the burning out of the overloaded conductor. Most likely, a similar event happened to NASA's tether experiment, when an almost 20 km long insulated wire burned out by an estimated 1 amp of current at 3500 volts (see NASA tether experiment article, www.istp.gsfc.nasa.gov/Education/wtether.html).

[0056] Further with the theory, the earth behaves like one huge battery (similar to Faraday's disk), constantly being charged by the rotation within its own magnetic field. One pole of the battery is at the earth's center and the other pole is at the earth's surface or at some designated point in the atmosphere. One can also imagine the earth as an endless number of sphere-shaped batteries connected in series. At the same time, a permanent short circuit in the earth exists, like the battery in Experiment C above.

[0057] It is not possible or practicable to obtain the electric potential between the center of the earth and its surface using Faraday's approach, because stationary brush contacts cannot be placed at the center and the surface (i.e., a stationary frame of reference for the collection circuit cannot be established). However, it is possible to obtain an electric potential from the short circuit current between different designated spheres reachable from the earth's surface (e.g., Experiment D).

[0058] Referring again to FIG. **5**, sphere **72** contains a designated terrestrial charged body **76** and sphere **74** (earth's surface) contains a designated terrestrial charged body **78**. A cloud **80** in the atmosphere **82** is also designated as a terrestrial charged body. Terrestrial charged bodies **76**, **78** and **80** are spaced apart from each other in a direction substantially normal to the earth's surface. An imaginary axis **84** represents the alignment of the charged bodies in a direction normal to the surface. Due to electromagnetic induction, a potential difference is formed between terrestrial charged bodies **76** and **78**, between charged bodies **76** and **80**, and between charged bodies **78** and **80**. A terrestrial charged body is that amount (e.g., area or volume) of earth, water, minerals, rocks, clouds, etc. sufficient to define, accumulate or hold a charge which can produce a measurable potential difference with another terrestrial charged body.

[0059] Referring to FIG. **6**, there is shown a model of the earth with a portion removed to reveal an imaginary plane or disk **86**. Disk **86** cuts through the equator. FIG. **6** illustrates an analogy between the earth's interior and a Faraday disk (see earlier discussion above). In this example, an interior section or region of the earth's crust or mantle serves as a first terrestrial charged body **88**, and the earth's surface serves as a second terrestrial charged body **90**. Compare FIG. **6** with FIG. **2**. The rotation of the earth through its magnetic field causes terrestrial bodies **88** and **90** to become charged and a potential difference to be form between them, as in Experiment B (FIG. **2**).

[0060] Referring now to FIG. **7**, a system **100** for generating electricity from the geomagnetic field and rotation of the earth is shown as a first embodiment of the present invention. As explained, a potential difference (PD) is formed between terrestrial charged bodies—here terrestrial charged bodies **102** and **104**. In this embodiment, body **102** is underground earth (e.g., rock, soil, and/or minerals, etc.) at the bottom of an opening or hole (man-made or natural) and body **104** is the surface soil of the earth. Charged bodies **102**, **104** are spaced apart in a direction normal to the earth's surface. System **100** comprises an electrical load **106** having an input **108** and an output **110**. A first insulated conductor **112** is coupled at one end to charged body **102** via a contact member **114** and is connected at its other end to load input **108**. Contact member **114** may be, e.g., a short (e.g., 2 ft long) piece of copper or aluminum pipe. Conductor **112** is insulated to avoid direct electrical contact with the earth, except for charged body **102**. Conductor **112** is soldered or otherwise electrically connected to contact member **114**. The other end of conductor **112** is either directly connected to load input **108** (as shown) or is coupled to input **108** via a jumper wire and/or a connector. In FIG. **7**, a first current path is defined between load **106** and body **102** by contact member **114** and conductor **112**. The first current path supplies the PD to load **106**. A second insulated conductor **116** is coupled at one end to charged body **104** via a contact member **118** and is connected at the other end to load output **110**. Contact member **118** may be the same type as contact member **114**. Conductor **116** may be the same type and model as conductor **112**. A second current path is defined between load **106** and body **104** by conductor **116** and contact member **118**. A return current path occurs between charged bodies **104**, **102** via the intervening earth. Thus, a complete electrical circuit is established from charged body **102**, contact member **114**, conductor **112**, load **106**, conductor **116**, contact member **118**, charged body **104**, and the return current path back to charged body **102**. An electric current related to the PD is generated in load **106**. Load **106** may comprise a charging circuit and a charge storage device, a motor, and/or an AC generator or inverter, as discussed later. Contact members **114**, **118** may be any form of electrical conductor, including but not limited to a plate, disk, sphere, cone, rod, cylinder (hollow or solid), or sharp pointed member or members.

[0061] Referring now to FIG. **8**, a system **200** for generating electricity from the geomagnetic field and rotation of the earth is shown as a second embodiment of the present invention. A potential difference PD is formed between spaced apart terrestrial charged bodies **202** and **204**. Body **202** is underground earth at the bottom of a well and body **204** is the surface soil of the earth. The well includes a drilled wellbore extending from the earth's surface to the well bottom. A metal casing **203** extends down into the bore. At the bottom of the well is a supply of water **205**. System **200** comprises an electrical load **206** having an input **208** and an output **210**. A first insulated conductor **212** is coupled at one end to charged body **202** via a contact member **214** and is connected at its other end to load input **208**. Contact member **214** may be submerged in water **205**. Conductor **212** is insulated to avoid direct electrical contact with metal casing **203** and the earth, except for charged body **202**. A first current path is defined between load **206** and body **202** by conductor **212** and contact member **214**. This current path supplies the PD to load **206**. A second insulated conductor **216** is coupled at one end to charged body **204** via a connection (e.g., a solder joint) **217** to casing **203**. Conductor **216** is connected at its other end to load output **210**. A second current path is defined between load **206** and body **204** by conductor **216**, connection **217** and casing **203**. A return current path occurs between charged bodies **204**, **202** via casing **203** and the earth (and/or water **205**). Thus, a complete electrical circuit is established from charged body **202**, contact member **214**, conductor **212**, load **206**, conductor **216**, connection **217**, casing **203**, charged body **204**, and the return current path back to charged body **202**. An electric current related to the PD is generated in load **206**. In this embodiment, it is preferred that the bottom of the well be at least **400** feet deep relative to the surface.

[0062] Referring now to FIG. **9**, a system **300** for generating electricity from the geomagnetic field and rotation of the earth is shown as a third embodiment of the present invention. A potential difference PD is formed between spaced apart terrestrial charged bodies **302** and **304**. In this embodiment, body **302** is underground earth at a bottom of a mine and body **304** is the surface soil of the earth. The mine contains a drilled or excavated opening or mineshaft extending from the earth's surface to the bottom. A metal frame **303** may be present in the shaft. System **300** comprises an electrical load **306** having an input **308** and an output **310**. A first insulated conductor **312** is coupled at one end to charged body **302** via a contact member **314** and is connected at its other end to load input **308**. Contact member **314** makes direct contact with the bottom of the mine and, in some cases, may slightly penetrate the bottom. Conductor **312** is insulated to avoid direct electrical contact with frame **303** and/or the earth (except for charged body **302**). A first current path is defined between load **306** and body **302** by conductor **312** and contact member **314**. The first current path supplies the PD to load **306**. A second insulated conductor **316** is coupled at one end to charged body **304** via a contact member **318** and is connected at its other end to load output **310**. Contact member **320** has been driven into the earth to make good electrical contact with body **304**. Alternatively, conductor **316** may be coupled to body **304** via a connection (e.g., a solder joint) **320** to metal frame **303** (if any). A second current path is defined between load **306** and body **304** by conductor **316** and contact member **318** (or by conductor **316**, connection **320** and frame **303**). A return current path occurs between charged bodies **304**, **302** via the earth or, alternatively, via frame **303** and the earth. Thus, a complete circuit is established from charged body **302**, contact member **314**, conductor **312**, load **306**, conductor **316**, contact member **318** (or connection **320** and frame **303**), charged body **304**, and the return current path back to charged body **302**. An electric current related to the PD is generated in load **306**.

[0063] Referring now to FIG. **10**, a system **400** for generating electricity from the geomagnetic field and rotation of the earth is shown as a fourth embodiment of the present invention. A potential difference PD is formed between spaced apart terrestrial charged bodies **402** and **404**. In this embodiment, charged body **402** is the bottom or bed of a body of water (e.g., the earth's crust, basalt, sand, clay, sediments or other settled materials, a change in salinity, etc.). Charge body **404** is the water at or near the surface of the body of water. The body of water is preferably a salt water system such as an ocean, sea, ocean bay, strait, estuary, lake, and the like. System **400** comprises an electrical load **406** having an input **408** and an output **410**. A first insulated conductor **412** is coupled at one end to charged body **402** via a contact member **414** and is connected at its other end to load input **408**. Contact member **414** makes direct contact with the bottom and, in some cases, may penetrate the bottom. Conductor **412** is insulated to avoid direct electrical contact with the body of water. A first current path is defined between load **406** and body **402** by conductor **412** and contact member **414**. The first current path supplies the PD to load **406**. A second insulated conductor **416** is coupled at one end to charged body **404** via a metal boat **418**, which serves as a contact member. Conductor **416** is connected at its other end to load output **410**. Conductor **416** is directly connected to boat **418**, as represented by the electrical ground symbol. An alternative contact member may be a thin metal (e.g., copper or aluminum) plate **418'**, which floats on the water. In the latter case, conductor **416** is directly connected to plate **418'**. A second current path is defined between load **406** and body **404** by conductor **416** and boat **418** (or by conductor **416** and plate **418'**). A return current path occurs between charged bodies **404**, **402** via the body of water. Thus, a complete circuit is established from charged body **402**, contact member **414**, conductor **412**, load **406**, conductor **416**, boat **418** or other contact member, charged body **404**, and the return current path back to charged body **402**. An electric current related to the PD is generated in load **406**.

[0064] Referring now to FIG. **11**, a system **500** for generating electricity from the geomagnetic field and rotation of the earth is shown as a fifth embodiment of the present invention. A potential difference PD is formed between spaced apart terrestrial charged bodies **502** and **504**. In this embodiment, both charged bodies **502**, **504** are portions of the earth at or near the earth's surface, but body **504** is at a higher elevation than body **502**. This may be the case, for example, at a mountain or cliff System **500** comprises an electrical load **506** having an input **508** and an output **510**. A first insulated conductor **512** is coupled at one end to charged body **502** via a contact member **514** and is connected at its other end to load input **508**. Contact member **514** is driven into the earth to establish good electrical contact with charged body **502**. Conductor **512** is insulated to avoid direct electrical contact with the earth. A first current path is defined between load **506** and body **502** by conductor **512** and contact member **514**. The first current path supplies the PD to load **506**. A second insulated conductor **516** is coupled at one end to charged body **504** via a contact member **518** and is connected at its other end to load output **510**. Member **518** has been driven into the earth to make good electrical contact with body **504**. A second current path is defined between load **506** and body **504** by conductor **516** and contact member **518**. A return current path occurs between charged bodies **502**, **504** via the intervening earth. Thus, a complete circuit is established from charged body **502**, contact member **514**, conductor **512**, load **506**, conductor **516**, contact member **518**, charged body **504**, and the return current path back to charged body **502**. An electric current related to the PD is generated in load **506**.

[0065] Referring now to FIG. **12**, a system **600** for generating electricity from the geomagnetic field and rotation of the earth is shown as a sixth embodiment of the present invention. A potential difference PD is formed between spaced apart terrestrial charged bodies **602** and **604**. In this embodiment, charged body **604** is a cloud or a stream of clouds passing overhead and charged body **602** is a portion of the earth at or near the earth's surface. A preferred location for system **600** is at a high elevation, such as a mountain top, where low lying clouds are a frequent occurrence. As air is generally a poor conductor, the flow of short circuit current between clouds and the earth's surface is very limited, resulting in the buildup of a huge difference in electrical potential between the clouds and the earth's surface. THIS EMBODIMENT IS VERY DANGEROUS DUE TO LIGHTNING STRIKES AND STATIC ELECTRICITY. ANYONE WHO BUILDS THIS EMBODIMENT, WHETHER AUTHORIZED BY THE INVENTOR HEREIN OR NOT, ASSUMES ALL RISK OF PERSONAL INJURY OR DEATH AND ASSUMES ALL LIABILITY TO OTHERS INJURED OR KILLED AS A RESULT OF THE CONSTRUCTION AND/OR OPERATION OF THIS EMBODIMENT.

[0066] Again referring to FIG. **12**, system **600** comprises an electrical load **606** having an input **608** and an output **610**. A first insulated conductor **612** is coupled at one end to charged body **602** via a contact member **614** and is connected at its other end to load input **608**. Contact member **614** has been driven into the earth to make good electrical contact with body **602**. A first current path is defined between load **606** and body **602** by conductor **612** and contact member **614**. The first current path supplies the PD to load **606**. A second insulated conductor **616** is coupled at one end to charged body **604** via a contact apparatus **618** and is connected at its other end to load output **610**. Apparatus **618** includes a non-conductive tower **618***a*, an upwardly extending metal bracket **618***b*, and a metal collector plate **618***c*. Tower **618***a* is preferably built from a non-conductive material such as, for example, wood, fiberglass, fiberglass reinforced plastic, and the like. Tower **618***a* may be supported by non-conductive guy wires such as Phyllistran guys or Polygon structural fiberglass guys. Alternatively, tower **618***a* may be electrically insulated from the ground using an electrically insulating barrier between the tower and the ground. Conductor **616** is electrically connected to metal bracket **618***b*. Conductor **616** is insulated to avoid electrical contact with the surrounding atmosphere. Bracket **618***b* and collector plate **618***c* establish electrical coupling with the electric charge in cloud **604**. Plate **618***c* is a metal sheet of metal, such as copper or aluminum. A second current path is defined between load **606** and body **604** by conductor **616**, metal bracket **618***b*, and collector plate **618***c*. A return current path occurs between charged bodies **604**, **602**, via the atmosphere or moisture or precipitation in the atmosphere. Thus, a complete circuit is established from charged body **602**, contact member **614**, conductor **612**, load **606**, conductor **616**, bracket **618***b*, collector plate **618***c*, charged cloud **604**, and the return current path back to charged body **602**. An electric current related to the PD is generated in load **606**.

[0067] As mentioned, the hazards of lightning are obviously a major concern in system **600**. Lightning protection schemes are not infallible and no representation is made herein that system **600** is safe from the hazards of lightning strikes or static electricity. In system **600**, a surge arrester device **620** is installed between load output **610** and ground (FIG. **12**). Device **620** is shown as a gas-filled surge arrester, but the preferred arrester is a spark gap rated for lightning strike voltages. Preferably, conductor **616** is a high voltage stranded single conductor cable, such as used to connect lightning rods to grounding rods, but covered with insulation having a high dielectric strength to withstand lightning strikes.

[0068] An alternative embodiment to system **600** (not shown) is to replace apparatus **618** with a hydrogen- or helium-filled balloon (e.g., a weather balloon). The balloon would have a conductor such as copper or aluminum foil wrapped around it or a metal plate or band mounted on it. In this embodiment, insulated conductor **616** would be electrically connected to the conductor on the balloon. This embodiment would otherwise be the same as system **600**. The warnings and disclaimers made above with respect to system **600** are equally applicable to this embodiment.

[0069] Referring now to FIG. **13**, a system **700** for generating electricity from the geomagnetic field and rotation of the earth is shown as a seventh embodiment of the present invention. This embodiment concerns a well and is fundamentally the same as the second embodiment, except here the electrical load is located down in the wellbore. A potential difference PD is formed between terrestrial charged bodies **702** and **704** (i.e., bottom of well and earth surface). The well includes a drilled bore and a metal casing **703** extending down into the bore. At the bottom of the well is a supply of water **705**. An electrical load **706** has an input **708** and an output **710**. A first insulated conductor **712** is coupled at one end to charged body **702** via a contact member **714** and is connected at its other end to load input **708**. A first current path is defined between load **706** and body **702** by conductor **712** and contact member **714**. The first current path supplies the PD to load **706**. A second insulated conductor **716** is coupled at one end to charged body **704** via an electrical connection (e.g., a solder joint) **717** to metal casing **703**. The other end of conductor **716** is connected to load output **710**. A second current path is defined between load **706** and body **704** by conductor **716**, connection **717** and casing **703**. A return current path occurs between charged bodies **704**, **702**, via casing **703** and the earth (and/or water **705**). Thus, a complete electrical circuit is established from charged body **702**, contact member **714**, conductor **712**, load **706**, conductor **716**, connection **717**, casing **703**, charged body **704**, and the return current path back to charged body **702**. An electric current related to the PD is generated in load **706**. In the case where casing **703** is not made of electrically conductive material, an alternative coupling arrangement with charged body **704** is: conductor **716** is connected to a contact member **718**, which is driven into the ground at the earth's surface.

[0070] Load **706** may contain a charge storage system and a wellbore submersible pump controlled by a control unit **720**. The charge storage system stores electricity generated by system **700** and supplies the stored electricity to the pump when called upon by control unit **720**. Control unit **720** communicates with the pump via a control cable **722**. Control unit **720** includes an auto-control function that controls the pump automatically. Unit **720** switches on the power to the pump by means of a pressure switch actuated in response to a pressure valve or by means of a float level switch actuated by a float. An example of a submersible pump powered by a renewable electrical energy source is disclosed in U.S. Pat. No. 7,837,450, which is incorporated herein by reference.

[0071] Referring now to FIGS. **14** and **15**, a system **800** is another embodiment of the present invention. This embodiment is characterized by a coaxial cable **801** installed between two spaced apart, substantially parallel, terrestrial charged bodies **802** and **804**. Cable **801** includes a copper (or copper-clad steel) center conductor **812** insulated by a dielectric insulating material **812***a*, such as cellular polyurethane, polyurethane foam or solid polyethylene. Cable **801** further includes an outer shield conductor **803**, which may be a woven braid of bare or tinned copper wires, a wrap of aluminum foil tape, a solid copper or aluminum tube, or a combination thereof. Shield conductor **803** may be insulated or left uninsulated. In FIGS. **14** and **15**, conductor **803** is insulated generally by a jacket **803***a* made of plastic, such as polyvinyl chloride (PVC). When cable **801** is installed, jacket **803***a* is preferably removed between charged bodies **802** and **804**, as shown in FIG. **14**. System **800** comprises an electrical load **806** having a supply input and a ground output made available at a threaded female coaxial connector **808**. Cable **801** has a finished proximal end with a threaded male coaxial connector **809**. Connector **809** is considered male because it has a stinger wire, which is to be inserted into connector **808**. The stinger wire is connected to or an extension of center conductor **812**. Connector **809** includes a threaded slip ring **809***a* for threading connector **809** onto connector **808**.

[0072] Once connectors **808** and **809** are connected together, center conductor **812** is in electrical contact with the supply input of load **806** and shield conductor **803** is in electrical contact with the ground output of load **806**. Center conductor **812** is electrically coupled to charged body **802** via a metal contact member **814**. Conductor **812** delivers the potential difference between charged bodies **802**, **804** to load **806**. Shield conductor **803** is electrically coupled to charged body **804** by direct contact as shown. Thus, the ground output of load **806** is electrically coupled to charged body **804**. Conductor **803** is also coupled to charged body **802** by direct contact as shown. Alternatively, conductor **803** may be in direct contact with a portion of the earth defined to be outside of charged body **802** (thus making indirect contact with body **802**). A return current path occurs between charged bodies **802**, **804** primarily through shield conductor **803**. Using conductor **803** as the return current path improves return path performance by making the path easier to implement and maintain, and it operates more predictably because it is not dependent on the variable properties and conditions of earth, water, atmospheric, and other natural or in situ return current paths. In system **800**, a complete electrical circuit is established from charged body **802**, contact member **814**, center conductor **812**, load **806** (via connectors **809**/**808**), shield conductor **803** (via connectors **808**/**809**), charged body **804**, and shield conductor **803** back to charged body **802**. An electric current related to the PD between charged bodies **802**, **804** is generated in load **806**.

[0073] As shown in FIG. **14**, an alternative or additional ground output **810** is provided in electrical load **806**. An insulated conductor **816** is connected to output **810** and to a contact member **818**. In this case, shield conductor **803** may be decoupled from the original ground output, for example, by operation of an automatic impedance sensing switch internal to load **806**. Optionally, both outputs (**810** and original output via **803**) may be in operation together. In connection with output **810**, the return current path remains primarily through shield conductor **803**. The complete electrical circuit is from charged body **802**, contact member **814**, center conductor **812**, load **806** (via connectors **809**/**808**), conductor **816**, contact member **818**, charged body **804**, and shield conductor **803** back to charged body **802**.

[0074] Referring now to FIG. **16**, there is shown one example of an electrical load **900** of the present invention. A supply input S and a ground output G of load **900** correspond to, for example, load input **108** and load output **110**, respectively (e.g., see FIG. **7**). The potential difference between a pair of terrestrial charged bodies, obtained in accordance with the present invention, is presented across terminals S and G of load **900**. The apparatus of the present invention that obtains this potential difference (examples of which are shown in FIGS. **7**-**14**) is referred to in FIGS. **16**-**18** as a geomagnetic voltage source. Load **900** includes a charging circuit **902** and a charge storage system **904**. The specifics of charging circuit **902** depend upon the type of charge storage system used. System **904** may be, for example, a rechargeable battery or series of batteries or a charging capacitor or bank of charging capacitors. A basic charging circuit for a rechargeable battery (or series of batteries) may be a positive going diode in series with a source resistor, and both in series with the rechargeable battery (or series of batteries). A basic charging circuit for a capacitor (or bank of capacitors in series) may be an inductor in series with the capacitor (or bank of capacitors). The latter circuit typically includes a switching element or elements to cause the geomagnetic voltage source to charge the inductor in a first switched state and to cause the charged inductor to charge the capacitor or capacitors in a second switched state. If capacitors are used for the charge storage elements, a preferred form of capacitor is the ultracapacitor. Ultracapacitors and their charging circuits are disclosed in the following references: M. S. W. Chan, K. T. Chau, and C. C. Chan, Effective Charging Method for Ultracapacitors, Journal of Asian Electric Vehicles, Vol. 3, No. 2, December 2006, pp. 771-76; and Maxwell Technologies Application Note, Document 1008981 Rev 1, December 2005, pp. 2-3. The disclosures of these references are incorporated herein by reference. See also U.S. Pat. No. 7,170,260 to Thrap (Maxwell Technologies), entitled, Rapid Charger for Ultracapacitors, which is incorporated herein by reference.

[0075] Referring now to FIG. **17**, there is shown another example of an electrical load **900'** of the present invention. Load **900'** has a supply input S and a ground output G, as with load **900**. A geomagnetic voltage source of the present invention is applied to terminals S and G. Load **900'** includes a charging and control circuit **902'**, a charge storage system **904'**, and an electric motor **906'**. Blocks **902'** and **904'** contain the same types of charging circuits and charge storage elements as in blocks **902** and **904** (FIG. **16**), respectively. Circuit **902'** further includes a control circuit or IC chip that controls the operation of switches SW**1** and SW**2** in FIG. **17**. In a first operating stage, switch SW**1** is closed and switch SW**2** is open, and the geomagnetic voltage source and circuit **902'** charge the storage element or elements of charge storage system **904'**. In a second operating stage, switch SW**1** is open (or sometimes remains closed) and switch SW**2** is closed, and system **904'** powers electric motor **906'**. Motor **906'** is typically a DC motor, but may be an AC motor if, e.g., an inverter is installed between the output of system **904'** and the motor. It is understood that, in an alternative embodiment, load **900'** may simply consist of motor **906'**, which would be directly driven by the geomagnetic voltage source.

[0076] Referring now to FIG. **18**, there is shown a further example of an electrical load **900"** of the present invention. Load **900"** has a supply input S and a ground output G, as with loads **900** and **900'**. A geomagnetic voltage source of the present invention is applied to terminals S and G. Load **900"** includes a charging and control circuit **902"**, a charge storage system **904"**, and an inverter or AC generator with step-up transformer **906"**. Blocks **902"** and **904"** contain the same types of circuits and charge storage elements as in blocks **902'** and **904'** (FIG. **17**), respectively. In a first operating stage of load **900"**, switch SW**1** is closed and switch SW**2** is open, and the geomagnetic voltage source and circuit **902"** charge the storage element or elements of charge storage system **904"**. In a second operating stage, switch SW**1** is open (or sometimes remains closed) and switch SW**2** is closed, and system **904"** powers inverter or AC generator with step-up transformer **906"**. If an inverter, block **906"** directly converts the DC voltage from block **904"** to AC voltage and steps up the voltage to a desired level. If an AC generator, block **906"** includes a DC motor for driving the AC generator and a step-up transformer raises the voltage to a desired level. In the latter case, block **904"** drives the DC motor, which in turn drives the AC generator. The desired level of AC voltage may be at the mains level so that it can be applied to the electric power grid, for contributing power to the grid. FIG. **18** shows the output of block **906"** being applied to an electric power grid.

[0077] The phrases, "earth's surface" and "the surface of the earth," when speaking about orientation or relative position (e.g., "a direction normal to the earth's surface"), mean the general or averaged plane of the surface if observed locally or the general tangent of the surface if observed from space. In addition, these phrases are to be construed broad enough to include the surface of any body of land, water or ice or any geological formation such as, e.g., a mountain top or slope, or a valley, whether above or below sea level.

[0078] In connection with the first through fifth and seventh embodiments of the present invention (FIGS. **7-11** and **13**), the insulated conductors (**112**, **116**, **212**, **216**, **312**, **316**, etc.) may be a 14-Gauge insulated Stranded THHN Cable, Model No. 22955957, supplied by Southwire Co., Carrollton, Ga.

[0079] While the preferred embodiments of the invention have been particularly described in the specification and illustrated in the drawing, it should be understood that the invention is not so limited. Many modifications, equivalents and adaptations of the invention will become apparent to those skilled in the art without departing from the spirit and scope of the invention, as defined in the appended claims.

What is claimed is:

1. A system for generating electricity from the geomagnetic field and the rotation of the earth, the earth rotating through the geomagnetic field to form a potential difference between first and second terrestrial charged bodies, the first and the second terrestrial charged bodies being spaced apart in a direction substantially normal to the earth's surface, said system comprising:

(a) an electrical load having a supply input and a ground output;

(b) a first current path, coupled to the first terrestrial charged body and to the supply input of said electrical load, for supplying the potential difference between the first and the second terrestrial charged bodies to said electrical load; and

(c) a second current path coupled to the ground output of said electrical load and to the second terrestrial charged body,

whereby an electric current related to the potential difference is generated in said electrical load.

2. The system of claim **1**, wherein the first terrestrial charged body includes a first portion of the earth located below the earth's surface and the second terrestrial charged body includes a second portion of the earth located at about or near the earth's surface, and wherein the earth contains an opening extending between the first and the second portions of the earth,

said first current path including (i) an electrically insulated conductor extending at least partially through the opening and (ii) a conductive contact member coupled to the electrically insulated conductor for establishing electrical contact between the first portion of the earth and the electrically insulated conductor.

3. The system of claim **2**, wherein said electrical load is located within the opening, between the first and the second portions of the earth.

4. The system of claim **2**, wherein the opening is a well bore or mine shaft, and wherein the first portion of the earth includes a bottom of a well or mine shaft, said electrically insulated conductor extending through the bore or mind shaft and the conductive contact member establishing electrical contact between the bottom of the well or mine shaft and the electrically insulated conductor.

5. The system of claim **4**, wherein the well bore or mine shaft is lined with a metal casing through which said electrically insulated conductor extends, the metal casing being in contact with the second portion of the earth and said second current path being in contact with the metal casing, such that said second current path is in electrical communication with the second portion of the earth.

6. The system of claim **5**, wherein said electrical load is located within the well bore or mine shaft and includes a rechargeable energy source and a pump, the electric current generated in the electrical load charging the rechargeable energy source and powering the pump.

7. The system of claim **1**, wherein the first terrestrial charged body is a portion of the earth at about or near the surface of the earth and the second terrestrial charged body is a cloud above the surface of the earth.

8. The system of claim **1**, wherein the first and the second terrestrial charged bodies are first and second portions of the earth, respectively, located at about or near the surface of the earth, the first portion of the earth being at a first elevation and the second portion of the earth being at a second elevation, the first elevation being different than the second elevation.

9. The system of claim **8**, wherein the first elevation of the first portion of the earth is at about or near the bottom of a mountain or cliff, and wherein the second elevation of the second portion of the earth is at a position on the mountain or cliff elevated from the bottom of the mountain or cliff.

10. The system of claim **1**, wherein the first terrestrial charged body is a portion of the earth at the bottom of a body of water, and wherein the second terrestrial charged body is water at about or near the surface of the body of water.

11. The system of claim **10**, wherein the body of water is a body of saltwater selected from the group consisting essentially of: ocean, sea, strait, saltwater canal, saltwater bay, saltwater lake, and saltwater river.

12. The system of claim **1**, wherein said first current path is substantially unshielded from the geomagnetic field.

13. The system of claim **1**, wherein said electrical load includes a rechargeable energy source including a rechargeable battery and a charging circuit coupled to the rechargeable battery.

14. The system of claim **13**, wherein said electrical load further includes an electric motor coupled to the rechargeable battery.

15. The system of claim **1**, wherein said electrical load includes a rechargeable energy source including one or more capacitors and a charging circuit coupled to the one or more capacitors.

16. The system of claim **15**, wherein the one or more capacitors are one or more ultracapacitors.

17. The system of claim **15**, wherein said electrical load further includes an electric motor coupled to the one or more capacitors.

18. A method of generating electricity from the geomagnetic field and the rotation of the earth, the earth rotating through the geomagnetic field to form a potential difference between first and second terrestrial charged bodies, the first and the second terrestrial charged bodies being spaced apart in a direction substantially normal to the earth's surface, said method comprising the steps of:

(a) providing a first current path having first and second electrically exposed ends;

(b) coupling the first end of the first current path to the first terrestrial charged body to establish electrical communication between the first current path and the first terrestrial charged body;

(c) coupling the second end of the first current path to a supply input of an electrical load to supply the potential difference to the electrical load;

(d) providing a second current path having first and second ends;

(e) coupling the first end of the second current path to a ground output of the electrical load; and

(f) coupling the second end of the second current path to the second terrestrial charged body to establish electrical communication between the electrical load and the second terrestrial charged body,

whereby an electric current related to the potential difference is generated in the electrical load.

19. The method of claim **18**, wherein step (a) includes providing a coaxial cable having a center conductor, insulation surrounding the center conductor, and an outer shield surrounding the insulation,

step (b) including coupling one end of the center conductor to the first terrestrial charged body, and

step (c) including coupling another end of the center conductor to the supply input of the electrical load, whereby the first current path includes the center conductor of the coaxial cable.

20. The method of claim **19**, further comprising the steps of:

(g) coupling a first end of the outer shield to the first terrestrial charged body; and

(h) coupling a second end of the outer shield to the second terrestrial charged body,

whereby a return current path is established between the first and the second terrestrial charged bodies.

21. The method of claim **20**, wherein step (f) includes coupling the second end of the second current path to the second end of the outer shield, to establish electrical communication between the electrical load and both the outer shield and the second terrestrial charged body.

22. The method of claim **20**, wherein the center conductor of the coaxial cable is substantially unshielded from the geomagnetic field.

23. A method of generating electricity from the geomagnetic field and the rotation of the earth, the earth rotating through the geomagnetic field to form a potential difference between first and second charged portions of the earth, the first and the second charged portions being spaced apart in a direction substantially normal to the earth's surface, said method comprising the steps of:

(a) providing a first conductor having first and second ends;

(b) coupling the first end of the first conductor to the first charged portion, to establish electrical communication between the first conductor and the first charged portion;

(c) coupling the second end of the first conductor to a supply input of an electrical load, to supply the potential difference to the electrical load;

(d) providing a second conductor having first and second ends;

(e) coupling the first end of the second conductor to a ground output of the electrical load; and

(f) coupling the second end of the second conductor to the second charged portion to establish electrical communication between the electrical load and the second charged portion,

whereby an electric current related to the potential difference is generated in the electrical load.

(57) **ABSTRACT**

A system for generating electricity from the geomagnetic field and rotation of the earth is presented. The earth rotates through the geomagnetic field to form a potential difference between first and second terrestrial charged bodies. The first and second charged bodies are spaced apart in a direction substantially normal to the earth's surface. The system comprises an electrical load, a first current path, and a second current path. The electrical load has a supply input and a ground output. The first current path is coupled to the first charged body and to the supply input of the electrical load, for supplying the potential difference to the electrical load. The second current path is coupled to the ground output of the electrical load and to the second charged body. As a result of this arrangement, an electric current related to the potential difference is generated in the electrical load.

FIG. 18

GENERATING ELECTRICITY FROM THE EARTH

BACKGROUND OF THE INVENTION

Field of Invention

The present invention relates generally to renewable electrical energy sources, and more particularly to apparatus and methods for generating electricity from the earth's magnetic field and rotation.

Background Art

The concepts of electromagnetic induction, Faraday's law, Faraday's disk, and the Lorentz force on charges are all well-known. These concepts have been applied to the earth, which is modeled as a large conductive sphere rotating through its own magnetic field ("geomagnetic field"). In this regard, the earth has been compared to a Faraday disk or homopolar generator. See, for example: W. M. Elsasser, The Earth as a Dynamo, Scientific American, Inc., Vol. 198, Issue 5, May 1, 1958, p. 44, 45; and C. R. Carrigan and D. Gubbins, The Source of the Earth's Magnetic Field, Scientific American, Inc., Vol. 240, Issue 2, Feb. 1, 1979, p. 118, 199-20. In making this comparison, the assumption has been carried over that the electricity to be obtained from the earth is from electromagnetic induction. Laboring under this assumption, it has been asserted that electricity from the geomagnetic field is not practicably retrievable, because the electricity gathering circuit would have to be stationary relative to the rotating earth (i.e., have a stationary frame of reference). This assertion is apparently based on a theory that the currents induced in the Faraday disk (or earth) and in the circuit employed to retrieve the electricity, would cancel each other out if both were moving through the magnetic field. Another theory is that a static electric field is created in the Faraday disk (or earth) that neutralizes the induced electric field, resulting in a zero voltage reading in the rotational frame of reference.

Further to this point, U.S. Patent App. Pub. No. 2004/0027022 (Feb. 12, 2004) to Weir, states that no voltage is generated by a Faraday type homopolar dynamo in the rotational reference frame of the dynamo (Weir, Par. [0010]). Weir even attempted to measure such voltage by mounting a voltmeter onto the rotating disk and connecting one probe to a shaft rotating the disk and the other probe to the rim of the disk. Weir states that the voltmeter read zero volts when the disk was rotating. (Weir Par. [0011].) No details are given regarding the sensitivity of the voltmeter or the test setup. In a book by Thomas Valone, Ph.D, P.E., entitled The Homopolar Handbook, published by Integrity Research Institute, Washington, D.C., 3rd Edition, October 2001 ("Valone I"), it is stated that an electrostatic field (created in response to the Lorentz force) neutralizes the electric field induced on the Faraday disk ("effective electric field"), and thus no voltage can be detected with a meter that rotates with the disk (Valone I, p. 7 & FIG. 8). Valone discusses his voltage measurement on page 24 and again at page 63. He indicates that his voltmeter was set to indicate a voltage reading only if the voltage was greater than 15 millivolts. Thus, the sensitivity of Valone's experiment may have been limited to 15 millivolts, presumably because the induced electric field (obtained in the stationary reference frame) was expected to be 100 millivolts (see Valone I, p. 63).

Valone reminds us that Michael Faraday, in 1831, compared his Faraday disk to the earth and the earth's rotation through its magnetic field. Valone states that Faraday, thinking that an induced voltage could be measured on his rotating disk, attempted to measure a like voltage in the earth (i.e., in rivers and streams) and apparently was unsuccessful. (Valone I, p. 61.) Valone characterizes Faraday's thinking as a mistake. Valone presumably mentions Faraday's unsuccessful attempt at measuring voltage in the earth as support for his position that a voltage cannot be measured in the rotating reference frame. In an earlier paper, entitled "The Homopolar Generator: Tesla's Contribution," Proceedings of the International Tesla Symposium, January 1986 ("Valone II"), Valone specifically stated that "we can't draw power from the earth's Homopolar generator while rotating with it." (Valone II, p. 273.)

Notwithstanding the view that a voltage is unobtainable in the rotating frame of reference in a Faraday system, proposals were made in the 1980s for a space shuttle to drag a tether (an insulated conductor) through space across the geomagnetic field to generate electric power onboard the shuttle. Current and a voltage potential difference would be induced on the tether's conductor as it passed through the magnetic field lines of the earth. The current return path (or ground path) would be the charged plasma medium of the ionosphere, which would exist between the outer wall of the space shuttle and the distal end of the tether (or an outer wall of a satellite attached to the distal end). A load (e.g., electronic equipment) inside the space shuttle would be connected between the proximal end of the tether and the outer wall of the shuttle (i.e., the return or ground path). A tether experiment was actually performed on a space shuttle mission in 1996, according to a NASA article (www.istp.gsfc.nasa.gov/Education/wtether.html). The voltage generated on the tether was 3500 volts, apparently measured in the rotational frame of reference. It is suggested that the voltage may have been measured at the distal end of the tether with instruments aboard a satellite connected to the distal end. The voltage level at the load inside the shuttle is not mentioned. In this experiment, the voltage applied to the intended load (equipment aboard the shuttle) was supplied by the tether's conductor and the return or ground path for the load was, according to NASA, the ionospheric plasma between the shuttle and the satellite.

An alternative design to the above-mentioned space tether was purportedly developed by or for the U.S. Army in 1988 and patented in U.S. Pat. No. 4,923,151 (1990) to Roberts. Roberts discloses a coaxial tether (Roberts, FIGS. 2 and 3) about 12.5 miles long, comprising an outer conductor 20, a magnetic shield conductor 26, and a center conductor 30. Outer conductor 20 is electrically connected at one end to a satellite 12 and at the other end to an orbiting shuttle 10 (Roberts, FIGS. 1 and 2). Center conductor 30 is magnetically shielded from the geomagnetic field by conductor 26, which is made of a high permeability metal such as soft iron. Center conductor 30 is electrically insulated from conductors 20 and 26 by insulation 28. Center conductor 30 is also electrically connected at one end to satellite 12 (at point 32) and at the other end to a load 36 inside shuttle 10 (through a switch 34). Load 36 is grounded via a return current path including the outer surface 40 of shuttle 10, conductor 20, and the outer surface 22 of satellite 12. The tether passes through the geomagnetic field at an orientation substantially normal to the earth and its magnetic field lines. As a result, a potential difference ("PD") is produced between shuttle 10 and satellite 12. Conductor 26 magnetically shields center conductor 30, so no induced current flows in conductor 30. Conductor 30 assumes the charge potential of satellite 12 and applies the potential difference PD across load 36 (once switch 34 is closed), causing current to flow in load 36. Conductor 20 replaces the ionosphere as the return current path, purportedly making the circuit more stable. Thus, conductor 20 functions both as a Faraday conductor (i.e., a conductor on which currents are induced from a magnetic field) and as the return current path. In this case, the Faraday conductor (conductor 20) does not function as the supply current path (conductor 30 does). In the previously discussed space tether design, the Faraday conductor (i.e., the tether's only conductor) did serve as the supply current path and did not serve as the return current path (the ionosphere).

For over 40 years, the inventor named herein has been working on an idea for generating electricity from the earth's rotation and magnetic field. The argument that electricity is generated in the earth is supported by some natural phenomena, including: the decreasing speed of the earth's rotation, the continued molten state of the earth's interior, volcanic and geyser activity, the earth's magnetic field, and lightning. The earth uses its primary kinetic energy, which originally started its rotation, to electrically charge itself by electromagnetic induction. Electric energy flowing toward the center of the earth is transformed into magnetic and heat energy, sustaining the earth's magnetic field and the molten state of the earth's interior. The balance in pressure between the surface and the molten interior is maintained through the loss of heat energy at the surface by heat radiation and volcanic and geyser activity. As a result of the work performed by the earth, and possibly because of a counter electromagnetic force (Lenz's law), the earth's kinetic energy is decreasing and its rotation is slowing.

The inventor herein began thinking about his idea while observing thunderstorms. In 1979, during one of his experiments, he was struck by a branch of lightning and luckily survived with no significant injury. He decided to continue experimentation, but in a safe manner. Upon arrival to the United States, the inventor herein applied for a grant and technical support from the National Institute of Standards and Technology (NIST) on May 18, 1995. His application was assigned an Evaluation Request (ER) Number 32042 and a Control Number 015351. The application was ultimately rejected with an explanation that the magnetic field rotates with the earth and thus currents could not be induced in a conductor installed on the earth. NIST's rejection of the idea dissuaded the inventor herein from pursuing the idea further, until recently when the inventor started thinking about the Faraday disk and "Faraday's paradox."

Faraday's paradox is the non-intuitive result that electric currents are induced in the Faraday disk even when the magnet rotates with the disk. It is non-intuitive because many would assume that the magnetic field rotates with the rotating magnet and disk, in which case currents would not be induced in the disk. Faraday conducted three tests to investigate this phenomenon. First, he rotated the disk and kept the magnet stationary and observed a current induced in the disk. Second, he kept the disk stationary and rotated the magnet and observed no induced current in the disk. Third, he rotated the disk and magnet together and observed a current in the disk. From these tests, Faraday concluded that the magnetic field remained stationary when the magnet was rotated around its own magnetic axis. Similarly, the earth (representing a rotating disk and magnet) should produced a stationary magnetic field through which the earth rotates, thus inducing generally radial electric currents in the earth and on conductors substantially aligned with the earth's radius. Since Faraday, there has been a long-standing debate and experimentation about Faraday's paradox and whether or not the magnetic field rotates with the magnet. For example, see Valone I, pp. 2-4 and 37. Notwithstanding the theoretical debate and investigation, it is believed that Faraday was correct and that currents are induced by the geomagnetic field in the earth, in the surrounding atmosphere, and in conductors appropriately located on the earth and in the atmosphere.

Nikola Tesla disclosed a conductor extending into the atmosphere and normal to the earth's surface in U.S. Pat. No. 685,957 (Tesla). Rather than seek to induce currents in the conductor from the geomagnetic field, Tesla sought to collect radiant energy (or particles charged by radiant energy) primarily from the sun. Tesla somehow suspended a conductive plate P and connected it to the distal end of the conductor (Tesla, FIG. 1). The proximal end of the conductor was connected to a capacitor C. The other end of capacitor C was connected to a secondary conductor, which is, in turn, connected to a conductive plate P' grounded in the earth. Plate P was the collector of radiant energy charged particles. The charge from plate P charged capacitor C. A voltage threshold device (d) and a load R are connected across capacitor C to form a circuit. Device (d) closes the circuit when the charge on capacitor C exceeds a predetermined voltage, causing the voltage to be applied to load R. In this patent, Tesla does not seek to obtain the potential difference between two "terrestrial charged bodies" (hereinafter defined).

Herein, the term "terrestrial" is used in a broad sense, to include the whole or any part of the earth and its surrounding atmosphere, including but not limited to: the earth's inner and outer cores, mantle, crust, any layer or level thereof, and its surface; all bodies of water; air; clouds; ice; vegetation; minerals and other resources such as oil; rocks including basalt; or any other composition or thing of the earth and its atmosphere. As used herein, the term "terrestrial charged body" (or its plural form) means a terrestrial body, region, layer, zone, other volume or area, any composition or thing, with or without specifically defined or fixed boundaries, having an electric charge represented by a voltage potential.

OBJECTS AND SUMMARY OF THE INVENTION

It is therefore an object of the present invention to overcome the problems and limitations associated with the prior art and to fulfill a long-felt but unsolved need for a renewable source of energy.

It is another object of the present invention to provide a clean and renewable source of electrical energy.

It is a further object of the present invention to generate electricity from the earth's magnetic field and rotation.

It is yet another object of the present invention to provide a reliable source of electricity from the earth's magnetic field and rotation.

It is yet a further object of the present invention to provide a source of electricity from the earth's magnetic field and rotation that can be easily implemented.

It is still another object of the present invention to provide a source of electricity from the earth's magnetic field and rotation that can be implemented at a low-cost.

These and other objects are attained in accordance with the present invention, wherein there is provided a system for generating electricity from the geomagnetic field and rotation of the earth. The earth rotates through the geomagnetic field to form a potential difference between first and second terrestrial charged bodies. The first and second terrestrial charged bodies are spaced apart in a direction substantially normal to the earth's surface. The system comprises an electrical load, an electrically insulated first current path, and a second current path. The electrical load has a supply input and a ground output. The first current path is coupled to the first terrestrial charged body and to the supply input of the electrical load, for supplying the potential difference to the electrical load. The second current path is coupled to the ground output of the electrical load and to the second terrestrial charged body. As a result of this arrangement, an electric current related to the potential difference is generated in the electrical load.

In one particular embodiment, the first terrestrial charged body includes a first portion of the earth located below the earth's surface and the second terrestrial charged body includes a second portion of the earth located at or near the earth's surface. The earth contains an opening extending between the first and the second portions of the earth. In this embodiment, the first current path includes (i) an electrically insulated conductor extending at least partially through the opening and (ii) a conductive contact member coupled to the electrically insulated conductor for establishing electrical contact between the first portion of the earth and the electrically insulated conductor. In a more specific embodiment, the opening is a well bore or mine shaft, and the first portion of the earth includes a bottom of a well or mine. The electrically insulated conductor extends through the bore or mine shaft, and the conductive contact member establishes electrical contact between the bottom of the well or mine and the electrically insulated conductor.

In another embodiment, the first terrestrial charged body may be a portion of the earth at or near the surface of the earth, and the second terrestrial charged body may be a cloud above the surface of the earth. In yet another embodiment, the first and second terrestrial charged bodies may be first and second charged portions of the earth, respectively, where both portions are located at or near the surface of the earth. In this latter embodiment, the first portion of the earth is at a first elevation and the second portion of the earth is at a second and different elevation. For example, the first elevation may be at or near the bottom of a mountain or cliff and the second elevation may be at an elevated position on the mountain or cliff. In still another embodiment, first terrestrial charged body is a portion of the earth at the bottom of a body of water, such as the ocean, and the second terrestrial charged body is the water at or near the surface of the body of water.

In any of the embodiments, the electrical load may include a rechargeable energy source, including a rechargeable battery or battery pack and a charging circuit coupled to the rechargeable battery or pack. Alternatively, or in addition to batteries, the rechargeable energy source may include a charging capacitor or a bank of charging capacitors along with an appropriate charging circuit for the capacitor(s). The capacitor or capacitors may be ultracapacitors. The electrical load may further include an electric motor coupled to the rechargeable energy source. The electric motor may be a DC motor, which may be mechanically coupled to an AC generator. In operation, the DC motor would actuate the AC generator, resulting in the AC generator generating AC electric power. Alternatively, the electric load may include an inverter for converting DC electric power to AC electric power. In either case (AC generator or inverter), the AC electric power can be stepped up in voltage and applied to an electric power grid.

A method of generating electricity from the geomagnetic field and rotation of the earth is also within the scope of the present invention. As indicated earlier, the earth rotates through the geomagnetic field to form a potential difference between first and second terrestrial charged bodies. The first and second terrestrial charged bodies are spaced apart in a direction substantially normal to the earth's surface. The method comprises the steps of: (a) providing an electrically insulated first current path having first and second electrically exposed ends; (b) coupling the first end of the first current path to the first terrestrial charged body to establish electrical communication between the first current path and the first terrestrial charged body; (c) coupling the second end of the first current path to a supply input of an electrical load to supply the potential difference to the electrical load; (d) providing a second current path having first and second ends; (e) coupling the first end of the second current path to a ground output of the electrical load; and (f) coupling the second end of the second current path to the second terrestrial charged body to establish electrical communication between the electrical load and the second terrestrial charged body. As a result of these steps, an electric current related to the potential difference is generated in the electrical load.

BRIEF DESCRIPTION OF THE DRAWING

Further objects of the present invention will become apparent from the following description of the preferred embodiments, with reference to the accompanying drawing, in which:

FIG. **1** is a diagram of a test setup used to demonstrate the operation of a Faraday disk and the generation of electricity within the rotational frame of reference;

FIGS. **2** is a diagram of an experiment showing a rotating Faraday disk with a voltmeter having lead wires and test leads for measuring voltages at different points along the disk's radius;

FIG. **3** is a diagram of an experiment illustrating a battery analogy of the Faraday disk and the concept of short circuit (SC) current on the disk;

FIG. **4** is a diagram of a field experiment with one embodiment of the present invention, implemented in conjunction with a water well;

FIG. **5** is a diagram of the earth rotating through its magnetic field and showing (schematically) three terrestrial charged bodies spaced apart from each other in a direction normal to the earth's surface;

FIG. **6** is a diagram of the earth partially dissected to reveal a portion of a flat circular plane through the earth's equator, presented as an analogy of a Faraday disk;

FIG. **7** is a diagram of a first embodiment of the present invention, wherein the terrestrial charged bodies are separated portions of the earth;

FIG. **8** is a diagram of a second embodiment of the invention, which is an implementation utilizing a well;

FIG. **9** is a diagram of a third embodiment of the invention, which is an implementation utilizing a mine and a mine shaft;

FIG. **10** is a diagram of a fourth embodiment of the invention, which is an implementation utilizing a body of water, wherein one terrestrial charged body is the bottom of the body of water and another terrestrial charged body is a surface of the body of water;

FIG. **11** is a diagram of a fifth embodiment of the invention, which is an implementation utilizing different elevations of the earth's surface, such as associated with a mountain or cliff;

FIG. **12** is a diagram of a sixth embodiment of the invention, which is an implementation utilizing the atmosphere of the earth, wherein one terrestrial charged body is a cloud and another terrestrial charged body is a surface of the earth;

FIG. **13** is a diagram of a seventh embodiment of the invention, which is an implementation utilizing a well having a bore casing and an electrical load (which may include a submersible pump) is located at least partially within the bore casing;

FIG. **14** is a diagram of an eighth embodiment of the invention, which employs coaxial conductors to carryout the invention;

FIG. **15** is a cross-sectional view of the coaxial conductors of FIG. **14**, taken along line **15-15** in FIG. **14**;

FIG. **16** is a block diagram of one example of an electrical load of the present invention, which is a rechargeable energy source including a charging circuit and a charge storage device, such as a rechargeable battery(s) or storage capacitor (s);

FIG. **17** is a block diagram of another example of an electrical load of the invention, which includes a charging and control circuit, charge storage device, and an electric motor; and

FIG. **18** is a block diagram of a further example of an electrical load of the present invention, including a charging and control circuit, a charge storage device, and an inverter or AC generator with step-up transformer.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

Inspired by the book "The Homopolar Handbook" by Thomas Valone (Valone I), the named inventor built a Faraday disk to perform a few original experiments. A direct consequence of the experiments is the extraction and use of one part of the existing electrical energy of the earth. FIG. **1** illustrates a Faraday disk apparatus **10** built by the inventor herein. Apparatus **10** includes a frame **12** made of 2×6 wooden boards, connected together with screws. An axle **14** is made of a ⅝ inch diameter, 3-foot long steel threaded rod. Axle **14** has a sharpened lower end **14***a*, which rests on a steel plate **16**. Axle **14** is rotatably supported by two bearing assemblies **18***a* and **18***b*. Bearing assembly **18***a* is mounted in an upper cross member **12***a* of frame **12** and bearing assembly **18***b* is mounted in a bottom cross member **12***b* of frame **12**. A drill **20** is connected, via a chuck **22**, to a short rod **24**, which is, in turn, connected to one end of an insulator block **26**. The upper end of axle **14** is connected to the other end of insulator block **26**. Rod **24**, block **26** and axle **14** rotate together as a unit. The speed of drill **20** is manually controlled to control the rotational speed of axle **14**. Insulator **26** electrically isolates axle **14** from the drill to eliminate any chance of electric current from drill **20** finding its way into axle **14**.

As further shown in FIG. **1**, the actual Faraday disk comprises a 17-inch diameter round aluminum baking pan **28** and two 16-inch diameter (and ¼-inch thick) steel disks **30***a* and **30***b*. Pan **28** and disks **30***a*, **30***b* are fixed together and balanced on axle **14**, using washers and steel hex nuts threaded on axle **14**. Disk **30***a* is fixed in and against the bottom of pan **28** and disk **30***b* is fixed directly underneath and against pan **28** (collectively referred to as disk assembly **28'**). Axle **14** and disk assembly **28'** rotate together, almost like a spinning top. In order to reduce electrical resistance associate with axle **14** above disk assembly **28'**, a copper ring **32** is clamped to axle **14** and an insulated copper wire **34** is connected between ring **32** and disk assembly **28'**. Two spring-loaded graphite brush contacts **34***a* and **34***b* are installed. Brush contact **34***a* is adjacent to and in contact with copper ring **32** and brush contact **34***b* is adjacent to and in contact with the rim of disk assembly **28'**. Contact **34***a* and a lead wire **36***a* electrically connect ring **32** to one input of a digital voltmeter **38**. Contact **34***b* and a lead wire **36***b* electrically connect the rim of disk assembly **28'** to a second input of voltmeter **38**. Voltmeter **38** is mounted outside of frame **12** and is held stationary. Another digital voltmeter **40** is mounted on disk assembly **28'** and rotates with assembly **28'**. Voltmeter **40** is electrically connected, via a short lead wire **42***a*, to the rim of disk assembly **28'** and is electrically connected, via a longer lead wire **42***b*, to axle **14**. A digital camera **44** is fixed on axle **14** (just below insulator block **26**) to record the digitally displayed readings of voltmeter **40**.

Again referring to FIG. **1**, twenty-two cylindrical welding magnets, each five inches in diameter and each with a pull strength of 75 lbs, are arranged to form two magnetic cylinders **46***a* and **46***b* (11 magnets each). Cylinders **46***a* and **46***b* are separated from each other by disk assembly **28'**. Magnetic cylinders **46***a*, **46***b* are installed in a way that allows them to be held stationary or to be rotated with disk assembly **28'**. In a series of tests, axle **14** was rotated at a speed of about 200 RPM and voltmeter **38** measured and read a generated potential difference of about 300 millivolts. No difference in voltage generation was noted between tests where magnetic cylinders **46***a*, **46***b* were held stationary or rotated (Faraday's paradox). During the 200 RPM tests, voltmeter 40 read 1 to 3 millivolts, supporting the view that a voltage potential difference is generated and measurable on the rotating frame of reference. These tests are referred to collectively as "Experiment A." The difference in readings between voltmeter **38** and voltmeter **40** will be explained below.

Referring now to FIG. **2**, a diagram of a rotating disk experiment is shown. Disk assembly **28'** and voltmeter **38** are used in this experiment. Lead wires **36***a* and **36***b* of voltmeter **38** include test leads **48***a* and **48***b*, respectively. Leads **48***a*, **48***b* are placed on rotating disk assembly **28'** in a sliding engagement to establish dynamic electrical contact with assembly **28'**. As disk assembly **28'** was rotated, voltage measurements were taken at different points along the radius of the assembly (i.e., at different imaginary concentric circles on disk assembly **28'**). Voltmeter **38** measured the potential difference between the points of contact. The positive side of the potential difference is toward the center, as indicated in FIG. **2**, due to the Lorentz force pushing electrons radially out to the rim. The measured potential difference increased as the distance between the contact points increased. This experiment is referred to hereinafter as "Experiment B."

An understanding as to why there is a difference in electric potential measured by voltmeter **38** and voltmeter **40** (FIG. **1**) was gained in another experiment, illustrated in FIG. **3**. In this experiment, an attempt was made to model the electrodynamics on a rotating Faraday disk. This was done by applying a potential difference across disk assembly **28'** (between axle **14** and the rim), while disk assembly **28'** remained stationary (as did voltmeter **38**). This setup was intended to mimic the case where the voltmeter and disk are rotating in the same frame of reference. The potential difference was applied across disk assembly **28'** using a 6-volt battery **50**. This modeled the potential difference generated on a rotating disk by electromagnetic induction. Insulated copper wires **52***a* and **52***b* were connected to the terminals of battery **50** and to axle **14** and the rim of disk assembly **28'**, as shown in FIG. **3**. The positive side of battery **50** is connected at axle **14** and the negative side is connected at the rim to model the charge displacement due to induction. Lead wires **36***a*, **36***b* of voltmeter **38** were also connected to disk assembly **28'**, in the vicinity of the connections of wires **52***a*, **52***b*, respectively. The voltage (or potential difference) measured by voltmeter **38** was 50 millivolts. A reading of 6 volts would be expected in an open circuit measurement. On the other hand, a reading of 50 millivolts would suggest a near short circuit (considering the inherent resistance in disk assembly **28'**). Voltmeter **38** did measure a short circuit current, which is indicated in FIG. **3** by arrow SC. This experiment is referred to hereinafter as "Experiment C."

Based on Experiments A, B and C, it was concluded that the rotation of disk assembly **28'** in the magnetic field (created by magnetic cylinders **46***a*, **46***b*—FIG. **1**) caused the disk assembly to become charged and develop a potential difference in the radial direction. The potential difference increased as the distance between the center of disk assembly **28'** and a measurement point along the radius of assembly **28'** increased. This potential difference was created by the Lorentz force pushing electrons out to the rim, causing an induced current to flow radially outward. In response to the induced potential difference, electrons seek to establish equilibrium on the disk (as it is a conductor) and begin to flow in a direction opposite of the induced current. This opposite flow of electrons is referred to as the short circuit current and is indicated in FIG. **3** by arrow SC. It is believed that this short circuit current is flowing at all times on a rotating Faraday disk. This may be the reason why a voltage is measureable on the rotating frame of reference (voltmeter on the disk), albeit a smaller voltage than the induced voltage measured in the stationary frame of reference. A rotating Faraday disk (i.e., disk assembly **28'**) behaves like a battery (or multiple batteries connected in series) with one pole at the center of the disk (axle **14**) and the other pole at the rim. While rotation in the magnetic field causes the disk to be charged, a short circuit simultaneously occurs. The disk loses its charge immediately when it stops rotating. A Faraday disk (and thus disk assembly **28'**) can be thought of as comprising a number of imaginary annular rings, each behaving like a circular-shaped battery and the batteries are connected in series. Thus, the largest potential would occur at the rim, where all of the annular rings (batteries) of the disk are in series and in the circuit.

The concepts studied in the lab in Experiments A, B and C were then applied in the field, with respect to the earth's rotation and magnetic field. FIG. **4** illustrates an experiment that was conducted at two different drilled water wells, one 117 feet deep and the other 210 feet deep. The wells were drilled at construction sites of new homes in a suburban area near Utica, N.Y. At the time of the experiments, the wells were not in use. There were no electric power lines or transmitting antennas within a great distance around the construction sites. A copper pipe **54**, one-half inch in diameter and two feet long, was connected to an insulated copper wire **56**, to ensure a good connection with the earth at the bottom of the well. Pipe **54** and wire **56** were lowered to the bottom of each well. Pipe **54** made direct contact with the earth at the bottom of each well. The bottom of each well is considered a first charged body (defined above). Another one-half inch diameter and two-foot long copper pipe **58** was hammered into the ground at the surface, about 6 feet from the well. The surface and earth surrounding pipe **58** is considered a second charged body. A digital voltmeter **60** was used to measure the difference in electric potential between the bottom of the well and the surface of the ground (i.e., between the first and the second charged bodies). Voltmeter **60** has test lead wires **62** and **64**. Test lead wire **62** is connected to insulated wire **56** and test lead wire **64** is connected to copper pipe **58**. Steady measurements of **592** millivolts were obtained in the 117-foot well and 858 millivolts were obtained in the 210-foot well. Short circuit current between the surface and the bottom of the well was also measured with meter **60**. As the distance between the surface and bottom of the well increased, the difference in electric potential increased.

A variation of the setup in FIG. **4** was also tested at the 210-foot well (indicated in dash lines). The well includes a metal bore casing **66** that extends substantially down the well bore. The variation is that casing **66** was used as part of the circuit instead of copper pipe **58**. Test lead wire **64** was connected directly to casing **66**. The voltage measurements were consistent with those obtained in the original tests for the 210-foot well. It is believed that the use of casing **66** as part of the circuit, instead of a ground pipe (like pipe **58**), may yield more consistent voltage readings. The tests performed at both wells, as described in this and the previous paragraph, are collectively referred to hereinafter as "Experiment D." In the tests of Experiment D, wire **56** was an insulated 14-Gauge Stranded THHN Cable, Model No. 22955957, supplied by the Southwire Company, Carrollton, Ga., featuring conductors made of annealed (soft) copper, rated at 600 Volts, and insulated with tough, heat- and moisture-resistant PVC. Voltmeter **60** was a Mini Pocket MultiMeter, Model DM110, by Extech Instruments Corp., Nashua, N.H., with 0.1 millivolt DC voltage resolution and 0.01 milliamp DC current resolution. Another voltmeter was also used to re-confirm the readings. That meter was a Cen-Tech Seven Function Digital Multimeter, Model 98025, supplied by Harbor Freight Tools Co., Camarillo, Calif., with milliamp and millivolts resolutions.

The earth is an oblate spheroid with an equatorial radius of 6378.16 km. The earth and its surrounding atmosphere rotate within the earth's magnetic field (i.e., the geomagnetic field). The speed of a point at the earth's equator is about 463.8 m/sec. In the Utica, N.Y. area, where Experiment D was performed, the speed is about 300 m/sec. By comparison, the speed of sound is 340.29 m/sec. The earth's magnetic field is estimated to be about 0.35 to 0.65 gauss at the earth's surface. By comparison, a strong refrigerator magnet has a field strength of 100 gauss. The geomagnetic field is generally dipolar as it has two poles, the north and south magnetic poles, and the field lines resemble those of a dipolar magnet. FIG. **5** illustrates the geomagnetic field on one side of the earth's magnetic axis **70**. Generally, the earth can be considered a conductor having the following five parts: (1) the solid inner core, which is an excellent conductor; (2) the molten outer core, which is an excellent conductor; (3) the mantle, much of which is a good conductor; (4) the crust, which is a relatively good conductor; and (5) the atmosphere, which can be a good or poor conductor.

To help with the understanding of the results obtained in Experiment D and with the operation of the present invention, consider the following theory. (This theory should not be construed as defining or limiting the scope of the present invention in any way, and it should not affect the validity of the invention if proven to be incorrect. It is presented in the hope that it may aid in the understanding of the invention.) One should picture the earth and the surrounding (rotating) atmosphere as an endless number of concentric spheres, from the earth's center to the earth's surface, and from the earth's surface to the outer reaches of the surrounding, rotating atmosphere. FIG. **5** depicts two spheres associated directly with the earth itself. A sphere **72** represents any level or layer under the earth's surface between the center and the surface. For example, sphere **72** could be (generally) a junction between the earth's crust and its mantle, a junction between the earth's mantle and the outer core, or a particular layer within the earth's crust or mantle. A sphere **74** represents the earth's surface. Alternatively, one can picture the earth as an endless number of disks, with the largest diameter disk cutting through the equator (see FIG. **6**) and the smallest diameter disks approaching the poles.

As shown in FIG. **5**, the geomagnetic field (showing one side of the field) comprises a plurality of magnetic field lines **68** disposed generally in a dipolar arrangement about magnetic axis **70**. As the earth rotates through the geomagnetic field, it behaves similar to a rotating Faraday disk, in that electrons dislocate outward from the center to the surface. This causes a potential gradient to be established along the radius of the earth and into the atmosphere, with the positive side toward the center and the negative side toward the surface. A potential difference is measured between any two designated spheres of the earth and atmosphere (e.g., spheres **72** and **74** in FIG. **5**), and the potential difference increases with the spacing between the designated spheres. At the same time, electrons travel back toward the center of the earth as the electromagnetic system seeks equilibrium, and this causes a permanent short circuit current to flow in the earth's interior.

Continuing with the theory, induction also exists in the atmosphere, especially in the clouds. Clouds are connected to the earth's surface by air that is generally a poor conductor. Some short circuit current through dry air may exist, but a big difference in electric potential develops between clouds and the earth's surface. During storms, the air between the earth's surface and clouds, and between clouds at different levels (representing different spheres), become saturated with water and form columns that are relatively good conductors. An intense short circuit current occurs through such conductors. When the amount of current becomes so intense that the conductor cannot accept it any longer, because of its properties (air and water), it simply burns out. The flash and explosion (i.e., lightning and thunder) are results of the burning out of the overloaded conductor. Most likely, a similar event happened to NASA's tether experiment, when an almost 20 km long insulated wire burned out by an estimated 1 amp of current at 3500 volts (see NASA tether experiment article, www.istp.gsfc.nasa.gov/Education/wtether.html).

Further with the theory, the earth behaves like one huge battery (similar to Faraday's disk), constantly being charged by the rotation within its own magnetic field. One pole of the battery is at the earth's center and the other pole is at the earth's surface or at some designated point in the atmosphere. One can also imagine the earth as an endless number of sphere-shaped batteries connected in series. At the same time, a permanent short circuit in the earth exists, like the battery in Experiment C above.

It is not possible or practicable to obtain the electric potential between the center of the earth and its surface using Faraday's approach, because stationary brush contacts cannot be placed at the center and the surface (i.e., a stationary frame of reference for the collection circuit cannot be established). However, it is possible to obtain an electric potential from the short circuit current between different designated spheres reachable from the earth's surface (e.g., Experiment D).

Referring again to FIG. **5**, sphere **72** contains a designated terrestrial charged body **76** and sphere **74** (earth's surface) contains a designated terrestrial charged body **78**. A cloud **80** in the atmosphere **82** is also designated as a terrestrial charged body. Terrestrial charged bodies **76**, **78** and **80** are spaced apart from each other in a direction substantially normal to the earth's surface. An imaginary axis **84** represents the alignment of the charged bodies in a direction normal to the surface. Due to electromagnetic induction, a potential difference is formed between terrestrial charged bodies **76** and **78**, between charged bodies **76** and **80**, and between charged bodies **78** and **80**. A terrestrial charged body is that amount (e.g., area or volume) of earth, water, minerals, rocks, clouds, etc. sufficient to define, accumulate or hold a charge which can produce a measurable potential difference with another terrestrial charged body.

Referring to FIG. **6**, there is shown a model of the earth with a portion removed to reveal an imaginary plane or disk **86**. Disk **86** cuts through the equator. FIG. **6** illustrates an analogy between the earth's interior and a Faraday disk (see earlier discussion above). In this example, an interior section or region of the earth's crust or mantle serves as a first terrestrial charged body **88**, and the earth's surface serves as a second terrestrial charged body **90**. Compare FIG. **6** with FIG. **2**. The rotation of the earth through its magnetic field causes terrestrial bodies **88** and **90** to become charged and a potential difference to be form between them, as in Experiment B (FIG. **2**).

Referring now to FIG. **7**, a system **100** for generating electricity from the geomagnetic field and rotation of the earth is shown as a first embodiment of the present invention. As explained, a potential difference (PD) is formed between terrestrial charged bodies—here terrestrial charged bodies **102** and **104**. In this embodiment, body **102** is underground earth (e.g., rock, soil, and/or minerals, etc.) at the bottom of an opening or hole (man-made or natural) and body **104** is the surface soil of the earth. Charged bodies **102**, **104** are spaced apart in a direction normal to the earth's surface. System **100** comprises an electrical load **106** having an input **108** and an output **110**. A first insulated conductor **112** is coupled at one end to charged body **102** via a contact member **114** and is connected at its other end to load input **108**. Contact member **114** may be, e.g., a short (e.g., 2 ft long) piece of copper or aluminum pipe. Conductor **112** is insulated to avoid direct electrical contact with the earth, except for charged body **102**. Conductor **112** is soldered or otherwise electrically connected to contact member **114**. The other end of conductor **112** is either directly connected to load input **108** (as shown) or is coupled to input **108** via a jumper wire and/or a connector. In FIG. **7**, a first current path is defined between load **106** and body **102** by contact member **114** and conductor **112**. The first current path supplies the PD to load **106**. A second insulated conductor **116** is coupled at one end to charged body **104** via a contact member **118** and is connected at the other end to load output **110**. Contact member **118** may be the same type as contact member **114**. Conductor **116** may be the same type and model as conductor **112**. A second current path is defined between load **106** and body **104** by conductor **116** and contact member **118**. A return current path occurs between charged bodies **104**, **102** via the intervening earth. Thus, a complete electrical circuit is established from charged body **102**, contact member **114**, conductor **112**, load **106**, conductor **116**, contact member **118**, charged body **104**, and the return current path back to charged body **102**. An electric current related to the PD is generated in load **106**. Load **106** may comprise a charging circuit and a charge storage device, a motor, and/or an AC generator or inverter, as discussed later. Contact members **114**, **118** may be any form of electrical conductor, including but not limited to a plate, disk, sphere, cone, rod, cylinder (hollow or solid), or sharp pointed member or members.

Referring now to FIG. **8**, a system **200** for generating electricity from the geomagnetic field and rotation of the earth is shown as a second embodiment of the present invention. A potential difference PD is formed between spaced apart terrestrial charged bodies **202** and **204**. Body **202** is underground earth at the bottom of a well and body **204** is the surface soil of the earth. The well includes a drilled wellbore extending from the earth's surface to the well bottom. A metal casing **203** extends down into the bore. At the bottom of the well is a supply of water **205**. System **200** comprises an electrical load **206** having an input **208** and an output **210**. A first insulated conductor **212** is coupled at one end to charged body **202** via a contact member **214** and is connected at its other end to load input **208**. Contact member **214** may be submerged in water **205**. Conductor **212** is insulated to avoid direct electrical contact with metal casing **203** and the earth, except for charged body **202**. A first current path is defined between load **206** and body **202** by conductor **212** and contact member **214**. This current path supplies the PD to load **206**. A second insulated conductor **216** is coupled at one end to charged body **204** via a connection (e.g., a solder joint) **217** to casing **203**. Conductor **216** is connected at its other end to load output **210**. A second current path is defined between load **206** and body **204** by conductor **216**, connection **217** and casing **203**. A return current path occurs between charged bodies **204**, **202** via casing **203** and the earth (and/or water **205**). Thus, a complete electrical circuit is established from charged body **202**, contact member **214**, conductor **212**, load **206**, conductor **216**, connection **217**, casing **203**, charged body **204**, and the return current path back to charged body **202**. An electric current related to the PD is generated in load **206**. In this embodiment, it is preferred that the bottom of the well be at least **400** feet deep relative to the surface.

Referring now to FIG. **9**, a system **300** for generating electricity from the geomagnetic field and rotation of the earth is shown as a third embodiment of the present invention. A potential difference PD is formed between spaced apart terrestrial charged bodies **302** and **304**. In this embodiment, body **302** is underground earth at a bottom of a mine and body **304** is the surface soil of the earth. The mine contains a drilled or excavated opening or mineshaft extending from the earth's surface to the bottom. A metal frame **303** may be present in the shaft. System **300** comprises an electrical load **306** having an input **308** and an output **310**. A first insulated conductor **312** is coupled at one end to charged body **302** via a contact member **314** and is connected at its other end to load input **308**. Contact member **314** makes direct contact with the bottom of the mine and, in some cases, may slightly penetrate the bottom. Conductor **312** is insulated to avoid direct electrical contact with frame **303** and/or the earth (except for charged body **302**). A first current path is defined between load **306** and body **302** by conductor **312** and contact member **314**. The first current path supplies the PD to load **306**. A second insulated conductor **316** is coupled at one end to charged body **304** via a contact member **318** and is connected at its other end to load output **310**. Contact member **320** has been driven into the earth to make good electrical contact with body **304**. Alternatively, conductor **316** may be coupled to body **304** via a connection (e.g., a solder joint) **320** to metal frame **303** (if any). A second current path is defined between load **306** and body **304** by conductor **316** and contact member **318** (or by conductor **316**, connection **320** and frame **303**). A return current path occurs between charged bodies **304**, **302** via the earth or, alternatively, via frame **303** and the earth. Thus, a complete circuit is established from charged body **302**, contact member **314**, conductor **312**, load **306**, conductor **316**, contact member **318** (or connection **320** and frame **303**), charged body **304**, and the return current path back to charged body **302**. An electric current related to the PD is generated in load **306**.

Referring now to FIG. **10**, a system **400** for generating electricity from the geomagnetic field and rotation of the earth is shown as a fourth embodiment of the present invention. A potential difference PD is formed between spaced apart terrestrial charged bodies **402** and **404**. In this embodiment, charged body **402** is the bottom or bed of a body of water (e.g., the earth's crust, basalt, sand, clay, sediments or other settled materials, a change in salinity, etc.). Charge body **404** is the water at or near the surface of the body of water. The body of water is preferably a salt water system such as an ocean, sea, ocean bay, strait, estuary, lake, and the like. System **400** comprises an electrical load **406** having an input **408** and an output **410**. A first insulated conductor **412** is coupled at one end to charged body **402** via a contact member **414** and is connected at its other end to load input **408**. Contact member **414** makes direct contact with the bottom and, in some cases, may penetrate the bottom. Conductor **412** is insulated to avoid direct electrical contact with the body of water. A first current path is defined between load **406** and body **402** by conductor **412** and contact member **414**. The first current path supplies the PD to load **406**. A second insulated conductor **416** is coupled at one end to charged body **404** via a metal boat **418**, which serves as a contact member. Conductor **416** is connected at its other end to load output **410**. Conductor **416** is directly connected to boat **418**, as represented by the electrical ground symbol. An alternative contact member may be a thin metal (e.g., copper or aluminum) plate **418'**, which floats on the water. In the latter case, conductor **416** is directly connected to plate **418'**. A second current path is defined between load **406** and body **404** by conductor **416** and boat **418** (or by conductor **416** and plate **418'**). A return current path occurs between charged bodies **404**, **402** via the body of water. Thus, a complete circuit is established from charged body **402**, contact member **414**, conductor **412**, load **406**, conductor **416**, boat **418** or other contact member, charged body **404**, and the return current path back to charged body **402**. An electric current related to the PD is generated in load **406**.

Referring now to FIG. **11**, a system **500** for generating electricity from the geomagnetic field and rotation of the earth is shown as a fifth embodiment of the present invention. A potential difference PD is formed between spaced apart terrestrial charged bodies **502** and **504**. In this embodiment, both charged bodies **502**, **504** are portions of the earth at or near the earth's surface, but body **504** is at a higher elevation than body **502**. This may be the case, for example, at a mountain or cliff System **500** comprises an electrical load **506** having an input **508** and an output **510**. A first insulated conductor **512** is coupled at one end to charged body **502** via a contact member **514** and is connected at its other end to load input **508**. Contact member **514** is driven into the earth to establish good electrical contact with charged body **502**. Conductor **512** is insulated to avoid direct electrical contact with the earth. A first current path is defined between load **506** and body **502** by conductor **512** and contact member **514**. The first current path supplies the PD to load **506**. A second insulated conductor **516** is coupled at one end to charged body **504** via a contact member **518** and is connected at its other end to load output **510**. Member **518** has been driven into the earth to make good electrical contact with body **504**. A second current path is defined between load **506** and body **504** by conductor **516** and contact member **518**. A return current path occurs between charged bodies **502**, **504** via the intervening earth. Thus, a complete circuit is established from charged body **502**, contact member **514**, conductor **512**, load **506**, conductor **516**, contact member **518**, charged body **504**, and the return current path back to charged body **502**. An electric current related to the PD is generated in load **506**.

Referring now to FIG. **12**, a system **600** for generating electricity from the geomagnetic field and rotation of the earth is shown as a sixth embodiment of the present invention. A potential difference PD is formed between spaced apart terrestrial charged bodies **602** and **604**. In this embodiment, charged body **604** is a cloud or a stream of clouds passing overhead and charged body **602** is a portion of the earth at or near the earth's surface. A preferred location for system **600** is at a high elevation, such as a mountain top, where low lying clouds are a frequent occurrence. As air is generally a poor conductor, the flow of short circuit current between clouds and the earth's surface is very limited, resulting in the buildup of a huge difference in electrical potential between the clouds and the earth's surface. THIS EMBODIMENT IS VERY DANGEROUS DUE TO LIGHTNING STRIKES AND STATIC ELECTRICITY. ANYONE WHO BUILDS THIS EMBODIMENT, WHETHER AUTHORIZED BY THE INVENTOR HEREIN OR NOT, ASSUMES ALL RISK OF PERSONAL INJURY OR DEATH AND ASSUMES ALL LIABILITY TO OTHERS INJURED OR KILLED AS A RESULT OF THE CONSTRUCTION AND/OR OPERATION OF THIS EMBODIMENT.

Again referring to FIG. **12**, system **600** comprises an electrical load **606** having an input **608** and an output **610**. A first insulated conductor **612** is coupled at one end to charged body **602** via a contact member **614** and is connected at its other end to load input **608**. Contact member **614** has been driven into the earth to make good electrical contact with body **602**. A first current path is defined between load **606** and body **602** by conductor **612** and contact member **614**. The first current path supplies the PD to load **606**. A second insulated conductor **616** is coupled at one end to charged body **604** via a contact apparatus **618** and is connected at its other end to load output **610**. Apparatus **618** includes a non-conductive tower **618***a*, an upwardly extending metal bracket **618***b*, and a metal collector plate **618***c*. Tower **618***a* is preferably built from a non-conductive material such as, for example, wood, fiberglass, fiberglass reinforced plastic, and the like. Tower **618***a* may be supported by non-conductive guy wires such as Phyllistran guys or Polygon structural fiberglass guys. Alternatively, tower **618***a* may be electrically insulated from the ground using an electrically insulating barrier between the tower and the ground. Conductor **616** is electrically connected to metal bracket **618***b*. Conductor **616** is insulated to avoid electrical contact with the surrounding atmosphere. Bracket **618***b* and collector plate **618***c* establish electrical coupling with the electric charge in cloud **604**. Plate **618***c* is a metal sheet of metal, such as copper or aluminum. A second current path is defined between load **606** and body **604** by conductor **616**, metal bracket **618***b*, and collector plate **618***c*. A return current path occurs between charged bodies **604**, **602**, via the atmosphere or moisture or precipitation in the atmosphere. Thus, a complete circuit is established from charged body **602**, contact member **614**, conductor **612**, load **606**, conductor **616**, bracket **618***b*, collector plate **618***c*, charged cloud **604**, and the return current path back to charged body **602**. An electric current related to the PD is generated in load **606**.

As mentioned, the hazards of lightning are obviously a major concern in system **600**. Lightning protection schemes are not infallible and no representation is made herein that system **600** is safe from the hazards of lightning strikes or static electricity. In system **600**, a surge arrester device **620** is installed between load output **610** and ground (FIG. **12**). Device **620** is shown as a gas-filled surge arrester, but the preferred arrester is a spark gap rated for lightning strike voltages. Preferably, conductor **616** is a high voltage stranded single conductor cable, such as used to connect lightning rods to grounding rods, but covered with insulation having a high dielectric strength to withstand lightning strikes.

An alternative embodiment to system **600** (not shown) is to replace apparatus **618** with a hydrogen- or helium-filled balloon (e.g., a weather balloon). The balloon would have a conductor such as copper or aluminum foil wrapped around it or a metal plate or band mounted on it. In this embodiment, insulated conductor **616** would be electrically connected to the conductor on the balloon. This embodiment would otherwise be the same as system **600**. The warnings and disclaimers made above with respect to system **600** are equally applicable to this embodiment.

Referring now to FIG. **13**, a system **700** for generating electricity from the geomagnetic field and rotation of the earth is shown as a seventh embodiment of the present invention. This embodiment concerns a well and is fundamentally the same as the second embodiment, except here the electrical load is located down in the wellbore. A potential difference PD is formed between terrestrial charged bodies **702** and **704** (i.e., bottom of well and earth surface). The well includes a drilled bore and a metal casing **703** extending down into the bore. At the bottom of the well is a supply of water **705**. An electrical load **706** has an input **708** and an output **710**. A first insulated conductor **712** is coupled at one end to charged body **702** via a contact member **714** and is connected at its other end to load input **708**. A first current path is defined between load **706** and body **702** by conductor **712** and contact member **714**. The first current path supplies the PD to load **706**. A second insulated conductor **716** is coupled at one end to charged body **704** via an electrical connection (e.g., a solder joint) **717** to metal casing **703**. The other end of conductor **716** is connected to load output **710**. A second current path is defined between load **706** and body **704** by conductor **716**, connection **717** and casing **703**. A return current path occurs between charged bodies **704**, **702**, via casing **703** and the earth (and/or water **705**). Thus, a complete electrical circuit is established from charged body **702**, contact member **714**, conductor **712**, load **706**, conductor **716**, connection **717**, casing **703**, charged body **704**, and the return current path back to charged body **702**. An electric current related to the PD is generated in load **706**. In the case where casing **703** is not made of electrically conductive material, an alternative coupling arrangement with charged body **704** is: conductor **716** is connected to a contact member **718**, which is driven into the ground at the earth's surface.

Load **706** may contain a charge storage system and a wellbore submersible pump controlled by a control unit **720**. The charge storage system stores electricity generated by system **700** and supplies the stored electricity to the pump when called upon by control unit **720**. Control unit **720** communicates with the pump via a control cable **722**. Control unit **720** includes an auto-control function that controls the pump automatically. Unit **720** switches on the power to the pump by means of a pressure switch actuated in response to a pressure valve or by means of a float level switch actuated by a float. An example of a submersible pump powered by a renewable electrical energy source is disclosed in U.S. Pat. No. 7,837,450, which is incorporated herein by reference.

Referring now to FIGS. **14** and **15**, a system **800** is another embodiment of the present invention. This embodiment is characterized by a coaxial cable **801** installed between two spaced apart, substantially parallel, terrestrial charged bodies **802** and **804**. Cable **801** includes a copper (or copper-clad steel) center conductor **812** insulated by a dielectric insulating material **812***a*, such as cellular polyurethane, polyurethane foam or solid polyethylene. Cable **801** further includes an outer shield conductor **803**, which may be a woven braid of bare or tinned copper wires, a wrap of aluminum foil tape, a solid copper or aluminum tube, or a combination thereof. Shield conductor **803** may be insulated or left uninsulated. In FIGS. **14** and **15**, conductor **803** is insulated generally by a jacket **803***a* made of plastic, such as polyvinyl chloride (PVC). When cable **801** is installed, jacket **803***a* is preferably removed between charged bodies **802** and **804**, as shown in FIG. **14**. System **800** comprises an electrical load **806** having a supply input and a ground output made available at a threaded female coaxial connector **808**. Cable **801** has a finished proximal end with a threaded male coaxial connector **809**. Connector **809** is considered male because it has a stinger wire, which is to be inserted into connector **808**. The stinger wire is connected to or an extension of center conductor **812**. Connector **809** includes a threaded slip ring **809***a* for threading connector **809** onto connector **808**.

Once connectors **808** and **809** are connected together, center conductor **812** is in electrical contact with the supply input of load **806** and shield conductor **803** is in electrical contact with the ground output of load **806**. Center conductor **812** is electrically coupled to charged body **802** via a metal contact member **814**. Conductor **812** delivers the potential difference between charged bodies **802**, **804** to load **806**. Shield conductor **803** is electrically coupled to charged body **804** by direct contact as shown. Thus, the ground output of load **806** is electrically coupled to charged body **804**. Conductor **803** is also coupled to charged body **802** by direct contact as shown. Alternatively, conductor **803** may be in direct contact with a portion of the earth defined to be outside of charged body **802** (thus making indirect contact with body **802**). A return current path occurs between charged bodies **802**, **804** primarily through shield conductor **803**. Using conductor **803** as the return current path improves return path performance by making the path easier to implement and maintain, and it operates more predictably because it is not dependent on the variable properties and conditions of earth, water, atmospheric, and other natural or in situ return current paths. In system **800**, a complete electrical circuit is established from charged body **802**, contact member **814**, center conductor **812**, load **806** (via connectors **809/808**), shield conductor **803** (via connectors **808/809**), charged body **804**, and shield conductor **803** back to charged body **802**. An electric current related to the PD between charged bodies **802**, **804** is generated in load **806**.

As shown in FIG. **14**, an alternative or additional ground output **810** is provided in electrical load **806**. An insulated conductor **816** is connected to output **810** and to a contact member **818**. In this case, shield conductor **803** may be decoupled from the original ground output, for example, by operation of an automatic impedance sensing switch internal to load **806**. Optionally, both outputs (**810** and original output via **803**) may be in operation together. In connection with output **810**, the return current path remains primarily through shield conductor **803**. The complete electrical circuit is from charged body **802**, contact member **814**, center conductor **812**, load **806** (via connectors **809/808**), conductor **816**, contact member **818**, charged body **804**, and shield conductor **803** back to charged body **802**.

Referring now to FIG. **16**, there is shown one example of an electrical load **900** of the present invention. A supply input S and a ground output G of load **900** correspond to, for example, load input **108** and load output **110**, respectively (e.g., see FIG. **7**). The potential difference between a pair of terrestrial charged bodies, obtained in accordance with the present invention, is presented across terminals S and G of load **900**. The apparatus of the present invention that obtains this potential difference (examples of which are shown in FIGS. **7-14**) is referred to in FIGS. **16-18** as a geomagnetic voltage source. Load **900** includes a charging circuit **902** and a charge storage system **904**. The specifics of charging circuit **902** depend upon the type of charge storage system used. System **904** may be, for example, a rechargeable battery or series of batteries or a charging capacitor or bank of charging capacitors. A basic charging circuit for a rechargeable battery (or series of batteries) may be a positive going diode in series with a source resistor, and both in series with the rechargeable battery (or series of batteries). A basic charging circuit for a capacitor (or bank of capacitors in series) may be an inductor in series with the capacitor (or bank of capacitors). The latter circuit typically includes a switching element or elements to cause the geomagnetic voltage source to charge the inductor in a first switched state and to cause the charged inductor to charge the capacitor or capacitors in a second switched state. If capacitors are used for the charge storage elements, a preferred form of capacitor is the ultracapacitor. Ultracapacitors and their charging circuits are disclosed in the following references: M. S. W. Chan, K. T. Chau, and C. C. Chan, Effective Charging Method for Ultracapacitors, Journal of Asian Electric Vehicles, Vol. 3, No. 2, December 2006, pp. 771-76; and Maxwell Technologies Application Note, Document 1008981 Rev 1, December 2005, pp. 2-3. The disclosures of these references are incorporated herein by reference. See also U.S. Pat. No. 7,170,260 to Thrap (Maxwell Technologies), entitled, Rapid Charger for Ultracapacitors, which is incorporated herein by reference.

Referring now to FIG. **17**, there is shown another example of an electrical load **900'** of the present invention. Load **900'** has a supply input S and a ground output G, as with load **900**. A geomagnetic voltage source of the present invention is applied to terminals S and G. Load **900'** includes a charging and control circuit **902'**, a charge storage system **904'**, and an electric motor **906'**. Blocks **902'** and **904'** contain the same types of charging circuits and charge storage elements as in blocks **902** and **904** (FIG. **16**), respectively. Circuit **902'** further includes a control circuit or IC chip that controls the operation of switches SW1 and SW2 in FIG. **17**. In a first operating stage, switch SW1 is closed and switch SW2 is open, and the geomagnetic voltage source and circuit **902'** charge the storage element or elements of charge storage system **904'**. In a second operating stage, switch SW1 is open (or sometimes remains closed) and switch SW2 is closed, and system **904'** powers electric motor **906'**. Motor **906'** is typically a DC motor, but may be an AC motor if, e.g., an inverter is installed between the output of system **904'** and the motor. It is understood that, in an alternative embodiment, load **900'** may simply consist of motor **906'**, which would be directly driven by the geomagnetic voltage source.

Referring now to FIG. **18**, there is shown a further example of an electrical load **900"** of the present invention. Load **900"** has a supply input S and a ground output G, as with loads **900** and **900'**. A geomagnetic voltage source of the present invention is applied to terminals S and G. Load **900"** includes a charging and control circuit **902"**, a charge storage system **904"**, and an inverter or AC generator with step-up transformer **906"**. Blocks **902"** and **904"** contain the same types of circuits and charge storage elements as in blocks **902'** and **904'** (FIG. **17**), respectively. In a first operating stage of load **900"**, switch SW**1** is closed and switch SW**2** is open, and the geomagnetic voltage source and circuit **902"** charge the storage element or elements of charge storage system **904"**. In a second operating stage, switch SW**1** is open (or sometimes remains closed) and switch SW**2** is closed, and system **904"** powers inverter or AC generator with step-up transformer **906"**. If an inverter, block **906"** directly converts the DC voltage from block **904"** to AC voltage and steps up the voltage to a desired level. If an AC generator, block **906"** includes a DC motor for driving the AC generator and a step-up transformer raises the voltage to a desired level. In the latter case, block **904"** drives the DC motor, which in turn drives the AC generator. The desired level of AC voltage may be at the mains level so that it can be applied to the electric power grid, for contributing power to the grid. FIG. **18** shows the output of block **906"** being applied to an electric power grid.

The phrases, "earth's surface" and "the surface of the earth," when speaking about orientation or relative position (e.g., "a direction normal to the earth's surface"), mean the general or averaged plane of the surface if observed locally or the general tangent of the surface if observed from space. In addition, these phrases are to be construed broad enough to include the surface of any body of land, water or ice or any geological formation such as, e.g., a mountain top or slope, or a valley, whether above or below sea level.

In connection with the first through fifth and seventh embodiments of the present invention (FIGS. **7-11** and **13**), the insulated conductors (**112**, **116**, **212**, **216**, **312**, **316**, etc.) may be a 14-Gauge insulated Stranded THHN Cable, Model No. 22955957, supplied by Southwire Co., Carrollton, Ga.

While the preferred embodiments of the invention have been particularly described in the specification and illustrated in the drawing, it should be understood that the invention is not so limited. Many modifications, equivalents and adaptations of the invention will become apparent to those skilled in the art without departing from the spirit and scope of the invention, as defined in the appended claims.

What is claimed is:

1. A method of generating electricity from the geomagnetic field and rotation of the earth, the earth rotating through the geomagnetic field to form a potential difference between first and second earth-bound terrestrial charged bodies, the first and the second earth-bound terrestrial charged bodies being spaced apart in a direction substantially normal to the earth's surface, said method comprising the steps of:

(a) using a system including (i) an electrical load having a supply input and a return output, (ii) a first current path having a first end coupled to the supply input of the electrical load, and (iii) a second current path having a first end coupled to the return output of the electrical load;

(b) coupling a second end of the first current path to the first earth-bound terrestrial charged body and coupling a second end of the second current path to the second earth-bound terrestrial charged body, such that the electrical load is electrically coupled to the first and the second earth-bound terrestrial charged bodies; and

(c) generating in the electrical load an electrical current related to the potential difference formed between the first and the second earth-bound terrestrial charged bodies by the earth's rotation through the geomagnetic field.

2. The method of claim **1**, wherein the first earth-bound terrestrial charged body includes a first portion of the earth located below the earth's surface and the second earth-bound terrestrial charged body includes a second portion of the earth located at about or near the earth's surface, and wherein the earth contains an opening extending between the first and the second portions of the earth,

said first current path including (i) an electrically insulated conductor extending at least partially through the opening and (ii) a conductive contact member coupled to the electrically insulated conductor for establishing electrical contact between the first portion of the earth and the electrically insulated conductor.

3. The method of claim **2**, wherein the electrical load is located within the opening, between the first and the second portions of the earth.

4. The method of claim **2**, wherein the opening is a bore or shaft of a well or mine, the well or mine including a bottom, and wherein the first portion of the earth includes the bottom of the well or mine, said electrically insulated conductor extending through the bore or shaft and the conductive contact member establishing electrical contact between the bottom of the well or mine and the electrically insulated conductor.

5. The method of claim **4**, wherein the bore or shaft is lined with a metal casing, the metal casing being in contact with the second portion of the earth and the second current path being in contact with the metal casing, such that the second current path is in electrical communication with the second portion of the earth.

6. The method of claim **1**, wherein the first and the second earth-bound terrestrial charged bodies are first and second portions of the earth, respectively, located at about or near the surface of the earth, the first portion of the earth being at a first elevation and the second portion of the earth being at a second elevation, the first elevation being different than the second elevation.

7. The method of claim **1**, wherein the first earth-bound terrestrial charged body is a portion of the earth at a bottom of a body of water, and wherein the second earth-bound terrestrial charged body is water at about or near the surface of the body of water.

8. The method of claim **7**, wherein the body of water is a body of saltwater.

9. The method of claim **1**, wherein the electrical load includes a rechargeable energy source, said method further comprising the step of

(c) charging the rechargeable energy source with the electric current generated in step (c).

10. The method of claim **9**, wherein the electrical load further includes an electric pump, said method further comprising the step of

(d) powering the electric pump with the rechargeable energy source.

11. The method of claim **9**, wherein the electrical load includes an electric motor, said method further comprising the step of

(d) powering the electric motor with the rechargeable energy source.

12. The method of claim **1**, wherein the electrical load includes an electric pump, said method further comprising the step of

(c) powering the electric pump with the electric current generated in step (c).

13. The method of claim **1**, wherein the electrical load includes an electric motor, said method further comprising the step of

(c) powering the electric motor with the electric current generated in step (c).

14. The method of claim **1**, wherein the electrical load includes a rechargeable energy source including a rechargeable battery and a charging circuit coupled to the rechargeable battery.

15. The method of claim **14**, wherein the electrical load further includes an electric motor coupled to the rechargeable battery.

16. The method of claim **1**, wherein the electrical load includes a rechargeable energy source including a one or more capacitors and a charging circuit coupled to the one or more capacitors.

17. The method of claim **16**, wherein the one or more capacitors are one or more ultracapacitors.

INTRODUCTION

The purpose of this report is to provide the circuit analysis, working drawings, component specifications and component manufactures for Mr. Edwin Gray's patent number 4,595,975 **-** Efficient Power Supply Suitable for Inductive Loads.

This information is for **SCIENTIFIC RESEARCH** only in order to more fully understand the scientific principles demonstrated by Gray's pat no. 4,595,975.

In the spirit of open information and cooperation between scientist, researchers and business professionals, this information is open to the public and may be reproduced and distributed by anyone for the purpose of providing scientific research information

WARNING! Gray's Circuit pat. no. 4,595,975 contains a very HIGH POWER CAPACITOR

that is DANGEROUS! Experimentation with this circuit requires at least the

formal education of a licensed electrician. If you perform research with this circuit,

YOU DO SO AT YOUR OWN RISK. Follow all standard safety precautions and use a proper laboratory to conduct testing.

If you follow the instructions, the circuit will work. I have confirmed this with actual test runs. It is my sincere hope that clean, efficient means to generate electricity will evolve from this information for the benefit of everyone. Mr Gary Magratten

Circuit Section 1. Battery to transformer:

The batteries should be deep cycle golf cart batteries, 12 volts and under 200 A hrs Use true deep cycle batteries. Automotive batteries are designed for high current for a short period of time. Deep cycle batteries provide steady current and can handle repeated recharging. A deep cycle battery rated at 200 A hrs should deliver 10 amps of current for 20 hrs.

There are three ways to accomplish this section of the circuit. Working drawing no.1 show all three ways. First, and easiest for research is the use of 110 AC house current at 15 amps to the primary of a transformer and a 3,000 volt, .5 amp AC secondary. The second is a 12 volt battery, DC, to a chopper-vibrator which produces 12 volt AC for the transformer. The design of the chopper-vibrator will be described separately later. This requires a special transformer with a 12 volt AC at 100 amps to the primary. The primary side also requires a center tap. The secondary is 3,000 volts and .5 amps AC. The third, is to use a deep cycle battery 12 volts, 100 amps and an inverter to form 110 AC at 11 amps. The transformer should then be rated at 110 volts at II amps on the primary and
3,000 volts and .4 amps.
Include a switch and a fuse into the circuit as shown on the working drawings.

Working Drawing no. 2

Circuit #2 - Transformer to Full Wave Bridge:

From the secondary of the transformer there is 3,000 volts and .5 amps alternating current. The full wave bridge converts the alternating current to direct current pulses. Position the diodes of the bridge for a positive terminal close to the transformer and the negative terminal away from the battery. To build a full wave bridge you can use four diodes or a one piece full wave bridge unit. The rating of the diodes is 8,000 PIV (peak inverse voltage) and .5 amp forward current.

Circuit Subsection 3A: - Full Wave Bridge to the

Capacitor #1:

In subsection 3A the full wave bridge can be treated as a direct current source with a positive terminal and a negative terminal. The voltage available is 3,000 volts at .5 amps. The positive terminal of the full wave bridge is connected to the positive side of Capacitor #1.

The negative terminal of the full wave bridge is connected to the negative side of Capacitor #1. The positive terminal of the capacitor is directly connected to the high-voltage anode of the CSET.

The negative terminal of the battery is connected to the negative terminal of the full wave bridge. Then the negative terminal of the full wave bridge is connected to the negative side of Capacitor #1.

THIS IS VERY IMPORTANT. THE 3,OOOvolts

.5 amp DIRECT CURRENT IS COUPLED WITH THE l2volt, 100 amps AVAILABLE FROM THE

BATTERY. THIS GIVES A 300 Kva CHARGE TO CAPACITOR #1. THIS IS VERY HIGH POWER

and DANGEROUS!

I found this difficult to understand but the technical discussion from Mr. Richard Hackenburger (Mr. Gray’s electrical engineer clearly shows ZS6Kva of instantaneous power available from Capacitor #1.) Careful examination of the wiring diagram will confirm this statement. Pulses of direct current are built up (technically called RAMPING) on capacitor #1 to be available for the arc in the CSET.

Circuit Subsection 3C. From the collector grids of the CSET to the Load to the plate of Capacitor #2.

THIS SECTION 15 UNUSUAL AND THEREFORE DIFFICULT TO

COMPREHEND, PLEASE HAVE PATIENCE!

The wave form of this section of the circuit is very unusual. This may be what was termed “Cold Electricity”. I have to do laboratory test to verify this explanation. Circuit Subsection 3C extends from the collector plates in the CSET to the Load to the Capacitor #2.

The LOAD and the CSET will be treated a separate subjects. The collector plates are exposed to the high-voltage anode 3,000 volt positive potential when the circuit switch on the low voltage side of the CSET is open. The 3,000 volt positive potential draws electrons to the collector plates from the circuit.

When the switch is quickly closed then reopened [.00005 sec] an ARC forms in the spark gap between the low voltage anode’s available current and the high voltage anode 3,000 volt positive potential. When an ARC is formed it is commonly accepted knowledge that the atmosphere is ionized to form positive ions and negative ions[free electrons].

When the ARC occurs, The Electrons Give Up Quanta or Photons of Electromagnetic Radiation. This is evidenced by the flame like discharge of visible light. This release of EMR or Radiant Event induces a current in the collector plates. This is the Photoelectric Effect to which the discovery is accredited to A, Einstien,

The ARC charges the copper tubes(collector grids 34A and 34 B) at the end near the spark gap.

The charge moves down the tube to the wire that is located at the end of the this slowly, and step by step.

Once again the switch is open and the 3,000 volt positive potential returns to the high voltage anode, and the process begins again.

Think of the circuit that extends from the collector plates through the LOAD to the Capacitor #2 plate as a column of fluid in a pipe, that is first stressed or subjected to suction, then compressed by pressure, in a repetitive manner. in the same manner the circuit is stressed then compressed with short duration, high-voltage, high-current energy spikes.

A single energy spike is capable of repelling like charged electromagnets with great force. This is how the motor was powered.

As the instantaneous energy spike travels through the load an EMF is produced about the inductor, be they electromagnets or a transformer.

When the energy spike ceases, the EMF is absorbed back into the inductor and on to the Capacitor #2 which is a coupling capacitor in that it draws current from the positive terminal of the battery thus recharging the battery.

BATTERY

Circuit Subsection 3D: From Capacitor #2 to the Battery.

This section of the circuit extends from the plate of Capacitor #2 to the positive terminal of the battery. According to the patent the CEME is transferred through Capacitor #2 to recharge the battery.

I am going to propose a slight change in the design. This is the only place where I deviate from the patent and the schematic as originally presented. [I would also like to state that during my efforts to reconstruct this circuit, I wasted a many hours trying to second guess the information and take short cuts. The message here is to follow the patent and the schematic, the device does work.)

The change in the design is the introduction of a diode from one plate of the capacitor to the other with the forward current flow in the direction of the LOAD. **I have NOT TESTED THIS YET**. Here is the reason for the proposed change in the design. Capacitor #2 is a coupling capacitor in that it conducts alternating-current but blocks the transmission of steady direct current. For the sake of analysis let us say that pulsed direct current can be treated the same as alternating current with respect to the capacitor#2 in that the changing value of voltage and current are coupled through the dielectric.

When the low-voltage switch of the commutator is open, no power is flowing in the circuit. The high-voltage anode is at a charged state of 3,000 volts. This draws electrons to the collector plates from the plate of the capacitor #2.

The deficit of electrons on Plate C of the capacitor#2 becomes a positive potential. The plate B of capacitor #2 becomes negatively charged by drawing electrons from the positive terminal of the battery**. This is the same way a battery charger works.**

By introducing a high current diode from plate B to Plate C of Capacitor#2, a one-way-path is created for the current drawn from the positive terminal of the battery.

When the commutator switch is closed and power is flowing in the circuit an **ARC** is created from the low voltage anode to the high voltage anode. This **ARC** [EMR or Radiant Energy] is absorbed by the collector grids 34a and 34b.

This pulse of power induces a spike of energy [**high-voltage, high-current, short duration pulse** I through the wire back to plate C of capacitor #2, which had a positive potential.

The power pulse arrives on the plate C and distributes electrons on the plate. These electrons can travel no further than the plate because the diode prevents the transfer of electrons to plate B.

The commutator switch is opened and the high-voltage potential returns to the high-voltage anode of the CSET.

The cycle repeats itself and electrons are drawn to the collector plates by the high positive potential of the high- voltage anode. The introduction of a **HIGH CURRENT DIODE** from plate B to plate C creates a one-way-path for current to be drawn from the positive terminal of the battery to allow the battery to be recharged.

Circuit Section 4: Battery Charging Circuit.

THIS SECTION IS NOT EXPLAINED BY THE PATENT. SIMPLY TRACING THE CURRENT FLOW WIll VERIFY THIS ANALYSIS.

The battery charging circuit extends from the positive terminal of the battery through the commutator; through the triode; to the low voltage anode; across the spark gap; to the high voltage anode; to DIODE 46; to the negative terminal of the battery.

IT IS CRITICAL TO THE UNDERSTANDING OF HOW THIS CIRCUIT WORKS TO COMPREHEND THE DIRECTION OF CURRENT FLOW IN THIS SECTION OF THE CIRCUIT! THE CURRENT FLOW IS FROM THE POSITIVE TERMINAL OF THE BATTERY THROUGH THIS CIRCUIT TO THE NEGATIVE TERMINAL OF THE BATTERY! THIS IS OPPOSITE THE NORMAL DIRECTION OF A DIRECT ***CURRENT CIRCUIT. THINK OF IT THE SAME AS A BATTERY CHARGER.***

Current is drawn from the positive terminal of the battery through the TRIODE through the CSET to the high -voltage anode and then to the plate of capacitor#l.

The 3,000 volt positive potential overcomes the 12 volt positive potential at the terminal of the battery. Most of the current is delivered to the plate of capacitor#l.

The 12 volt negative potential provided by the negative terminal of the battery draws a small portion of the current through DIODE 46 back to the battery to provide a pulsed recharging current. The current directed back to the battery through **DIODE 46** is probably only .04 amps.

A MUCH LARGER PULSE IS CREATED ON THE BACK PLATE OF CAPACITOR #1 THAT IS WIRED BACK TO THE NEGATIVE TERMINAL OF THE BATTERY TO PRODUCE A RECHARGING CURRENT.

When **ARC OVER** occurs at the spark gap in the CSET, a pulse of current is directed to the high-voltage positive potential developed on the plate of capacitor #1 facing the CSET.

Capacitor #1 is a coupling capacitor in that it transfers the power pulse. This pulse of current repels electrons from the other plate of capacitor#1 forming a current pulse back to the battery of about 10 amps [depending on the current available from the low voltage anode at the time of ARC OVER.]

This Is the Primary Means By Which the Battery is Recharged While Driving the

Transformer

CHOPPER - VIBRATOR CIRCUIT

Load Circuit.

Circuit Section 5. Chopper-Virator Circuit.

If you use a 12 volt battery for the primary energy source to drive the transformer, then the 12 volts direct current must be changed to 12 volts alternating current as an alternating current is necessary to power an inductor.

A simple chopper- vibrator constructed from a common alarm bell available at any hardware store can be used.

An Alarm bell consist of two small electromagnets and a spring held lever. The contacts make and break the circuit to switch the circuit at a very low frequency. Please look at the working drawing, Circuit Section 5WD. As stated before, you can power the transformer with 110 house current or a 12 volt battery to an inverter and then on to the transformer.

If you use 12 volts DC and the chopper-vibrator to form 12 volts AC , you must use a transformer that has a center tap on the primary side. Johnson Electric Coil Co. is familiar with the design. Ask to talk with Ms. Beth Bockes, design engineer.

AUTOMOTIVE TYPE POINTS

DURATION .0005 SEC.
FREQUENCY 120 PULSES / SEC.
MOTOR RPM 3600

This circuit creates the short duration [.0005 sec.] current pulse necessary for the formation of the ARC in the CSET. There are many ways to accomplish this.

You can use a TRIODE or a FAST-RECOVERY DIODE.

If you use a fast-recovery diode, you can place mechanical switching in the circuit line from the positive terminal of the battery to the diode.

If you use a triode, you must control the grid of the triode with a separate circuit.

MAKE SURE THE TRIODE OR THE DIODE IS INSTALLED IN THE DIRECTION OF THE CURRENT FLOW WHICH IS FROM THE POSITIVE TERMINAL OF THE BATTERY TO THE CSET. With a TRIODE, the cathode goes to the pos. terniinal of the battery and the plate goes to the CSET. With a high current fast recovery DIODE, the cathode goes to the pos. terminal of the battery and the anode goes to the CSET.

If the intended purpose of the LOAD is a Gray type motor, then one **PULSE** of power is required to repel like pole electromagnets arranged slightly offset from each other.

If the intended purpose of the LOAD is to run a direct current system, the LOAD could be a deep cycle battery from which current is drawn to power a circuit.

If the LOAD is standard type AC, 60 hertz, lights and electrical equipment then a step-down transformer that provides narrow pulsed direct current of a duration around .0005 sec. at a frequency of 120 pulses per sec. is suggested.

THE KEY HERE IS TO DESIGN THE WAVE FORM TO MEET THE NEEDS OF THE EQUIPMENT YOU

ARE TRYING TO POWER.

I have only run a mechanical switch made of a simple electric motor, a cam and a set of points connected to a diode. I performed two successful test runs.

MANY PEOPLE HAVE ASKED,” WHY DON’T YOU TRY THIS?”. Here is why.

FROM THE MAGNITUDE OF THE POWER DISCHARGE IN THE CSET, I REALIZED THAT SAFETY REQUIRES ANY FUTHER TEST RUNS BE DONE IN IN A LABORATORY WITH QUALIFIED HELP.

I am negotiating with a laboratory now, but because of the cost it may be months before the laboratory, test equipment and qualified personnel are organized and funded.

This is HIGH -VOLTAGE, HIGH-CURRENT PULSES OF ELECTRICAL POWER CONVERTED TO **ELECTROMAGNETIC RADIATION** of unknown frequency and therefore DANGEROUS. All known methods of generating electrical energy are dangerous but we know what we are working with. This is research, PROCEED CAREFULLY and SAFELY.

Here are three ways to a accomplish the switching. The first is a mechanical switch consisting of an octagonal cam (nut) mounted on a motor shaft and a set of automotive points.

If you place the mechanical switching in the circuit line then an automotive type capacitor across the points may be helpful to prevent arcing. If you use mechanical switching to control the grid of a triode, then the capacitor is probably not necessary.

Circuit Subsection 6A. A mechanical switch consisting of a motor, a octagonal cam a set of automotive points. See working drawing. To achieve the .0005 sec

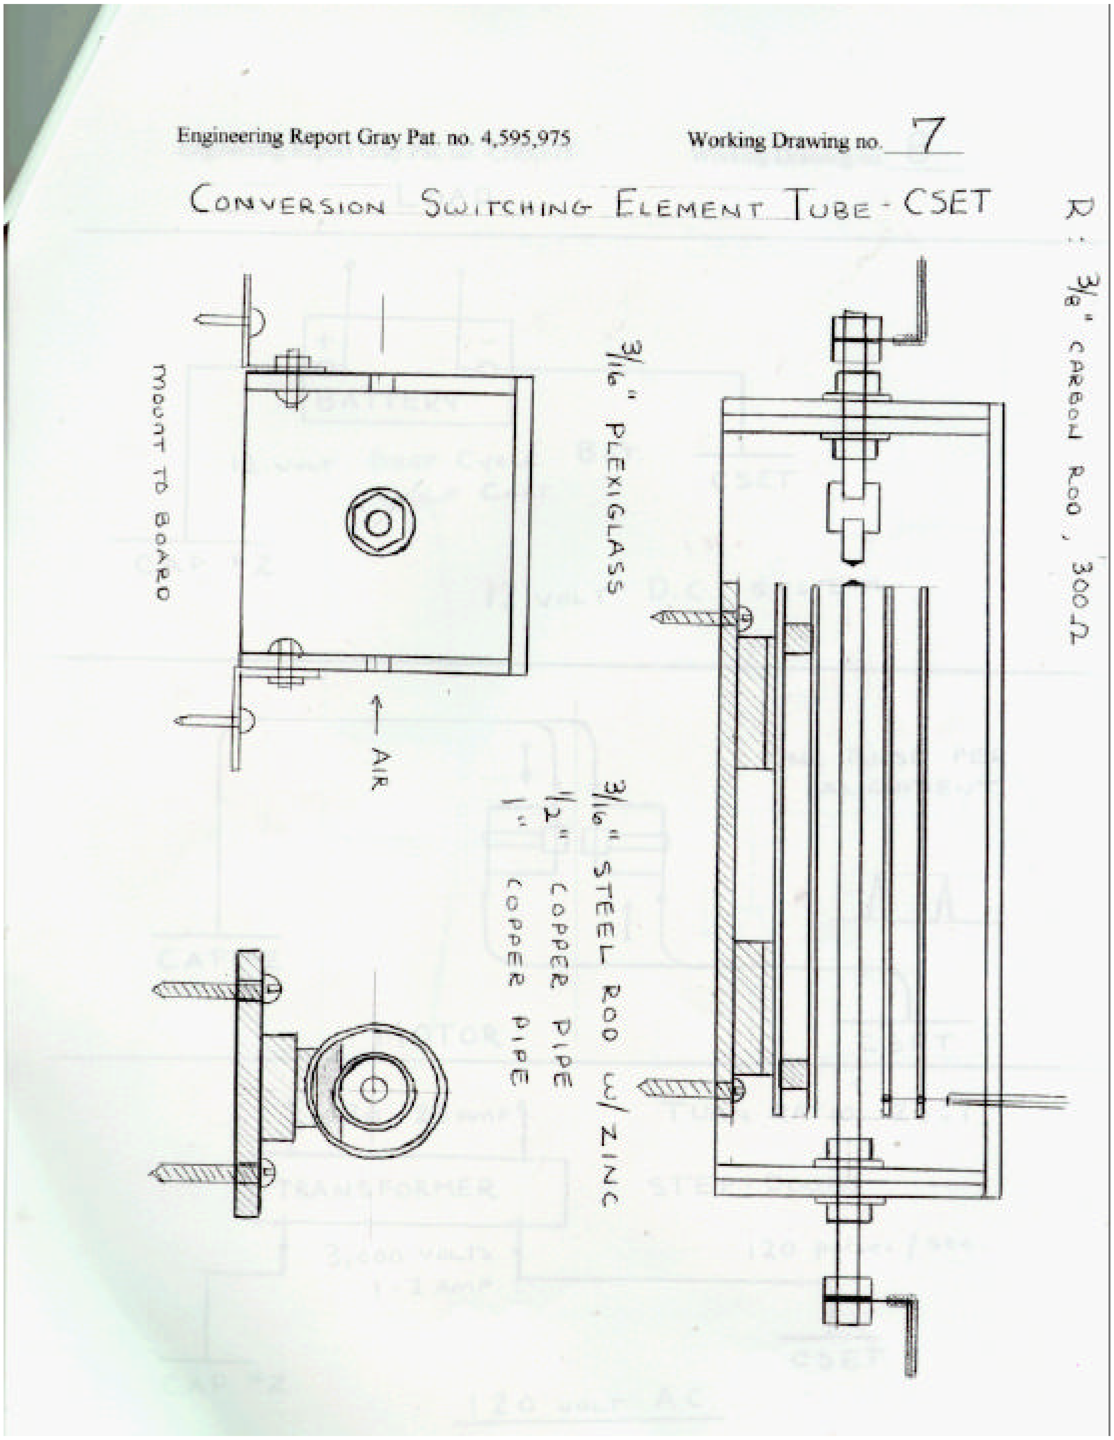
This switching circuit consist of a infared light emitting diode and a phototransistor.

They are positioned on the opposite sides of a revolving disk powered by a motor. Located on the disk are holes 318” in diameter equally positioned 30 degrees apart at a 4” radius on the disk. A motor rotates the disk at 1800 rpms (approximately). The holes on the disk allow the infared beam of light to trigger the base of the phototransistor. The diameter of the hole, the position on the disk and the rpm of the motor can be adjusted to create any pulsed DC



Engineering Report Gray Pat. no. 4,595,975 Working Drawing no. 7

CONVERSION SWITCHING ELEMENT TUBE - CSET

Circuit Section 7. Conversion Element Switching Tube. CSET

Before I explain the mechanics of the C SET, I would like to explain the principles that make the operation of the CSET possible. If we clearly understand how something works then the mechanics become very easy.

When the switch on the low voltage side of the CSET is open, the high voltage anode has a 3,000 volt positive potential. This draws electrons to the collector plates 34a and 3 4b.

When the switch is closed, current from the low voltage anode jumps the spark gap to the high voltage anode forming an ARC. An electric ARC does two things. First, it ionizes the air molecules to form positive and negative ions. Negative ions are free electrons. The high voltage positive potential anode picks up these free electrons. They are delivered to the negative terminal of the battery in the form of recharging pulses of power.

This gives the circuit a GAIN or increase in electrical energy. The second thing is absorbed by the collector plates in the CSET. This is called the photoelectric effect [see A. Einstein - photoelectric effect]. Quanta or photons of EMIR transfer their energy to the electrons in the copper collector plates. The pulse of EMR creates a pulse of electric power that travels across the collector plates to the wire terminal at the end of the plates. The wire transmits the power pulse to the load. At the same time, a BUNCH of electrons from the low voltage anode hit the high voltage anode and travel across the steel rod.

This negates the 3,000 volt positive potential on the high voltage anode thus repelling the electrons that were drawn to the collector plates. The combined effect is the creation of an instantaneous high-voltage, high-current energy pulse delivered to the LOAD.

The CSET requires AIR for the ionization of the atmosphere. Look at Gray’s motor patent and you will find that an air supply was delivered to insure proper conditions for arc-over.

In a technical discussion issued by Richard Hackenberger, Mr. Gray’s electrical engineer,

Mr. Hackenberger states that the disassociation of air molecules to form positive ions and negative ions is a key principle by which the gain in the circuit occurs. Quantum physics explains that when an electron is freed from its energy shell a quanta of EMR is released. [see Quantum Physics - Bohr I. It may be that the CSET was an vacuum tube.

The possibility will be included in future testing. All evidence points to the importance of AIR to form the ARC necessary to produce the EMR that induces the current in the collector plates.

The construction of the CSET is fairly simple. I consist of a plexiglass housing that allows air to reach the spark gap.

The high voltage anode and the low voltage anode are 3/16” steel rod, zinc plated. The collector plates are ½” by 4” copper pipe and I” by 4” copper pipe.

Spacers are scrap plexiglass held in place with super glue. I drilled holes in the collector grids. [

The collector grids may function better if there are no holes.}

The resistive element in the low voltage anode was not incorporated in the tests. I am going to include a resistive element made of 3/8” carbon rod as shown in the patent drawings of the CSET.

I am designing the resistive element for 300 ohms based on the assumption that there is 50 amps available from the positive terminal of the battery that can be drawn in a reverse current.

A 300 ohm resistor would limit the current to a 10 amp range. I am hoping that this will help bring the magnitude of the discharge into a containable range for the size of the CSET elements.

Circuit Section 8. Load

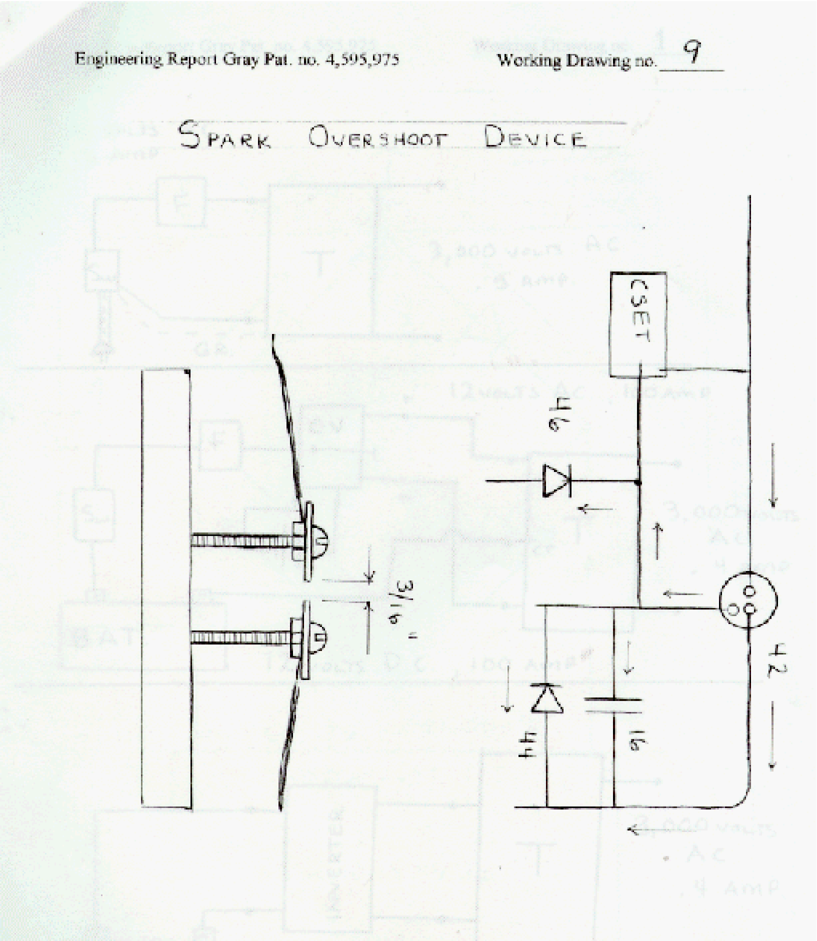
The Load or actually the means by which the Load (being the equipment to be powered by the circuit) is transferred is dependent upon the requirements of the equipment being powered. I would like to quote the Abstract from pat.4,595,975.

"When adapted to present day direct-current or alternating-current devices the LOAD could be a BATTERY or CAPACITOR to enhance the productivity of electrical energy."

Consider three different types of LOADS. A pulsed DC motor, a direct current circuit of 12 volts and an 110 AC circuit of lights or standard AC, 60 hertz equipment. In the case of a pulsed DC motor such as the one designed by Mr. Gray, one energy pulse repels like pole electromagnets arranged in a slightly offset manner.

Therefore the motor can be driven directly from the pulsed DC generated by the CSET if the pulse is timed with the alignment of the electromagnets. [please see motor patent,I]

If the Load is a 12 volt DC circuit, then a battery could be placed in circuit current energy spikes from the CSET to 110 volt, 120 pulses per sec may work. [haven’t tried it yet] I am trying to drive a motor I designed based upon Gray’s principles.



Circuit Section 9: Spark Overshoot Device

The spark overshoot device is a safety value for the CSET. If the energy pulse exceeds the design parameters of maximum allowable voltage, then arc over occurs and the excess energy is recycled back into the high-voltage circuit to be adsorbed by the capacitor #l and the battery. Spark gap is 3/16”, See Working Drawings.

Patent Rights:

Efficient Power Supply Suitable for Inductive Loads was patented by Mr. Edwin Gray in 1986. Mr. Gray passed away in 1989. Rumour has it [from his wife, he disappeared. To my knowledge he still holds the rights to the patent ? If you are interested in manufacturing this device you should try to seek permission from any controlling interest of the patent. We all are aware of the fact that we now stand at the edge of a world war and/or terrorist attacks motivated in part by the need for energy. It is definitely in the best interest of the United States of America to develop new energy sources as quickly as possible. Technological information travels so fast today that if we in the United States take a day off, an other country will bring this to market by tomorrow. 1 personally think that there is a social responsibility to bring this to market.

If someone does hold the patent rights, then it would seem that a fair and

June 17, 2003. Patent rights expire in 17 years unless other legal action is taken.

HIGH CURRENT DIODE: Mouser 1-800-346-6873
1000 N. Main Street, Mansfield TX 76063-15 14
part: 526-NTE6240 ultra fast, dual center tap, carbon cathode, 200 volt PIV, 20 amp forward current, 150 amp surge.
also (laser diode and photo transistor for laser switch- soon to be designed)

Resistor: 300 ohms - 3/8” carbon rod

Batteries: Deep Cycle Golf Cart

Low-Voltage Switching: motor with octagonal cam, automotive points, duration .0005 sec., 3600 rpm on motor - 120 pulses per Sec.

CSET: 3/16” plexiglass, 3/16” steel rod zinc plate, 3/16” spark gap, ½” by 4” copper pipe, U’ by 4” copper pipe, spacers- scrap plexiglass

CONCLUSION

This Engineering Report would never have been possible if it were not for the genius of Peter Lindemann,D. Sc.. His research connecting the work of Nicola Tesla and Edwin Gray is a brilliant contribution to the application of theoretical physics for the solution of world energy problems.

Those who break new ground are rarely acknowledged by the established scientific or higher education community until long after research becomes history. Kepler, Columbus, Einstien, Rutherford, Tesla, Gray and many others painfully encountered resistance to new research. The message here is not to be discouraged. If you know that the basic theory is correct, then never give up

To those of you who are doing scientific research on Gray's patents, congratulations, you are working on the actual generation of electrical power based on Quantum Physics. Here are some areas that need consideration;

BREMSSTRAIILUNG: “breaking radiation” The radiation emitted by electrons slowed down in matter. [free electrons entering a steel high-voltage anode] [Bunching]

PAIR PRODUCTION: The formation of a positron and an electron when electromagnetic energy interacts with matter.

PHOTOIONIZATION: The ionization of of a gas by light or other electromagnetic radiation; the photons must possess enough energy to detach one or more outer electrons from the gas atoms.

PHOTOCONDUCTION: The absorption of EMR by electrons in matter whereby the electrons are brought to the range of energy levels at which they move freely to conduct electricity.

BREAKDOWN: When electrons are accelerated to high velocity by the electric field at the [spark gap] and produce other free electrons by ionization collision with atoms. These free electrons are similarly accelerated by the field and in turn cause other ionizations. The avalanche process leads to a very large current.

Study the work of Tesla, Gray, Dr. Lindemann, Plank, Einstien and Bohr. Let us all work hard to make this technology available to everyone in a useful and constructive manner.

About the Author

Earl Boysen is an engineer who, after 20 years working in the computer chip industry, decided to slow down and move to a quiet town in the state of Washington. Boysen is the co-author of three other books: *Electronics for Dummies* (Indianapolis: Wiley, 2005), *Electronics Projects for Dummies* (Indianapolis: Wiley, 2006), and *Nanotechnology for Dummies* (Indianapolis: Wiley, 2005). He lives with his wife, Nancy, in a house they built together, and finds himself busy as ever writing books and running two technology-focused Web sites. His site, `www.BuildingGadgets.com`, focuses on electronics circuits and concepts. The other site, `www.understandingnano.com`, provides clear explanations of nanotechnology topics. Boysen holds a masters degree in Engineering Physics from the University of Virginia.

Acknowledgments

I want to first thank Harry Kybett for authoring the original version of this book many years ago. It was an honor to update such a classic book in the electronics field. Thanks also to Carol Long for bringing me on board with the project, and Kevin Shafer for his able project management of the book. My appreciation to Rex Miller for his excellent technical editing, and to Mildred Sanchez for handling all the mechanics of spelling and grammar in a thorough copy edit. Thanks to the people at Wiley, specifically Liz Britten for coordinating the creation of all the diagrams required and Eric Charbonneau for keeping the whole thing on schedule. Finally, thanks to my wife, Nancy Muir, for her advice and support throughout the writing of this book.

Introduction

The rapid growth of modern electronics is truly a phenomenon. All of the things you see in the marketplace today that utilize electronics either did not exist before 1960, or were crude by today's standards. Some of the many examples of modern electronics in the home include the small (but powerful) pocket calculator, the personal computer, the portable MP3 player, the DVD player, and digital cameras. Many industries have been founded, and older industries have been revamped, because of the availability and application of modern electronics in manufacturing processes, as well as in electronics products themselves.

Modern electronics *is* based on the transistor and its offspring — the integrated circuit (IC) and the microprocessor. These have short-circuited much of traditional electronic theory, revolutionized its practice, and set the whole field off on several new paths of discovery. This book is a first step to help you begin your journey down those paths.

What This Book Teaches

The traditional way of teaching electronics is often confusing. Too many students are left feeling that the real core of electronics is mysterious and arcane, akin to black magic. This just is not so. In fact, while many areas of our lives have become almost unbelievably complex, the study and practice of electronics in industry and as a hobby has surprisingly been made much simpler. *All New Electronics Self-Teaching Guide, Third Edition*, takes advantage of this simplicity and covers only those areas you actually need in modern electronics.

This book is for anyone who has a basic understanding of electronics concepts, but who wants to understand the operation of components found in the most common discrete circuits. The chapters in this book focus on circuits that are the building blocks for many common electronics devices, and on the very few important principles you need in working with electronics.

The arrangement and approach of this book is completely different from any other book on electronics in that it uses a ‘‘question-and-answer’’ approach to lead you into simple, but pertinent, experiments. This book steps you through calculations for every example in an easy-to-understand fashion, and you do not need to have a mathematical background beyond first-year algebra to follow along. In addition, this book omits the usual chapters on semiconductor physics, because you don’t need these in the early stages of working with electronics.

Electronics is a very easy technology, which anyone can understand with very little effort. This book focuses on how to apply the few basic principles that are the basis of modern electronic practice. Understanding the circuits composed of discrete components and the applicable calculations discussed in this book is useful not only in building and designing circuits, but it also helps you to work with ICs. That’s because ICs use miniaturized components such as transistors, diodes, capacitors, and resistors that function based on the same rules as discrete components (along with some specific rules necessitated by the extremely small size of IC components).

How This Book Is Organized

This book is organized with sets of problems that challenge you to think through a concept or procedure, and then provides answers so you can constantly check your progress and understanding. Specifically, the chapters in this book are organized as follows:

- *Chapter* 1: *DC Review and Pre-Test* — This chapter provides a review and pre-test on the basic concepts, components, and calculations that are useful when working with direct current (DC) circuits.
- *Chapter* 2: *The Diode* — Here you learn about the diode, including how you use diodes in DC circuits, the main characteristics of diodes, and calculations you can use to determine current, voltage, and power.
- *Chapter* 3: *Introduction to the Transistor* — In this chapter, you learn about the transistor and its use in circuits. You also discover how bipolar junction transistors (BJTs) and junction field effect transistors (JFETs) control the flow of electric current.

- *Chapter* 4: *The Transistor Switch* — This chapter examines the most simple and widespread application of a transistor: switching. In addition to learning how to design a transistor circuit to drive a particular load, you also compare the switching action of a JFET and a BJT.
- *Chapter* 5: *AC Pre-Test and Review* — This chapter examines the basic concepts and equations for alternating current (AC) circuits. You discover how to use resistors and capacitors in AC circuits, and learn related calculations.
- *Chapter* 6: *AC in Electronics* — This chapter looks at how resistors, capacitors, and inductors are used in high pass filters and low pass filters to pass or block AC signals above or below a certain frequency.
- *Chapter* 7: *Resonant Circuits* — This chapter examines the use of capacitors, inductors, and resistors in circuits called bandpass filters and band-reject filters, which pass or block AC signals in a band of frequencies centered around the resonant frequency of the circuit. You also learn how to calculate the resonance frequency and bandwidth of these circuits. This chapter also introduces you to how to use resonant circuits in oscillators.
- *Chapter* 8: *Transistor Amplifiers* — Here you explore the use of transistor amplifiers to amplify electrical signals. In addition to examining the fundamental steps used to design BJT-based amplifiers, you learn how to use JFETs and operational amplifiers (op-amps) in amplifier circuits.
- *Chapter* 9: *Oscillators* — This chapter introduces you to the oscillator, a circuit that produces a continuous AC output signal. You learn how an oscillator works, and step through the procedure to design and build an oscillator.
- *Chapter* 10: *The Transformer* — In this chapter, you discover how AC voltage is converted by a transformer to a higher or lower voltage. You learn how a transformer makes this conversion, and how to calculate the output voltage that results.
- *Chapter* 11: *Power Supply Circuits* — In this chapter, you find out how power supplies convert AC to DC with a circuit made up of transformers, diodes, capacitors, and resistors. You also learn how to calculate the values of components that produce a specified DC output voltage for a power supply circuit.
- *Chapter* 12: *Conclusion and Final Self-Test* — This chapter enables you to check your understanding of the topics presented in this book through the use of a final self-test that allows you to assess your overall knowledge of electronics.

In addition, this book contains the following appendixes for easy reference:

- *Appendix A: Glossary* — This glossary provides key electronics terms and their definitions.
- *Appendix B: List of Symbols and Abbreviations* — This appendix provides a handy reference of commonly used symbols and abbreviations.
- *Appendix C: Powers of Ten and Engineering Prefixes* — This guide lists prefixes that are commonly used in electronics, along with their corresponding values.
- *Appendix D: Standard Composition Resistor Values* — This appendix provides standard resistance values for the carbon composition resistor, the most commonly used type of resistor.
- *Appendix E: Supplemental Resources* — This appendix provides references to helpful Web sites, books, and magazines.
- *Appendix F: Equation Reference* — This is a quick guide to commonly used equations, along with chapter and problem references showing you where they are first introduced in this book.
- *Appendix G: Schematic Symbols Used in This Book* — This appendix provides a quick guide to schematic symbols used in the problems found throughout the book.

Conventions Used In This Book

As you study electronics you will find that there is some variation in terminology and the way that circuits are drawn. Here are two conventions followed in this book that you should be aware of:

- The discussions in this book use V to stand for voltage, versus E, which you will see used in some other books.
- In all circuit diagrams in this book, intersecting lines indicate an electrical connection. (Some other books use a dot at the intersection of lines to indicate a connection.) If a semicircle appears at the intersection of two lines, it indicates that there is no connection. See Figure 9.5 for an example of this.

How to Use This Book

This book assumes that you have some knowledge of basic electronics such as Ohm's law and current flow. If you have read a textbook or taken a course on electronics, or if you have worked with electronics, you probably have the prerequisite knowledge. If not, you should read a book such as *Electronics for Dummies* (Indianapolis: Wiley, 2005) to get the necessary background for this book. You can also go to the author's Web site, `www.BuildingGadgets.com`, and use the Tutorial links to find useful online lessons in electronics. In addition, Chapters 1 and 5 allow you to test your knowledge and review the necessary basics of electronics.

Note that you should read the chapters in order, because often later material depends on concepts and skills covered in earlier chapters.

All New Electronics Self-Teaching Guide, Third Edition, is presented in a self-teaching format that allows you to learn easily and at your own pace. The material is presented in numbered sections called *problems*. Each problem presents some new information and gives you a question to answer, or an experiment to try. To learn most effectively, you should cover up the answers with a sheet of paper and try to answer each question on your own. Then, compare your answer with the correct answer that follows. If you miss a question, correct your answer and then go on. If you miss many in a row, go back and review the previous section, or you may miss the point of the material that follows.

Be sure to try to do all of the experiments. They are very easy and help reinforce your learning of the subject matter. If you don't have the equipment to do an experiment, simply reading through it will help you to better understand the concepts it demonstrates.

When you reach the end of a chapter, evaluate your learning by taking the Self-Test. If you miss any questions, review the related parts of the chapter again. If you do well on the Self-Test, you're ready to go on to the next chapter. You may also find the Self-Test useful as a review before you start the next chapter. At the end of the book, there is a Final Self-Test that allows you to assess your overall learning.

Go through this book at your own pace. You can work through this book alone, or you can use it in conjunction with a course. If you use the book alone, it serves as an introduction to electronics, but is not a complete course. For that reason, at the end of the book are some suggestions for further reading and online resources. Also, at the back of the book is a table of symbols and abbreviations, which are useful for reference and review.

Now you're ready to learn *electronics*!

CHAPTER

1

DC Review and Pre-Test

Electronics cannot be studied without first understanding the basics of electricity. This chapter is a review and pre-test on those aspects of direct current (DC) that apply to electronics. By no means does it cover the whole DC theory, but merely those topics that are essential to simple electronics. This chapter will review the following:

- Current flow
- Potential or voltage difference
- Ohm's law
- Resistors in series and parallel
- Power
- Small currents
- Resistance graphs
- Kirchhoff's voltage and current laws
- Voltage and current dividers
- Switches
- Capacitor charging and discharging
- Capacitors in series and parallel

Current Flow

1 Electrical and electronic devices work because of an electric current.

Question

What is an electric current?

____

Answer

An electric current is a flow of electric charge. The electric charge usually consists of negatively charged electrons. However, in semiconductors, there are also positive charge carriers called *holes*.

2 There are several methods that can be used to generate an electric current.

Question

Write at least three ways an electron flow (or current) can be generated.

____

____

____

Answers

The following is a list of the most common ways to generate current:

Magnetically — The induction of electrons in a wire rotating within a magnetic field. An example of this would be generators turned by water, wind, or steam, or the fan belt in a car.

Chemically — Involving electrochemical generation of electrons by reactions between chemicals and electrodes (as in batteries).

Photovoltaic generation of electrons — When light strikes semiconductor crystals (as in solar cells).

Less common methods to generate an electric current include the following:

Thermal generation — Using temperature differences between thermocouple junctions. Thermal generation is used in generators on spacecraft that are fueled by radioactive material.

Electrochemical reaction — Occurring between hydrogen, oxygen, and electrodes (fuel cells).

Piezoelectrical — Involving mechanical deformation of piezoelectric substances. For example, piezoelectric material in the heels of shoes power LEDs that light up when you walk.

3 Most of the simple examples in this book will contain a battery as the voltage source. As such, the source provides a potential difference to a circuit that will enable a current to flow. An *electric current* is a flow of electric charge. In the case of a battery, electrons are the electric charge, and they flow from the terminal that has an excess number of electrons to the terminal that has a deficiency of electrons. This flow takes place in any complete circuit that is connected to battery terminals. It is this difference of charge that creates the potential difference in the battery. The electrons are trying to balance the difference.

Because electrons have a negative charge, they actually flow from the negative terminal and return to the positive terminal. We call this direction of flow *electron flow*. Most books, however, use current flow, which is in the opposite direction. It is referred to as *conventional current flow* or simply *current flow*. In this book, the term conventional current flow is used in all circuits.

Later in this book, you will see that many semiconductor devices have a symbol that contains an arrowhead pointing in the direction of conventional current flow.

Questions

A. Draw arrows to show the current flow in Figure 1-1. The symbol for the battery shows its polarity.

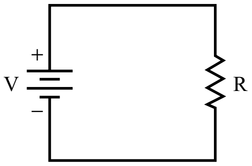

Figure 1-1

B. What indicates that a potential difference is present?

____

C. What does the potential difference cause?

____

D. What will happen if the battery is reversed?

____

Answers

A. See Figure 1-2.

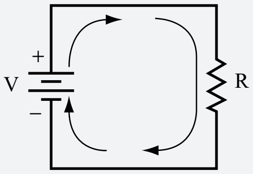

Figure 1-2

B. The battery symbol indicates that a difference of potential, also called *voltage*, is being supplied to the circuit.

C. Voltage causes current to flow if there is a complete circuit present, as shown in Figure 1-1.

D. The current will flow in the opposite direction.

Ohm's Law

4 Ohm's law states the fundamental relationship between voltage, current, and resistance.

Question

What is the algebraic formula for Ohm's law?

Answer

$V = I \times R$

This is the most basic equation in electricity, and you should know it well. Note that some electronics books state Ohm's law as $E = IR$. E and V are both symbols for voltage. This book uses V throughout. Also, in this formula, resistance is the opposition to current flow. Note that larger resistance results in smaller current for any given voltage.

5 Use Ohm's law to find the answers in this problem.

Questions

What is the voltage for each combination of resistance and current values?

A. R = 20 ohms I = 0.5 amperes V = ____________

B. R = 560 ohms I = 0.02 amperes V = ____________

C. R = 1000 ohms I = 0.01 amperes V = ____________

D. R = 20 ohms I = 1.5 amperes V = ____________

Answers

A. 10 volts

B. 11.2 volts

C. 10 volts

D. 30 volts

6 You can rearrange Ohm's law to calculate current values.

Questions

What is the current for each combination of voltage and resistance values?

A. V = 1 volt R = 2 ohms I = ____________

B. V = 2 volts R = 10 ohms I = ____________

C. V = 10 volts R = 3 ohms I = ____________

D. V = 120 volts R = 100 ohms I = ____________

Answers

A. 0.5 amperes

B. 0.2 amperes

C. 3.3 amperes

D. 1.2 amperes

7 You can rearrange Ohm's law to calculate resistance values.

Questions

What is the resistance for each combination of voltage and current values?

A. V = 1 volt I = 1 ampere R = ____________

B. V = 2 volts I = 0.5 ampere R = ____________

C. V = 10 volts I = 3 amperes R = ____________

D. V = 50 volts I = 20 amperes R = ____________

Answers

A. 1 ohm

B. 4 ohms

C. 3.3 ohms

D. 2.5 ohms

8 Work through these examples. In each case, two factors are given and you must find the third.

Questions

What are the missing values?

A. 12 volts and 10 ohms. Find the current.

____

B. 24 volts and 8 amperes. Find the resistance.

____

C. 5 amperes and 75 ohms. Find the voltage.

____

Answers

A. 1.2 amperes

B. 3 ohms

C. 375 volts

Resistors in Series

9 Resistors can be connected in series. Figure 1-3 shows two resistors in series.

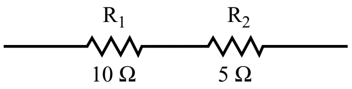

Figure 1-3

Question

What is their total resistance?

Answer

$R_T = R_1 + R_2 = 10$ ohms $+ 5$ ohms $= 15$ ohms

The total resistance is often called the *equivalent series resistance*, and is denoted as R_{eq}.

Resistors in Parallel

10 Resistors can be connected in parallel, as shown in Figure 1-4.

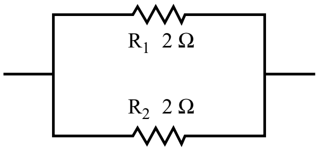

Figure 1-4

Question

What is the total resistance here?

Answer

$$\frac{1}{R_T} = \frac{1}{R_1} + \frac{1}{R_2} = \frac{1}{2} + \frac{1}{2} = 1;\ \text{thus } R_T = 1 \text{ ohm}$$

R_T is often called the *equivalent parallel resistance*.

11 The simple formula from problem 10 can be extended to include as many resistors as desired.

Question

What is the formula for three resistors in parallel?

Answer

$$\frac{1}{R_T} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3}$$

You will often see this formula in the following form:

$$R_T = \frac{1}{\frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3}}$$

12 In the following exercises, two resistors are connected in parallel.

Questions

What is the total or equivalent resistance?

A. $R_1 = 1$ ohm $R_2 = 1$ ohm $R_T =$ ____________

B. $R_1 = 1000$ ohms $R_2 = 500$ ohms $R_T =$ ____________

C. $R_1 = 3600$ ohms $R_2 = 1800$ ohms $R_T =$ ____________

Answers

A. 0.5 ohms

B. 333 ohms

C. 1200 ohms

Note that R_T is always smaller than the smallest of the resistors in parallel.

Power

13 When current flows through a resistor, it dissipates power, usually in the form of heat. Power is expressed in terms of watts.

Question

What is the formula for power?

____

Answer

There are three formulas for calculating power:

$$P = VI \text{ or } P = I^2R \text{ or } P = \frac{V^2}{R}$$

14 The first formula shown in problem 13 allows power to be calculated when only the voltage and current are known.

Questions

What is the power dissipated by a resistor for the following voltage and current values?

A. $V = 10$ volts $I = 3$ amperes $P =$ ______________

B. $V = 100$ volts $I = 5$ amperes $P =$ ______________

C. $V = 120$ volts $I = 10$ amperes $P =$ ______________

Answers

A. 30 watts

B. 500 watts, or 0.5 kilowatts

C. 1200 watts, or 1.2 kilowatts

15 The second formula shown in problem 13 allows power to be calculated when only the current and resistance are known.

Questions

What is the power dissipated by a resistor given the following resistance and current values?

A. $R = 20$ ohm $I = 0.5$ ampere $P =$ ______________

B. $R = 560$ ohms $I = 0.02$ ampere $P =$ ______________

C. $V = 1$ volt $R = 2$ ohms $P =$ ______________

D. $V = 2$ volt $R = 10$ ohms $P =$ ______________

Answers

A. 5 watts

B. 0.224 watts

C. 0.5 watts

D. 0.4 watts

16 Resistors used in electronics generally are manufactured in standard values with regard to resistance and power rating. Appendix D shows a table of standard resistance values. Quite often, when a certain resistance value is needed in a circuit, you must choose the closest standard value. This is the case in several examples in this book.

You must also choose a resistor with the power rating in mind. You should never place a resistor in a circuit that would require that resistor to dissipate more power than its rating specifies.

Questions

If standard power ratings for carbon composition resistors are 1/4, 1/2, 1, and 2 watts, what power ratings should be selected for the resistors that were used for the calculations in problem 15?

A. For 5 watts________________

B. For 0.224 watts_____________

C. For 0.5 watts_______________

D. For 0.4 watts_______________

Answers

A. 5 watt (or greater)

B. 1/4 watt (or greater)

C. 1/2 watt (or greater)

D. 1/2 watt (or greater)

Most electronics circuits use low power carbon composition resistors. For higher power levels (such as the 5 watt requirement in question A), other types of resistors are available.

Small Currents

17 Although currents much larger than 1 ampere are used in heavy industrial equipment, in most electronic circuits, only fractions of an ampere are required.

Questions

A. What is the meaning of the term *milliampere*?

____

B. What does the term *microampere* mean?

____

Answers

A. A milliampere is one-thousandth of an ampere (that is, 1/1000 or 0.001 amperes). It is abbreviated mA.

B. A microampere is one-millionth of an ampere (that is, 1/1,000,000 or 0.000001 amperes). It is abbreviated μA.

18 In electronics, the values of resistance normally encountered are quite high. Often, thousands of ohms and occasionally even millions of ohms are used.

Questions

A. What does kΩ mean when it refers to a resistor?

____

B. What does MΩ mean when it refers to a resistor?

____

Answers

A. Kilohm (k = kilo, Ω = ohm). The resistance value is thousands of ohms. Thus, 1 kΩ = 1,000 ohms, 2 kΩ = 2,000 ohms, and 5.6 kΩ = 5,600 ohms.

B. Megohm (M = mega, Ω = ohm). The resistance value is millions of ohms. Thus, 1 MΩ = 1,000,000 ohms, and 2.2 MΩ = 2,200,000 ohms.

19 The following exercise is typical of many performed in transistor circuits. In this example, 6 V is applied across a resistor and 5 mA of current is required to flow through the resistor.

Question

What value of resistance must be used and what power will it dissipate?

R = ______________ P = ______________

Answer

$$R = \frac{V}{I} = \frac{6\text{ V}}{5\text{ mA}} = \frac{6}{0.005} = 1200\text{ ohms} = 1.2\text{ k}\Omega$$

$$P = V \times I = 6 \times 0.005 = 0.030\text{ watts} = 30\text{ mW}$$

20 Now, try these two simple examples.

Questions

What is the missing value?

A. 50 volts and 10 mA. Find the resistance.

____

B. 1 volt and 1 MΩ. Find the current.

____

Answers

A. 5 kΩ

B. 1 μA

The Graph of Resistance

21 The voltage drop across a resistor and the current flowing through it can be plotted on a simple graph. This graph is called a *V-I curve*.

Consider a simple circuit in which a battery is connected across a 1 kΩ resistor.

Questions

A. Find the current flowing if a 10 V battery is used.

____

B. Find the current when a 1 V battery is used.

____

C. Now find the current when a 20 V battery is used.

____

Answers

A. 10 mA

B. 1 mA

C. 20 mA

22 Plot the points of battery voltage and current flow from problem 21 on the graph shown in Figure 1-5, and connect them together.

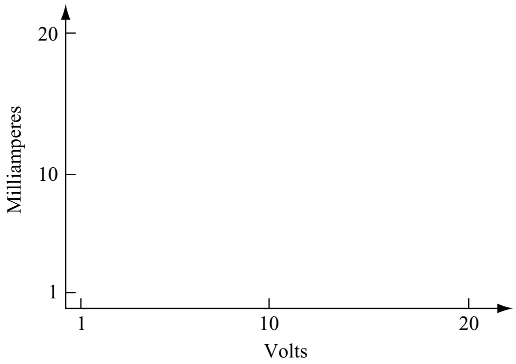

Figure 1-5

Answer

You should have drawn a straight line, as in the graph shown in Figure 1-6.

Sometimes you need to calculate the slope of the line on a graph. To do this, pick two points and call them A and B.

For point A let V = 5 volts and I = 5 mA

For point B let V = 20 volts and I = 20 mA

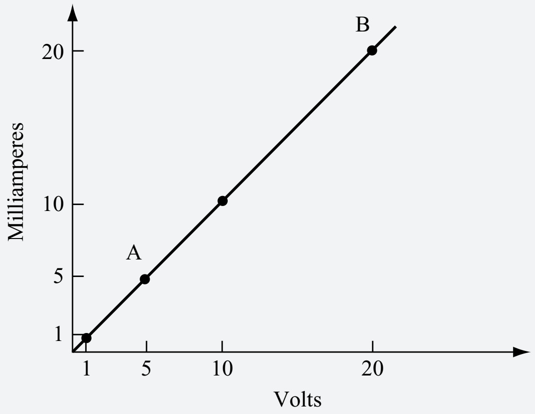

Figure 1-6

The slope can be calculated with the following formula:

$$\text{Slope} = \frac{V_B - V_A}{I_B - I_A} = \frac{20\text{ volts} - 5\text{ volts}}{20\text{ mA} - 5\text{ mA}} = \frac{15\text{ volts}}{15\text{ mA}} = \frac{15\text{ volts}}{0.015\text{ A}} = 1\text{ k}\Omega$$

In other words, the slope of the line is equal to the resistance.

Later, you will learn about V-I curves for other components. They have several uses, and often they are not straight lines.

The Voltage Divider

23 The circuit shown in Figure 1-7 is called a *voltage divider*. It is the basis for many important theoretical and practical ideas you encounter throughout the entire field of electronics.

The object of this circuit is to create an output voltage (V_0) that you can control based upon the two resistors and the input voltage. Note that V_0 is also the *voltage drop* across R_2.

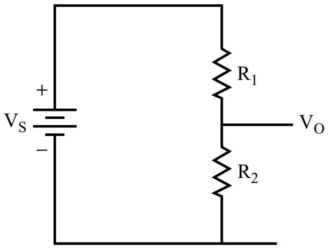

Figure 1-7

Question

What is the formula for V_0?

Answer

$$V_o = V_S \times \frac{R_2}{R_1 + R_2}$$

Note that $R_1 + R_2 = R_T$, the total resistance of the circuit.

24 A simple example will demonstrate the use of this formula.

Question

For the circuit shown in Figure 1-8, what is V_0?

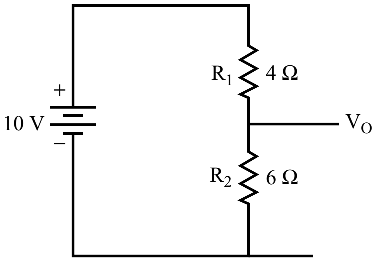

Figure 1-8

Answer

$$\begin{aligned} V_O &= V_S \times \frac{R_2}{R_1 + R_2} \\ &= 10 \times \frac{6}{4+6} \\ &= 10 \times \frac{6}{10} \\ &= 6 \text{ volts} \end{aligned}$$

25 Now, try these problems.

Questions

What is the output voltage for each combination of supply voltage and resistance?

A. $V_S = 1$ volt $R_1 = 1$ ohm $R_2 = 1$ ohm $V_0 =$ ______________

B. $V_S = 6$ volts $R_1 = 4$ ohms $R_2 = 2$ ohms $V_0 =$ ______________

C. $V_S = 10$ volts $R_1 = 3.3$ kΩ $R_2 = 5.6$ kΩ $V_0 =$ ______________

D. $V_S = 28$ volts $R_1 = 22$ kΩ $R_2 = 6.2$ kΩ $V_0 =$ ______________

Answers

A. 0.5 volts

B. 2 volts

C. 6.3 volts

D. 6.16 volts

26 The output voltage from the voltage divider is always less than the applied voltage. Voltage dividers are often used to apply specific voltages to different components in a circuit. Use the voltage divider equation to answer the following questions.

Questions

A. What is the voltage drop across the 22k resistor for question D of problem 25?

____

B. What total voltage do you get if you add this voltage drop to the voltage drop across the 6.2k resistor?

____

Answers

A. 21.84 volts

B. The sum is 28 volts.

Note that the voltages across the two resistors add up to the supply voltage. This is an example of Kirchhoff's voltage law (KVL), which simply means that the voltage supplied to a circuit must equal the sum of the voltage drops in the circuit. In this book, KVL will often be used without actual reference to the law.

Also notice that voltage drop across a resistor is proportional to the resistor's value. Therefore, if one resistor has a greater value than another in a series circuit, the voltage drop across the higher value resistor will be greater.

The Current Divider

27 In the circuit shown in Figure 1-9, the current splits or divides between the two resistors that are connected in parallel.

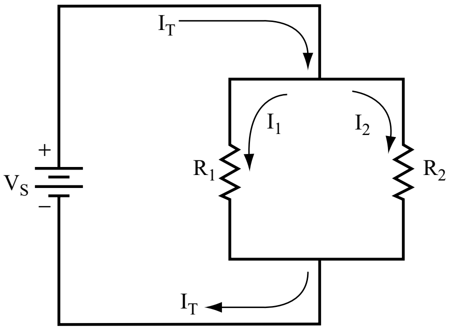

Figure 1-9

I_T splits into the individual currents I_1 and I_2, and then these recombine to form I_T.

Question

Which of the following relationships are valid for this circuit?

A. $V_S = R_1I_1$

B. $V_S = R_2I_2$

C. $R_1I_1 = R_2I_2$

D. $I_1/I_2 = R_2/R_1$

Answer

All of them are valid.

28 When solving current divider problems, follow these steps:

1. Set up the ratio of the resistors and currents.

   $I_1/I_2 = R_2/R_1$

2. Rearrange the ratio to give I_2 in terms of I_1:

   $$I_2 = I_1 \times \frac{R_1}{R_2}$$

3. From the fact that $I_T = I_1 + I_2$, express I_T in terms of I_1 only.
4. Now, find I_1.
5. Now, find the remaining current (I_2).

Question

The values of two resistors in parallel and the total current flowing through the circuit are shown in Figure 1-10. What is the current through each individual resistor?

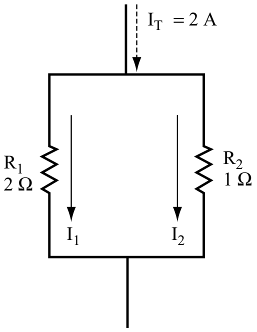

Figure 1-10

Answers

Working through the steps as shown:

1. $I_1/I_2 = R_2/R_1 = 1/2$
2. $I_2 = 2I_1$
3. $I_T = I_1 + I_2 = I_1 + 2I_1 = 3I_1$
4. $I_1 = I_T/3 = 2/3\ \text{A}$
5. $I_2 = 2I_1 = 4/3\ \text{A}$

29 Now, try these problems. In each case, the total current and the two resistors are given. Find I_1 and I_2.

Questions

A. $I_T = 30\ mA$, $R_1 = 12\ k\Omega$, $R_2 = 6\ k\Omega$

B. $I_T = 133\ mA$, $R_1 = 1\ k\Omega$, $R_2 = 3\ k\Omega$

C. What current do you get if you add I_1 and I_2?

Answers

A. $I_1 = 10\ mA$, $I_2 = 20\ mA$

B. $I_1 = 100\ mA$, $I_2 = 33\ mA$

C. They add back together to give you the total current supplied to the parallel circuit.

Note that question C is actually a demonstration of Kirchhoff's current law (KCL). This law simply stated says that the total current entering a junction in a circuit must equal the sum of the currents leaving that junction. This law will also be used on numerous occasions in later chapters. KVL and KCL together form the basis for many techniques and methods of analysis that are used in the application of circuit analysis.

Also, notice that the current through a resistor is inversely proportional to the resistor's value. Therefore, if one resistor is larger than another in a parallel circuit, the current flowing through the higher value resistor will be the smaller of the two. Check your results for this problem to verify this.

30 You can also use the following equation to calculate the current flowing through a resistor in a two-branch parallel circuit:

$$I_1 = \frac{(I_T)(R_2)}{(R_1 + R_2)}$$

Question

Write the equation for the current I_2.

Check the answers for the previous problem using these equations.

Answer

$$I_2 = \frac{(I_T)(R_1)}{(R_1 + R_2)}$$

Note that the current through one branch of a two-branch circuit is equal to the total current times the resistance of the opposite branch, divided by the sum of the resistances of both branches. This is an easy formula to remember.

Switches

31 A *mechanical switch* is a device that completes or breaks a circuit. The most familiar use is that of applying power to turn a device on or off. A switch can also permit a signal to pass from one place to another, prevent its passage, or route a signal to one of several places.

In this book we deal with two types of switches. The first is the simple on-off switch, also called a *single pole single throw* switch. The second is the *single pole double throw* switch. The circuit symbols for each are shown in Figure 1-11.

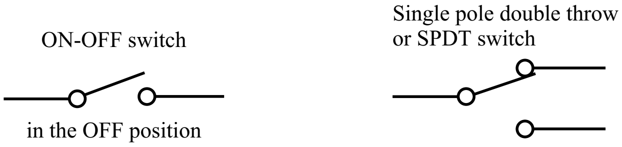

Figure 1-11

Two important facts about switches must be known.

- A closed (or ON) switch has the total circuit current flowing through it. There is *no* voltage drop across its terminals.
- An open (or OFF) switch has *no* current flowing through it. The full circuit voltage appears between its terminals.

The circuit shown in Figure 1-12 includes a closed switch.

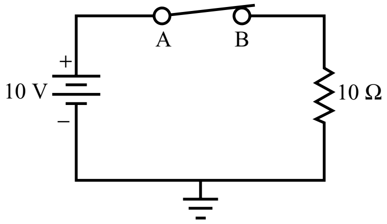

Figure 1-12

Questions

A. What is the current flowing through the switch?

____

B. What is the voltage at point A and point B with respect to ground?

____

C. What is the voltage drop across the switch?

____

Answers

A. $\frac{10 \text{ V}}{10 \text{ ohms}} = 1$ ampere

B. $V_A = V_B = 10$ V

C. 0 V (There is no voltage drop because both terminals are at the same voltage.)

32 The circuit shown in Figure 1-13 includes an open switch.

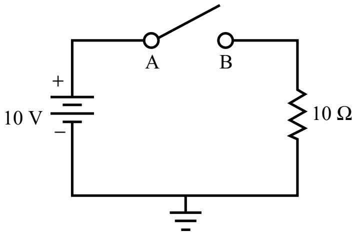

Figure 1-13

Questions

A. What is the voltage at point A and point B?

____

B. How much current is flowing through the switch?

____

C. What is the voltage drop across the switch?

____

Answers

A. $V_A = 10$ V; $V_B = 0$ V

B. No current is flowing because the switch is open.

C. 10 V. If the switch is open, point A is the same voltage as the positive battery terminal and point B is the same voltage as the negative battery terminal.

33 The circuit shown in Figure 1-14 includes a single pole double throw switch. The position of the switch determines whether lamp A or lamp B is lit.

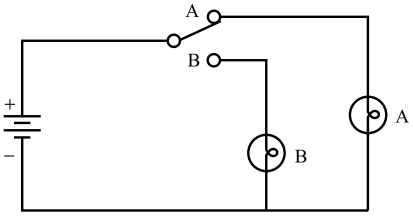

Figure 1-14

Questions

A. In the position shown, which lamp is lit?

B. Can both lamps be lit simultaneously?

Answers

A. Lamp A.

B. No, one or the other must be off.

Capacitors in a DC Circuit

34 Capacitors are used extensively in electronics. They are used in both alternating current (AC) and DC circuits. Their main use in DC electronics is to become charged, hold the charge, and, at a specific time, release the charge.

The capacitor shown in Figure 1-15 charges when the switch is closed.

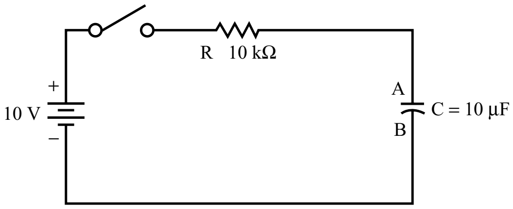

Figure 1-15

Question

To what final voltage will the capacitor charge?

Answer

It will charge up to 10 V. It will charge up to the voltage that would appear across an open circuit located at the same place where the capacitor is located.

35 How long does it take to reach this voltage? This is a most important question, with many practical applications. To find the answer you have to know the *time constant* (τ) of the circuit.

Questions

A. What is the formula for the time constant of this type of circuit?

B. What is the time constant for the circuit shown in Figure 1-15?

C. How long does it take the capacitor to reach 10 V?

D. To what voltage level does it charge in one time constant?

Answers

A. $\tau = R \times C$

B. $\tau = 10\ \text{k}\Omega \times 10\ \mu\text{F} = 10{,}000\ \Omega \times 0.00001\ \text{F} = 0.1$ seconds. (Convert resistance values to ohms and capacitance values to farads for this calculation.)

C. Approximately 5 time constants, or about 0.5 seconds.

D. 63 percent of the final voltage, or about 6.3 V.

36 The capacitor will not begin charging until the switch is closed. When a capacitor is uncharged or discharged, it has the same voltage on both plates.

Questions

A. What will be the voltage on plate A and plate B of the capacitor in Figure 1-15 before the switch is closed?

B. When the switch is closed, what will happen to the voltage on plate A?

C. What will happen to the voltage on plate B?

D. What will be the voltage on plate A after one time constant?

Answers

A. Both will be at 0 V if the capacitor is totally discharged.

B. It will rise towards 10 V.

C. It will stay at 0 V.

D. About 6.3 V.

37 The *capacitor charging graph* in Figure 1-16 shows for how many time constants a voltage must be applied to a capacitor before it reaches a given percentage of the applied voltage.

Questions

A. What is this type of curve called?

B. What is it used for?

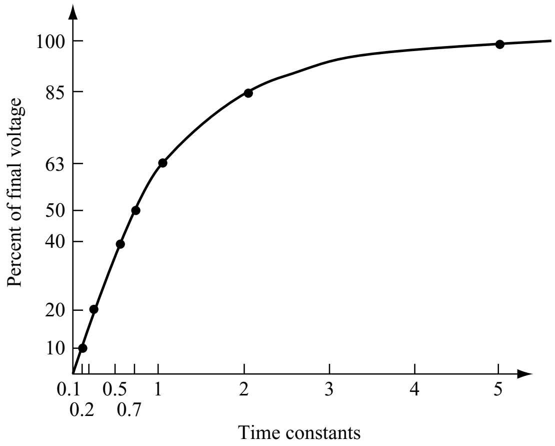

Figure 1-16

Answers

A. It is called an *exponential* curve.

B. It is used to calculate how far a capacitor has charged in a given time.

38 In the following, examples a resistor and a capacitor are in series. Calculate the time constant, how long it takes the capacitor to fully charge, and the voltage level after one time constant if a 10 V battery is used.

Questions

A. R = 1 kΩ C = 1000 μF

B. R = 330 kΩ C = 0.05 μF

Answers

A. $\tau = 1$ second; charge time = 5 seconds; $V_C = 6.3$ V

B. $\tau = 16.5$ ms; charge time = 82.5 ms; $V_C = 6.3$ V (The abbreviation ms indicates milliseconds.)

39 The circuit shown in Figure 1-17 uses a double pole switch to create a discharge path for the capacitor.

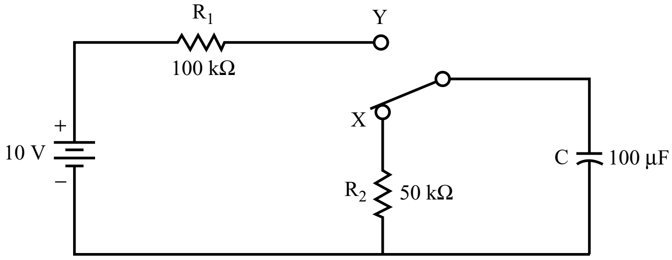

Figure 1-17

Questions

A. With the switch in position X, what is the voltage on each plate of the capacitor?

B. When the switch is moved to position Y, the capacitor begins to charge. What is its charging time constant?

C. How long does it take to fully charge the capacitor?

Answers

A. 0 V

B. $\tau = R \times C = (100\ k\Omega)\ (100\ \mu F) = 10$ secs

C. Approximately 50 seconds

40 Suppose that the switch shown in Figure 1-17 is moved back to position X once the capacitor is fully charged.

Questions

A. What is the discharge time constant of the capacitor?

B. How long does it take to fully discharge the capacitor?

Answers

A. $\tau = R \times C = (50\ k\Omega)\ (100\ \mu F) = 5$ seconds (discharging through the 50 kΩ resistor)

B. Approximately 25 seconds

The circuit powering a camera flash is an example of a capacitor's ability to store charge and then discharge upon demand. While you wait for the flash unit to charge, the camera is using its battery to charge a capacitor. Once the capacitor is charged, it holds that charge until you click the shutter button, causing the capacitor to discharge, which powers the flash.

41 Capacitors can be connected in parallel, as shown in Figure 1-18.

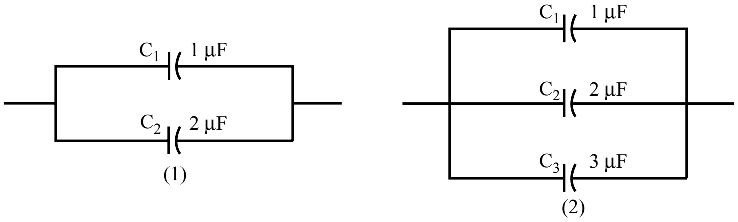

Figure 1-18

Questions

A. What is the formula for the total capacitance?

____

B. What is the total capacitance in circuit 1?

____

C. What is the total capacitance in circuit 2?

____

Answers

A. $C_T = C_1 + C_2 + C_3 + \cdots + C_N$

B. $C_T = 1 + 2 = 3\ \mu F$

C. $C_T = 1 + 2 + 3 = 6\ \mu F$

In other words, the total capacitance is found by simple addition of the capacitor values.

42 Capacitors can be placed in series, as shown in Figure 1-19.

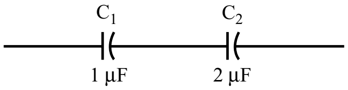

Figure 1-19

Questions

A. What is the formula for the total capacitance?

B. In Figure 1-19, what is the total capacitance?

Answers

A. $\frac{1}{C_T} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3} + \cdots + \frac{1}{C_N}$

B. $\frac{1}{C_T} = \frac{1}{1} + \frac{1}{2} = 1\frac{1}{2} = \frac{3}{2}$; thus $C_T = \frac{2}{3}$

43 In each of these examples the capacitors are placed in series. Find the total capacitance.

Questions

A. $C_1 = 10$ μF $C_2 = 5$ μF

B. $C_1 = 220$ μF $C_2 = 330$ μF $C_3 = 470$ μF

C. $C_1 = 0.33$ μF $C_2 = 0.47$ μF $C_3 = 0.68$ μF

Answers

A. 3.3 μF

B. 103.06 μF

C. 0.15 μF

Summary

The few simple principles reviewed in this chapter are those you need to begin the study of electronics. Following is a summary of these principles:

- The basic electrical circuit consists of a source (voltage), a load (resistance), and a path (conductor or wire).
- The voltage represents a charge difference.
- If the circuit is a complete circuit, then electrons will flow in what is called current flow. The resistance offers opposition to current flow.
- The relationship between V, I, and R is given by Ohm's law:

  $$V = I \times R$$

- Resistance could be a combination of resistors in series, in which case you add the values of the individual resistors together to get the total resistance.

  $$R_T = R_1 + R_2 + \cdots + R_N$$

- Resistance could be a combination of resistors in parallel, in which case you find the total by using the following formula:

  $$\frac{1}{R_T} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3} + \cdots + \frac{1}{R_N} \quad \text{or} \quad R_T = \frac{1}{\frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3} + \cdots + \frac{1}{R_N}}$$

- The power delivered by a source is found by using the following formula:

  $$P = VI$$

- The power dissipated by a resistance is found by using the following formula:

  $$P = I^2R \quad \text{or} \quad P = \frac{V^2}{R}$$

- If you know the total applied voltage, V_S, the voltage across one resistor in a series string of resistors is found by using the following voltage divider formula:

  $$V_1 = \frac{V_S R_1}{R_T}$$

- The current through one resistor in a two resistor parallel circuit with the total current known is found by using the current divider formula:

  $$I_1 = \frac{I_T R_2}{(R_1 + R_2)}$$

- Kirchhoff's voltage law (KVL) relates the voltage drops in a series circuit to the total applied voltage.

  $V_S = V_1 + V_2 + \cdots + V_N$

- Kirchhoff's current law (KCL) relates the currents at a junction in a circuit by saying that the sum of the input currents equals the sum of the output currents. For a simple parallel circuit, this becomes the following where I_T is the input current:

  $I_T = I_1 + I_2 + \cdots + I_N$

- A switch in a circuit is the control device that directs the flow of current or, in many cases, allows that current to flow.
- Capacitors are used to store electric charge in a circuit. They also allow current or voltage to change at a controlled pace. The circuit time constant is found by using the following formula:

  $\tau = R \times C$

- At one time constant in an RC circuit, the values for current and voltage have reached 63 percent of their final values. At five time constants, they have reached their final values.
- Capacitors in parallel are added to find the total capacitance.

  $C_T = C_1 + C_2 + \cdots + C_N$

- Capacitors in series are treated the same as resistors in parallel to find a total capacitance.

$$\frac{1}{C_T} = \frac{1}{C_1} + \frac{1}{C_2} + \cdots + \frac{1}{C_N} \quad \text{or} \quad C_T = \frac{1}{\frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3} + \cdots + \frac{1}{C_N}}$$

DC Pre-Test

The following problems and questions will test your understanding of the basic principles presented in this chapter. You will need a separate sheet of paper for your calculations. Compare your answers with the answers provided following the test. You will find that many of the problems can be worked more than one way.

Questions 1-5 use the circuit shown in Figure 1-20. Find the unknown values indicated using the values given.

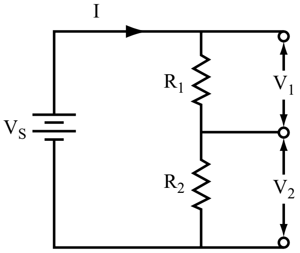

Figure 1-20

1. $R_1 = 12$ ohms, $R_2 = 36$ ohms, $V_S = 24$ V

   $R_T =$ ______________ , $I =$ ______________

2. $R_1 = 1$ KΩ, $R_2 = 3$ KΩ, $I = 5$ mA

   $V_1 =$ ______________ , $V_2 =$ ______________ , $V_S =$ ______________

3. $R_1 = 12$ kΩ, $R_2 = 8$ kΩ, $V_S = 24$ V

   $V_1 =$ ______________ , $V_2 =$ ______________

4. $V_S = 36$ V, $I = 250$ mA, $V_1 = 6$ V

   $R_2 =$ ______________

5. Now, go back to problem 1. Find the power dissipated by each resistor and the total power delivered by the source.

   $P_1 =$ ______________ , $P_2 =$ ______________ , $P_T =$ ______________

Questions 6-8 will use the circuit shown in Figure 1-21. Again, find the unknowns using the given values.

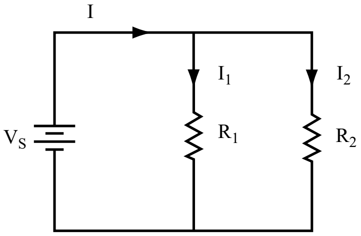

Figure 1-21

6. $R_1 = 6$ kΩ, $R_2 = 12$ kΩ, $V_S = 20$ V

   $R_T =$ ______________ , $I =$ ______________

7. $I = 2$ A, $R_1 = 10$ ohms, $R_2 = 30$ ohms

   $I_1 =$ ______________ , $I_2 =$ ______________

8. $V_S = 12$ V, I = 300 mA, $R_1 = 50$ ohms

$R_2 =$ ____________ , $P_1 =$ ____________

9. What is the maximum current that a 220 ohm resistor can safely have if its power rating is 1/4 watts?

$I_{MAX} =$ ____________

10. In a series RC circuit the resistance is 1 kΩ, the applied voltage is 3 V, and the time constant should be 60 μsec.

A. What is the required value of C?

C = ____________

B. What will be the voltage across the capacitor 60 μsec after the switch is closed?

$V_C =$ ____________

C. At what time will the capacitor be fully charged?

T = ____________

11. In the circuit shown in Figure 1-22, when the switch is at position 1, the time constant should be 4.8 ms.

A. What should be the value of resistor R_1?

$R_1 =$ ____________

B. What will be the voltage on the capacitor when it is fully charged, and how long will it take to reach this voltage?

$V_C =$ ____________ , T = ____________

C. After the capacitor is fully charged, the switch is thrown to position 2. What is the discharge time constant and how long will it take to completely discharge the capacitor?

$\tau =$ ____________ , T = ____________

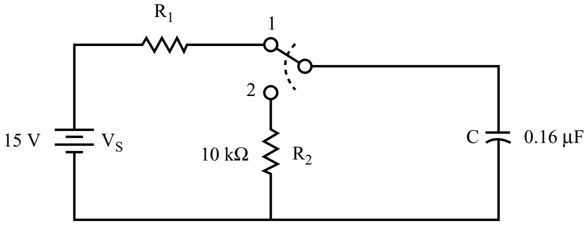

Figure 1-22

12. Three capacitors are available with the following values:

$C_1 = 8\ \mu F$; $C_2 = 4\ \mu F$; $C_3 = 12\ \mu F$.

A. What is C_T if all three are connected in parallel?

$C_T =$ ____________

B. What is C_T if they are connected in series?

$C_T =$ ____________

C. What is C_T if C_1 is in series with the parallel combination of C_2 and C_3?

$C_T =$ ____________

Answers to DC Pre-Test

If your answers do not agree with those provided here, review the problems indicated in parentheses before you go on to the next chapter. If you still feel uncertain about these concepts, go to a Web site such as `www.BuildingGadgets.com` and work through DC tutorials listed there.

It is assumed that Ohm's law is well known, so problem 4 will not be referenced.

1.		$R_T = 48$ ohms, $I = 0.5$ A	(problem 9)
2.		$V_1 = 5$ V, $V_2 = 15$ V, $V_S = 20$ V	(problems 23 and 26)
3.		$V_1 = 14.4$ V, $V_2 = 9.6$ V	(problem 23 and 263)
4.		$R_2 = 120$ ohms	(problems 9 and 23)
5.		$P_1 = 3$ W, $P_2 = 9$ W, $P_T = 12$ W	(problems 9 and 13)
6.		$R_T = 4$ kΩ, $I = 5$ mA	(problem 10)
7.		$I_1 = 1.5$ A, $I_2 = 0.5$ A	(problem 289)
8.		$R_2 = 200$ ohms, $P_1 = 2.88$ W	(problem 10 and 13)
9.		$I_{MAX} = 33.7$ mA	(problems 13, 15 and 16)
10.	A.	$C = 0.06\ \mu F$	(problems 34 and 35)
	B.	$V_C = 1.9$ V	
	C.	$T = 300\ \mu sec$	(34–38)

11.	A.	$R_1 = 30\ k\Omega$	(problems 35, 39 and 40)
	B.	$V_C = 15$ V, T = 24 ms	
	C.	$\tau = 1.6$ ms, T = 8.0 ms	(39–40)
12.	A.	24 μF	(problems 41 and 42)
	B.	2.18 μF	
	C.	5.33 μF	(42–43)

CHAPTER 2

The Diode

The main characteristic of a diode is that it conducts electricity in one direction only. Historically, the first vacuum tube was a diode; it was also known as a *rectifier.* The modern diode is a semiconductor device. It is used in all applications where the older vacuum tube diode was used, but it has the advantages of being much smaller, easier to use, and less expensive.

A *semiconductor* is a crystalline material that, depending on the conditions, can act as a conductor (allowing the flow of electric current) or an insulator (preventing the flow of electric current). Techniques have been developed to customize the electrical properties of adjacent regions of semiconductor crystals, which allow the manufacture of very small diodes, as well as transistors and integrated circuits.

When you complete this chapter you will be able to do the following:

- Specify the uses of diodes in DC circuits
- Determine from a circuit diagram whether a diode is forward or reverse biased
- Recognize the characteristic V-I curve for a diode
- Specify the knee voltage for a silicon or a germanium diode
- Calculate current and power dissipation in a diode
- Define diode breakdown
- Differentiate between zeners and other diodes
- Determine when a diode can be considered ‘‘perfect’’

Understanding Diodes

1 Silicon and germanium are semiconductor materials used in the manufacture of diodes, transistors, and integrated circuits. Semiconductor material is refined to an extreme level of purity, and then minute, controlled amounts of a specific impurity are added (a process called *doping*). Based on which impurity is added to a region of a semiconductor crystal, that region is said to be *N type* or *P type.* In addition to electrons (which are negative charge carriers used to conduct charge in a conventional conductor), semiconductors contain positive charge carriers called *holes.* The impurities added to an N type region increases the number of electrons capable of conducting charge, while the impurities added to a P type region increase the number of holes that are capable of conducting charge.

When a semiconductor chip contains an N doped region adjacent to a P doped region, a *diode junction* (often called a *PN junction*) is formed. Diode junctions can also be made with either silicon or germanium. However, silicon and germanium are never mixed when making PN junctions.

Question

Which diagrams in Figure 2-1 show diode junctions?

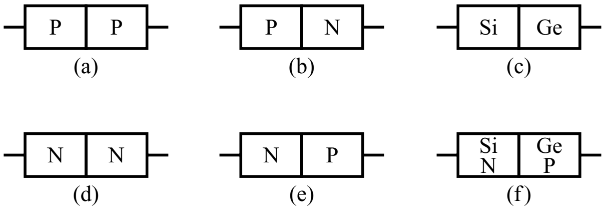

Figure 2-1

Answer

Diagrams (b) and (e) only

2 In a diode, the P material is called the *anode.* The N material is called the *cathode.*

Question

Identify which part of the diode shown in Figure 2-2 is P material and which part is N material.

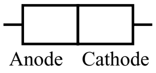

Figure 2-2

Answer

The anode is P material, the cathode is N material.

3 Diodes are useful because electric current will flow through a PN junction *in one direction only*. Figure 2-3 shows the direction in which the current flows.

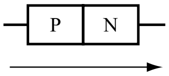

Figure 2-3

The circuit symbol for a diode is shown in Figure 2-4. The arrowhead points in the direction of current flow. While the anode and cathode are indicated here, they are not usually indicated in circuit diagrams.

Figure 2-4

Question

In a diode, does current flow from anode to cathode, or cathode to anode?

Answer

Current flows from anode to cathode.

4 In the circuit shown in Figure 2-5, an arrow shows the direction of current flow.

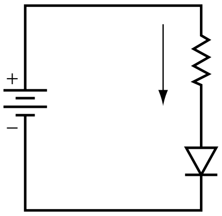

Figure 2-5

Questions

A. Is the diode connected correctly to permit current to flow?

____

B. Notice the way the battery and the diode are connected. Is the anode at a higher or lower voltage than the cathode?

____

Answers

A. Yes.

B. The anode is connected to the positive battery terminal, and the cathode is connected to the negative battery terminal. Therefore, the anode is at a higher voltage than the cathode.

5 When the diode is connected so that the current is flowing, it is said to be *forward biased*. In a forward biased diode, the anode is connected to a higher voltage than the cathode, and current is flowing. Examine the way the diode is connected to the battery in Figure 2-6.

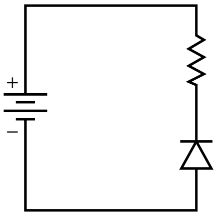

Figure 2-6

Question

Is the diode forward biased or not? Give the reasons for your answer.

____

Answer

No, it is not forward biased. The cathode is connected to the positive battery terminal and the anode is connected to the negative battery terminal. Therefore, the cathode is at a higher voltage than the anode.

6 When the cathode is connected to a higher voltage level than the anode, the diode cannot conduct. In this case, the diode is said to be *reverse biased*.

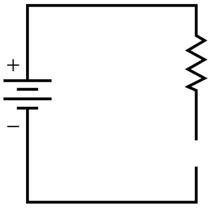

Figure 2-7

Question

Draw a reverse biased diode in the circuit shown in Figure 2-7.

Answer

Your drawing should look something like Figure 2-8.

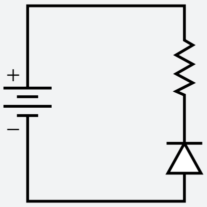

Figure 2-8

7 In many circuits, the diode is often considered to be a *perfect* diode to simplify calculations. A perfect diode has zero voltage drop in the forward direction, and conducts no current in the reverse direction.

Question

From your knowledge of basic electricity, what other component has zero voltage drop across its terminals in one condition, and conducts no current in an alternative condition?

Answer

The mechanical switch. When closed, it has no voltage drop across its terminals, and when open, it conducts no current.

8 A forward biased perfect diode can thus be compared to a closed switch. It has no voltage drop across its terminals and current flows through it.

A reverse biased perfect diode can be compared to an open switch. No current flows through it and the voltage difference between its terminals equals the supply voltage.

Question

Which of the switches shown in Figure 2-9 performs like a forward biased perfect diode?

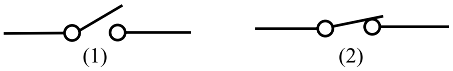

Figure 2-9

Answer

Switch (2) represents a closed switch and, like a forward biased perfect diode, allows current to flow through it. There is no voltage drop across its terminals.

The Diode Experiment

9 If you have access to electronic equipment, you may wish to perform the simple experiment described in the next few problems. If this is the first time you have tried such an experiment, get help from an instructor or someone who is familiar with electronic experiments.

If you do not have access to equipment, do not skip this exercise. Read through the experiment and try to picture or imagine the results. This is sometimes called ''dry-labbing'' the experiment. You can learn a lot from this exercise, even though it is always better to actually perform the experiment. This advice also applies to the other experiments that are given in many of the following chapters.

The objective of this experiment is to plot the V-I curve (also called a *characteristic curve*) of a diode, which shows how current flow through the diode varies with the applied voltage. As shown in Figure 2-10, the I-V curve for a diode demonstrates that if very little voltage is applied to a diode, current will not flow. However, once the applied voltage exceeds a certain value, the current flow increases quickly.

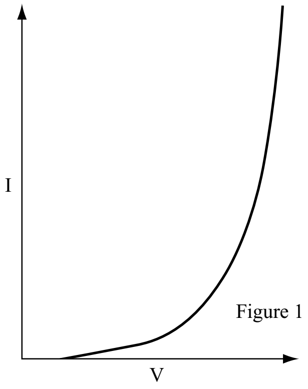

Figure 2-10

In performing this experiment, you will gain experience in the following:

- Setting up a simple electronic experiment
- Measuring voltage and current
- Plotting a graph of these

Set up the circuit shown on Figure 2-11. The circled A and V designate meters. The ammeter will measure current, and the voltmeter will measure voltage in the circuit.

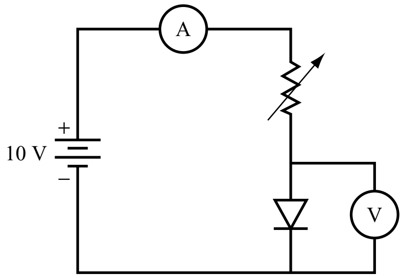

Figure 2-11

You can use two multimeters set to either measure current or voltage. Because you need to change the resistance at each step in the experiment, try using a 1 megohm potentiometer and measure its resistance value after each adjustment. If you don't have a 1 megohm potentiometer, but do have a collection of resistors with values ranging from a few hundred ohms to 1 megohm, you can simply change resistors at each step. Carefully check your circuit against the diagram, especially the direction of the battery and the diode.

Once you have checked your circuit, follow these steps:

1. Set R to its highest value and record it in the following table.

R	V	I
ohms	**volts**	**mA**

2. Close the switch and measure I and V. Record them in the table.
3. Lower the value of R a little to get a different reading of I.
4. Measure and record I and V again.
5. Continue in this fashion, taking as many readings as possible. There will suddenly come a point when V will not increase, but I will increase very rapidly. STOP.

NOTE **If V gets very large — above 3 or 4 volts — and I remains very small, then the diode is backward. Reverse it and start again.**

6. Graph the points recorded in the table, using the blank graph in Figure 2-12. Your curve should look like the one in Figure 2-10.

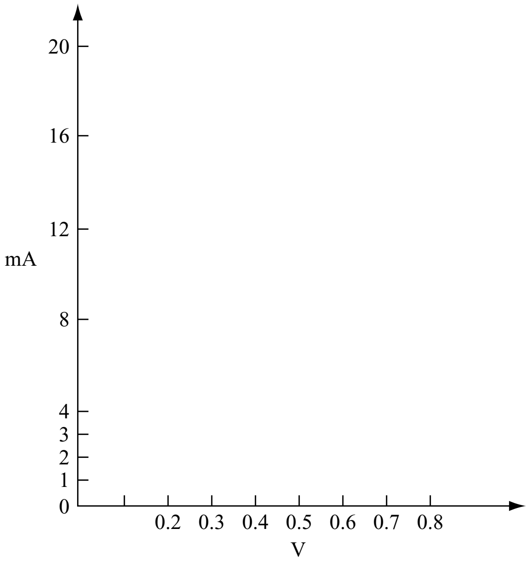

Figure 2-12

10 The measurements in the following table were taken using a commercial 1N4001 diode.

R	V	I
ohms	**volts**	**mA**
1 MΩ	0.30	0.02
220 kΩ	0.40	0.05
68 kΩ	0.46	0.14
33 kΩ	0.50	0.26
15 kΩ	0.52	0.50
10 kΩ	0.55	0.80
6.8 kΩ	0.56	1.20
4.7 kΩ	0.60	2.00
3.3 kΩ	0.62	2.80
2.2 kΩ	0.64	4.20
1.5 kΩ	0.65	5.50

R	V	I
ohms	**volts**	**mA**
1.0 kΩ	0.67	8.40
680 Ω	0.70	12.00
470 Ω	0.70	18.00
330 Ω	0.71	23.00

Further reductions in the value of R will cause very little increase in the voltage, but will produce large increases in the current.

Figure 2-13 is the V-I curve generated using the measurements shown in the preceding table.

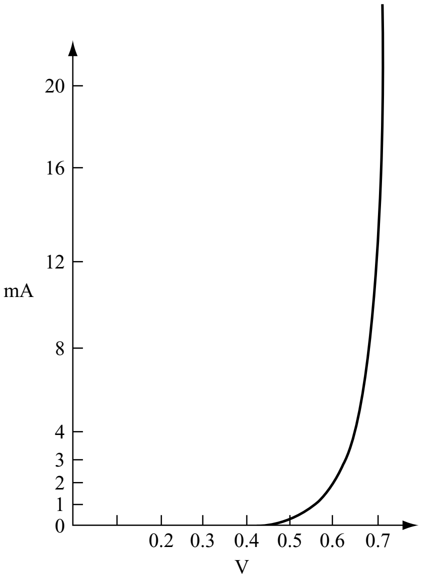

Figure 2-13

The V-I curve (or diode characteristic curve) is repeated in Figure 2-14 with three important regions marked on it.

The most important region is the *knee region*. This is not a sharply defined changeover point, but it occupies a very narrow range of the curve, where the diode resistance changes from high to low.

The ideal curve is shown for comparison.

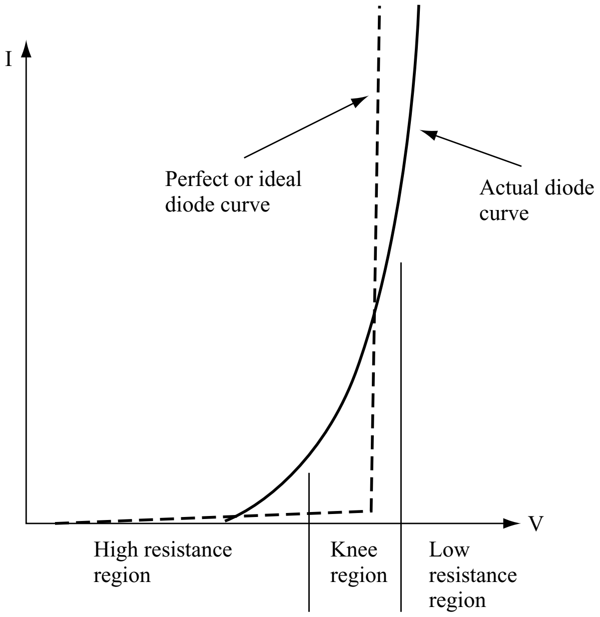

Figure 2-14

For the diode used in this problem, the knee voltage is about 0.7 V, which is typical for a silicon diode. This means (and your data should verify this) that at voltage levels below 0.7 V, the diode has such a high resistance that it limits the current flow to a very low value. This characteristic knee voltage is sometimes referred to as a *threshold voltage*. If you use a germanium diode, the knee voltage is about 0.3 V.

Question

What is the knee voltage for the diode you used?

____

Answer

If you use silicon, the knee voltage would be approximately 0.7 V; with germanium, it would be approximately 0.3 V.

11 The knee voltage is also a *limiting voltage*. That is, it is the highest voltage that can be obtained across the diode in the forward direction.

Questions

A. Which has the higher limiting voltage, germanium or silicon?

____

B. What happens to the diode resistance at the limiting or knee voltage?

____

Answers

A. Silicon, with a limiting voltage of 0.7 V, is higher than germanium, which has a limiting voltage of only 0.3 V.

B. It changes from high to low.

NOTE **You will be using these knee voltages in many later chapters as the voltage drop across the PN junction when it is forward biased.**

12 Refer back to the diagram of resistance regions in Figure 2-14.

Question

What happens to the current when the voltage becomes limited at the knee?

____

Answer

It increases rapidly.

13 For any given diode, the knee voltage will not be exactly 0.7 V or 0.3 V. Rather, it will vary slightly. But when using diodes in practice (that is, imperfect diodes), you can make two assumptions:

- The voltage drop across the diode is either 0.7 V or 0.3 V.
- Excessive current is prevented from flowing through the diode by using the appropriate resistor in series with the diode.

Questions

A. Why are imperfect diodes specified here?

____

B. Would you use a high or low resistance to prevent excessive current?

____

Answers

A. All diodes are imperfect, and the 0.3 or 0.7 voltage values are only approximate. In fact, in some later problems, it is assumed that the voltage drop across the diode, when it is conducting, is 0 V. This assumes, then, that as soon as you apply any voltage above 0, current flows in an ideal resistor (that is, the knee voltage on the V-I curve for an ideal diode is 0 volts).

B. Generally use a high resistance. However, the actual resistance value can be calculated given the applied voltage and the maximum current the diode can withstand.

14 Calculate the current through the diode in the circuit shown in Figure 2-15, using the steps in the following question.

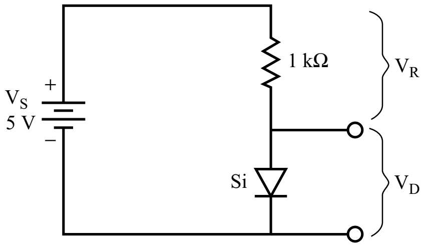

Figure 2-15

Questions

A. The voltage drop across the diode is known. It is 0.7 V for silicon and 0.3 V for germanium. (''Si'' near the diode means it is silicon.) Write down the diode voltage drop.

V_D = ____________________

B. Find the voltage drop across the resistor. This can be calculated using $V_R = V_s - V_D$. This is taken from KVL, which was discussed in Chapter 1.

$V_R =$ ______

C. Calculate the current through the resistor. Use $I = V_R/R$.

$I =$ ______

D. Finally, determine the current through the diode.

$I =$ ______

Answers

You should have written these values.

A. 0.7 V

B. $V_R = V_s - V_D = 5\text{ V} - 0.7\text{ V} = 4.3\text{ V}$

C. $I = \dfrac{V_R}{R} = \dfrac{4.3\,\text{V}}{1\,\text{k}\Omega} = 4.3\,\text{mA}$

D. 4.3 mA (In a series circuit the same current runs through each component.)

15 In practice, when the battery voltage is 10 V or above, the voltage drop across the diode is often considered to be 0 V instead of 0.7 V.

The assumption here is that the diode is a perfect diode, and the knee voltage is at 0 V rather than at a threshold value that must be exceeded. As discussed later, this assumption is often used in many electronic designs.

Questions

A. Calculate the current through the silicon diode shown in Figure 2-16.

$V_D =$ ______

$V = V_s - V_D =$ ______

$I = \dfrac{V_R}{R} =$ ______

$I_D =$ ______

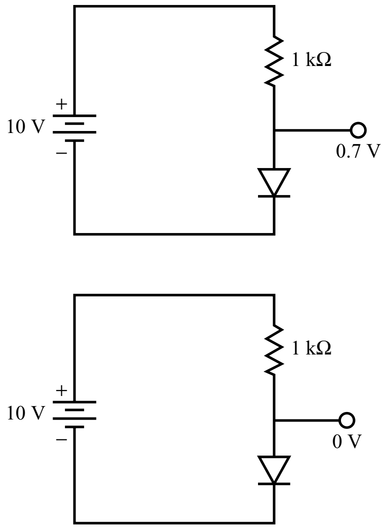

Figure 2-16

B. Calculate the current through the perfect diode shown in Figure 2-16.

$V_D =$ ______________________________

$V_R = V_s - V_D =$ ____________________

$I = \frac{V_R}{R} =$ ___________________________

$I_D =$ _______________________________

Answers

A. 0.7 V; 9.3 V; 9.3 mA; 9.3 mA

B. 0 V; 10 V; 10 mA; 10 mA

16 The difference in the values of the two currents found in problem 15 is less than 10 percent of the total current. That is, 0.7 mA is less than 10 percent of 10 mA. Many electronic components have a plus or minus 5 percent tolerance in their nominal values. This means that a 1 k resistor can be anywhere from 950 ohms to 1,050 ohms, meaning that the value of current through a resistor can vary plus or minus 5 percent.

Because of slight variance in component values, calculations are often simplified if the simplification does not change values by more than 10 percent. Therefore, a diode is often assumed to be perfect when the supply voltage is 10 V or more.

Questions

A. Examine the circuit in Figure 2-17. Is it safe to assume that the diode is perfect?

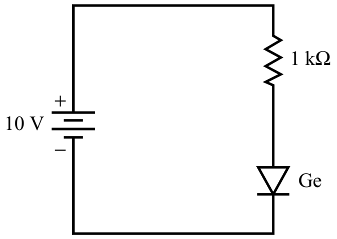

Figure 2-17

B. Calculate the current through the diode.

Answers

A. Yes, it can be considered a perfect diode.

B. I = 10 mA

17 When a current flows through a diode, it causes heating and power dissipation, just as with a resistor. The power formula for resistors is $P = V \times I$. This same formula can be applied to diodes to find the power dissipation. To calculate the power dissipation in a diode, you must first calculate the current as shown previously. The voltage drop in this formula is assumed to be 0.7 V for a silicon diode, even if you considered it to be 0 V when calculating the current.

For example, a silicon diode has 100 mA flowing through it. Determine how much power the diode dissipates.

$$P = (0.7\,\text{V})(100\,\text{mA}) = 70\,\text{mW}$$

Question

Assume a current of 2 amperes is flowing through a silicon diode. How much power is being dissipated?

Answer

$P = (0.7\,V)\,(2\,A) = 1.4\,\text{watts}$

18 Diodes are made to dissipate a certain amount of power, and this is quoted as a maximum power rating in the manufacturer's specifications of the diode.

Assume a silicon diode has a maximum power rating of 2 watts. How much current can it safely pass?

$$P = V \times I$$
$$I = \frac{P}{V}$$
$$= \frac{2\,\text{watts}}{0.7\,V}$$

2.86 A (rounded off to two decimal places)

Provided the current in the circuit does not exceed this, the diode will not overheat and burn out.

Question

Suppose the maximum power rating of a germanium diode is 3 watts. What is its highest safe current?

Answer

$$I = \frac{3\,\text{watts}}{0.3\,V} = 10\,A$$

19 Answer the following questions for another example.

Questions

A. Would a 3 watt silicon diode be able to carry the current calculated for the germanium diode for problem 18?

B. What would be its safe current?

Answers

A. No, 10 amperes would cause a power dissipation of 7 watts, which would burn up the diode.

B. $I = \frac{3}{0.7} = 4.3\,A$

Any current less than this would be safe.

20 The next several examples concentrate on finding the current through the diode. Look at the circuit shown in Figure 2-18.

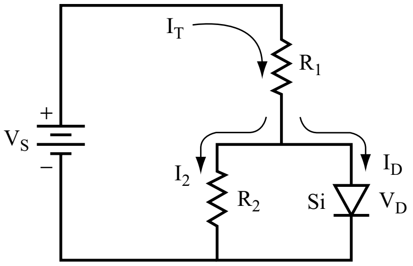

Figure 2-18

The total current from the battery flows through R_1, and then splits into I_2 and I_D. I_2 flows through R_2 and I_D through the diode.

Questions

A. What is the relationship between I_T, I_2, and I_D?

B. What is the value of V_D?

____

Answers

A. Remember KCL, $I_T = I_2 + I_D$

B. $V_D = 0.7$ V

21 To find I_D, it is necessary to go through the following steps because there is no way of finding I_D directly.

1. Find I_2. This is done using $V_D = R_2 \times I_2$.
2. Find V_R. For this use $V_R = V_s - V_D$ (KVL again).
3. Find I_T, the current through R_1. Use $V_R = I_T \times R_1$.
4. Find I_D. This is found by using $I_T = I_2 + I_D$ (KCL again).

To find I_D in the circuit shown in Figure 2-19, go through these steps, and then check your answers.

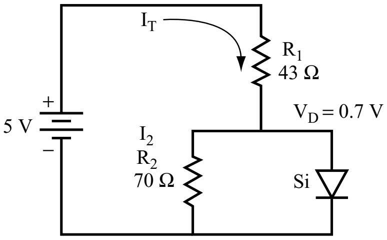

Figure 2-19

Questions

A. $I_2 =$

____

B. $V_R =$

____

C. $I_T =$

____

D. I_D =

____

Answers

A. $I_2 = \dfrac{V_D}{R_2} = \dfrac{0.7\,V}{R_2} = \dfrac{0.7\,V}{70\,\text{ohms}} = 0.01\,A = 10\,mA$

B. $V_R = V_S - V_D = 5\ V - 0.7\ V = 4.3\ V$

C. $I_T = \dfrac{V_R}{R_1} = \dfrac{4.3\,V}{43\,\text{ohms}} = 0.1\,A = 100\,mA$

D. $I_D = I_T - I_2 = 100\ mA - 10\ mA = 90\ mA$

22 For this problem, refer to your answers in problem 21.

Question

What is the power dissipation of the diode in problem 21?

____

Answer

$P = V_D \times I_D = (0.7\ V)(90\ mA) = 63$ milliwatts

23 To find the current in the diode for the circuit shown in Figure 2-20, answer these questions in order:

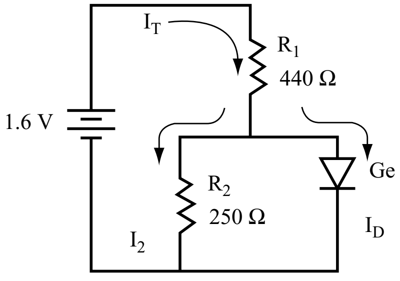

Figure 2-20

Questions

A. $I_2 =$ ____________________________

B. $V_R =$ ____________________________

C. $I_T =$ ____________________________

D. $I_D =$ ____________________________

Answers

A. $I_2 = \frac{0.3}{250} = 1.2\,\text{mA}$

B. $V_R = V_S - V_D = 1.6 - 0.3 = 1.3\ \text{V}$

C. $I_T = \frac{V_R}{R_1} = \frac{1.3}{440} = 3\,\text{mA}$

D. $I_D = I_T - I_2 = 1.8\ \text{mA}$

If you are going to take a break soon, this is a good stopping point.

Diode Breakdown

24 Earlier, you read that if the experiment is not working correctly, then the diode is probably in backward. If you place the diode in the circuit backward — as shown on the right in Figure 2-21 — then almost no current flows. In fact, the current flow is so small, it can be said that no current flows. The V-I curve for a reversed diode looks like the one shown on the left in Figure 2-21.

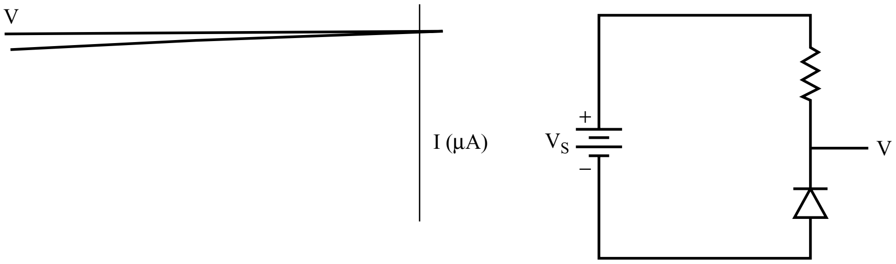

Figure 2-21

The V-I curve for a perfect diode would show zero current for all voltage values. But for a real diode, a voltage is reached where the diode ''breaks down'' and the diode allows a large current to flow. The V-I curve for the diode breakdown would then look like the one in Figure 2-22.

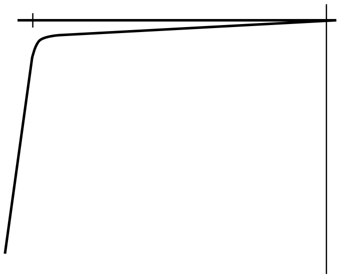

Figure 2-22

If this condition continues, the diode will burn out. You can avoid burning out the diode, even though it is at the breakdown voltage, by limiting the current with a resistor.

Question

The diode in the circuit shown in Figure 2-23 is known to break down at 100 V, and it can safely pass 1 ampere without overheating. Find the resistance in this circuit that would limit the current to 1 ampere.

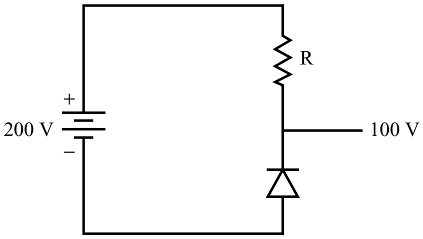

Figure 2-23

Answer

$V_R = V_s - V_D = 200\,\text{V} - 100\,\text{V} = 100\,\text{V}$

Since 1 ampere of current is flowing, then:

$$R = \frac{V_R}{I} = \frac{100\,\text{V}}{1\,\text{A}} = 100\,\text{ohms}$$

25 All diodes will break down when connected in the reverse direction if excess voltage is applied to them. The breakdown voltage, which is a function of how the diode is made, varies from one type of diode to another. This voltage is quoted in the manufacturer's datasheet.

Breakdown is not a catastrophic process and does not destroy the diode. If the excessive supply voltage is removed, the diode will recover and operate normally. You can use it safely many more times, provided the current is limited to prevent the diode from burning out.

A diode will always break down at the same voltage, no matter how many times it is used.

The breakdown voltage is often called the *peak inverse voltage* (PIV) or the *peak reverse voltage* (PRV). Following are the PIVs of some common diodes:

DIODE	PIV
1N4001	50 V
1N4002	100 V
1N4003	200 V
1N4004	400 V
1N4005	600 V
1N4006	800 V

Questions

A. Which can permanently destroy a diode, excessive current or excessive voltage?

____

B. Which is more harmful to a diode, breakdown or burnout?

____

Answers

A. Excessive current. Excessive voltage will not harm the diode if the current is limited.

B. Burnout. Breakdown is not necessarily harmful, especially if the current is limited.

The Zener Diode

26 Diodes can be manufactured so that breakdown occurs at lower and more precise voltages than those just discussed. These types of diodes are called *zener diodes*, so named because they exhibit the ‘‘Zener effect’’ — a particular form of voltage breakdown. At the zener voltage, a small current will flow through the zener diode. This current must be maintained to keep the diode at the zener point. In most cases, a few milliamperes are all that is required. The zener diode symbol and a simple circuit are shown in Figure 2-24.

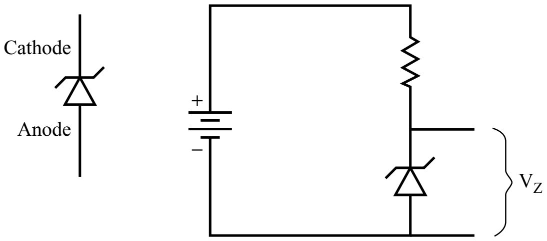

Figure 2-24

In this circuit, the battery determines the applied voltage. The zener diode determines the voltage drop (labeled V_z) across it. The resistor determines the current flow. Zeners are used to maintain a constant voltage at some point in a circuit.

Question

Why are zeners used for this purpose, rather than ordinary diodes?

____

Answer

Because zeners have a precise breakdown voltage

27 Examine an application in which a constant voltage is desirable — for example, a lamp driven by a DC generator. In this example, when the generator is turning at full speed, it puts out 50 V. When it is running more slowly, the voltage can drop to 35 V. You want to illuminate a 20 V lamp with this generator. Assume the lamp draws 1.5 A. The circuit is shown in Figure 2-25.

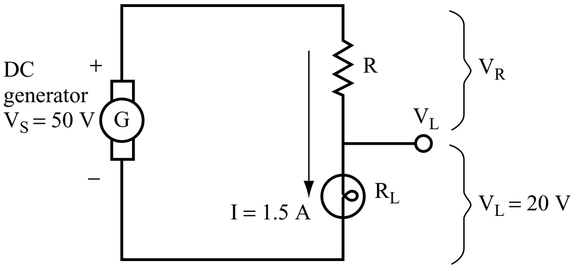

Figure 2-25

You need to determine a suitable value for the resistance. Follow these steps to find a suitable resistance value:

1. Find R_L, the lamp resistance. Use
$$R_L = \frac{V_L}{I}$$
2. Find V_R. Use $V_S = V_R + V_L$.
3. Find R. Use
$$R = \frac{V_R}{I}$$

Questions

Work through these steps, and write your answers here.

A. $R_L =$ ____

B. $V_R =$ ____

C. $R =$ ____

Answers

A. $R_L = \frac{20\text{ V}}{1.5\text{ A}} = 13.33$ ohms

B. $V_R = 50\text{ V} - 20\text{ V} = 30\text{ V}$

C. $R = \frac{50\,V - 20\,V}{1.5\,A} = \frac{30\,V}{1.5\,A} = 20\,\text{ohms}$

28 Assume now that the 20 ohm resistor calculated in problem 27 is in place, and the voltage output of the generator drops to 35 V, as shown in Figure 2-26. This is similar to what happens when a battery gets old. Its voltage level decays and it will no longer have sufficient voltage to produce the proper current. This results in the lamp glowing less brightly, or perhaps not at all. Note, however, that the resistance of the lamp stays the same.

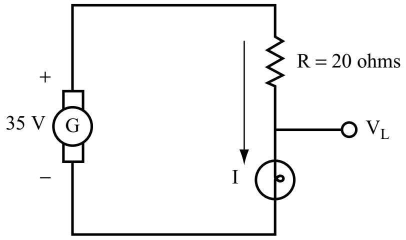

Figure 2-26

Questions

A. Find the total current flowing. Use

$$I_T = \frac{V_S}{(R + R_L)}$$

I_T =

B. Find the voltage drop across the lamp. Use $V_L = I_T \times R_L$

V_L =

C. Have the voltage and current increased or decreased?

Answers

A. $I_T = \frac{35\,V}{20\,\Omega + 13.3\,\Omega} = \frac{35\,V}{33.3\,\Omega} = 1.05\,A$

B. $V_L = 1.05\ A \times 13.3\ \Omega = 14\ V$

C. Both have reduced in value.

29 In many applications, a lowering of voltage across the lamp (or some other component) may be unacceptable. This can be prevented by using a zener diode, as shown in the circuit in Figure 2-27.

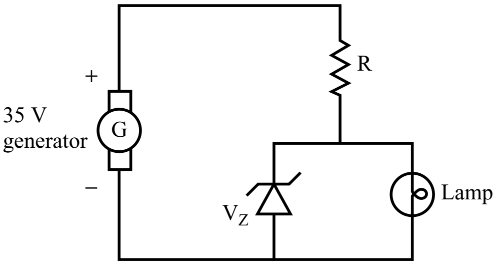

Figure 2-27

If you choose a 20 V zener (that is, one that has a 20 V drop across it), then the lamp will always have 20 V across it, no matter what the output voltage is from the generator (provided, of course, that the output from the generator is always above 20 V).

Questions

Say that the voltage across the lamp is constant, and the generator output drops.

A. What happens to the current through the lamp?

____

B. What happens to the current through the zener?

____

Answers

A. The current stays constant because the voltage across the lamp stays constant.

B. The current decreases because the total current decreases.

30 To make this circuit work and keep 20 V across the lamp at all times, you must find a suitable value of R. This value should allow sufficient total current to flow to provide 1.5 amperes required by the lamp, and the small amount required to keep the diode at its zener voltage. To do this, you start at the ''worst case'' condition. (''Worst case'' design is a common practice in electronics. It is used to ensure that equipment will work under the most adverse conditions.) The worst case here would occur when the generator is putting out only 35 V. Figure 2-28 shows the paths that current would take in this circuit.

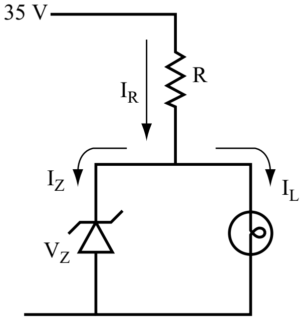

Figure 2-28

Find the value of R which will allows 1.5 A to flow through the lamp. How much current will flow through the zener diode? You can choose any current you like, provided it is above a few milliamperes, and provided it will not cause the zener diode to burn out. In this example assume that the zener current I_z is 0.5 A.

Questions

A. What is the total current through R?

I_R = ____________________

B. Calculate the value of R.

R = ____________________

Answers

A. $I_R = I_L + I_Z = 1.5\text{ A} + 0.5\text{ A} = 2\text{ A}$

B. $R = \dfrac{(V_S - V_Z)}{I_R} = \dfrac{(35\text{ volts} - 20\text{ volts})}{2\text{ A}} = 7.5\text{ ohms}$

A different choice of I_z here would produce another value of R.

31 Now take a look at what happens when the generator is supplying 50 V, as shown in Figure 2-29.

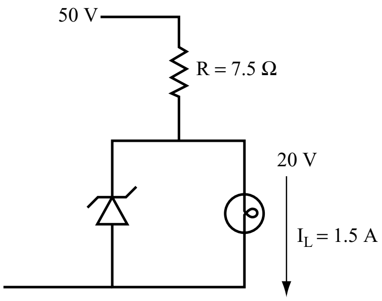

Figure 2-29

Because the lamp still has 20 V across it, it will still draw only 1.5 A. But the total current and the zener current will change.

Questions

A. Find the total current through R.

$I_R =$

B. Find the zener current.

$I_Z =$

Answers

A. $I_R = d\frac{(V_S - V_Z)}{R} = \frac{(50 - 20)}{7.5} = 4\text{ A}$

B. $I_Z = I_R - I_L = 4 - 1.5 = 2.5\text{ A}$

32 Although the lamp voltage and current remain the same, the total current and the zener current both changed.

Questions

A. What has happened to I_T (I_R)?

B. What has happened to I_Z?

Answers

A. I_T has increased by 2 A.

B. I_Z has increased by 2 A.

Note that the increase in I_T flows through the zener diode and not through the lamp.

---

33 The power dissipated by the zener diode changes as the generator voltage changes.

Questions

A. Find the power dissipated when the generator voltage is 35 V.

B. Now find the power when the generator is at 50 V.

Answers

A. $P_Z = V \times I = (20 \text{ volts})\ (0.5\text{ A}) = 10$ watts

B. $P_Z = V \times I = (20 \text{ volts})\ (2.5\text{ A}) = 50$ watts

If you use a zener diode with a power rating of 50 watts or more, it will not burn out.

34 Use Figure 2-30 to answer the following question.

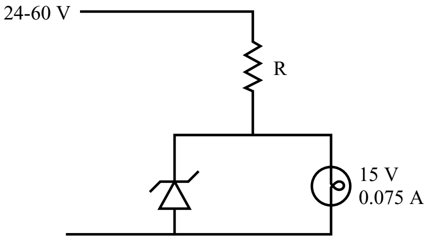

Figure 2-30

Question

For the circuit shown in Figure 2-30, what power rating should the zener diode have? The current and voltage ratings of the lamp are given.

Answer

At 24 volts, assuming a zener current of 0.5 A:

$$R = \frac{9}{0.575} = 15.7\,\text{ohms}$$

At 60 V:

$$I_R = \frac{45}{15.7} = 2.87\text{A; therefore } I_Z \approx 2.8\text{ A}$$

$$P_Z = (15\text{ volts})(2.8\text{ A}) = 42\text{ watts}$$

Summary

Semiconductor diodes are used extensively in modern electronic circuits. The main advantages of semiconductor diodes are:

- They are very small.
- They are rugged and reliable if properly used. You must remember that excessive reverse voltage or excessive forward current could damage or destroy the diode.
- Diodes are very easy to use, as there are only two connections to make.
- They are inexpensive.
- They can be used in all types of electronic circuits, from simple DC controls to radio and TV circuits.
- They can be made to handle a wide range of voltage and power requirements.
- Specialized diodes (which have not been covered here) can perform particular functions, which no other components can handle.
- Finally, as you will see in the next chapter, diodes are an integral part of transistors.

All of the many uses of semiconductor diodes are based on the fact they conduct in *one direction only*. Diodes are often used for the following:

- Protecting circuit components from voltage spikes
- Converting AC to DC

- Protecting sensitive components from high-voltage spikes
- Building high speed switches
- Rectifying radio frequency signals

Self-Test

The following questions test your understanding of this chapter. Use a separate sheet of paper for your diagrams or calculations. Compare your answers with the answers that follow the test.

1. Draw the circuit symbol for a diode, labeling each terminal.

2. What semiconductor materials are used in the manufacture of diodes?

3. Draw a circuit with a battery, resistor, and a forward biased diode.

4. What is the current through a reverse biased perfect diode?

5. Draw a typical V-I curve of a forward biased diode. Show the knee voltage.

6. What is the knee voltage for silicon?

   Germanium?

7. In the circuit shown in Figure 2-31, $V_S = 10$ V and $R = 100$ ohms. Find the current through the diode, assuming a perfect diode.

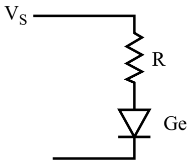

Figure 2-31

8. Calculate question 7 using these values: $V_S = 3$ V and R = 1 kΩ.

9. In the circuit shown in Figure 2-32, find the current through the diode.

$V_S = 10$ V
$R_1 = 10$ kΩ
$R_2 = 1$ kΩ

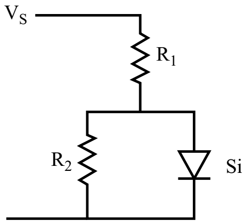

Figure 2-32

10. In the circuit shown in Figure 2-33, find the current through the zener diode.

$V_S = 20$ V
$V_Z = 10$ V
$R_1 = 1$ kΩ
$R_2 = 2$ kΩ

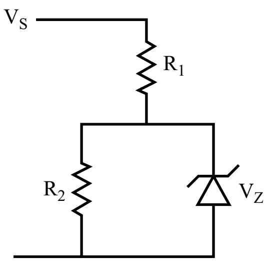

Figure 2-33

11. If the supply voltage for question 10 increases to 45 V, what is the current in the zener diode?

---

12. What is the maximum power dissipated for the diode in questions 10 and 11?

Answers to Self-Test

If your answers do not agree with those given below, review the problems indicated in parentheses before you go on to the next chapter.

1.	See Figure 2-34.	(problem 3)
	 **Figure 2.34**	
2.	Germanium and silicon	(problem 1)
3.	See Figure 2-35.	(problem 4)
	 **Figure 2.35**	
4.	There is zero current flowing through the diode.	(problem 6)

5.	See Figure 2-36.	(problem 9 and 10)

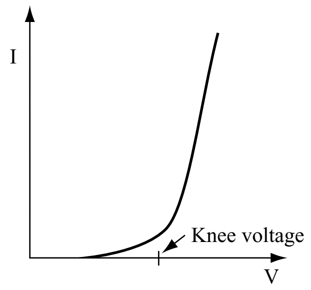

Figure 2.36

6.	Si = 0.7 V; Ge = 0.3 V (These are approximate.)	(problem 10)
7.	$I_D = 100$ mA	(problem 14)
8.	As $V_S = 3$ V, do not ignore the voltage drop across the diode. Thus, $I_D = 2.7$ mA	(problem 14)
9.	Ignore V_D in this case. Thus, $I_D = 0.3$ mA. If V_D is not ignored, $I_D = 0.23$ mA.	(problem 21)
10.	$I_Z = 5$ mA	(problem 31)
11.	$I_Z = 30$ mA	(problem 31)
12.	The maximum power will be dissipated when I_Z is at its peak value of 30 mA. Therefore, $P_Z(MAX) = 0.30$ W.	(problem 33)

CHAPTER 3

Introduction to the Transistor

The transistor is undoubtedly the most important modern electronic component because it has enabled great and profound changes in electronics and in our daily lives since its discovery in 1948.

This chapter introduces the transistor as an electronic component that acts similarly to a simple mechanical switch, and, in fact, it is actually used as a switch in many modern electronic devices. A transistor can be made to conduct or not conduct an electric current — exactly what a mechanical switch does.

Most transistors used in electronic circuits are *bipolar junction transistors* (BJT), commonly referred to as *bipolar transistors*, *junction field effect transistors* (JFET), or *metal oxide silicon field effect transistors* (MOSFET). This chapter (along with Chapters 4 and 8) illustrates how BJTs and JFETs function and how they are used in electronic circuits. Because JFETs and MOSFETs function in similar fashion, MOSFETs are not covered here.

An experiment in this chapter will help you to build a simple one-transistor switching circuit. You can easily set up this circuit on a home workbench. You should take the time to obtain the few components required and actually perform the experiment of building and operating the circuit.

In Chapter 4, you will continue to study switching designs and the operation of the transistor as a switch. In Chapter 8, you learn how a transistor can be made to operate as an amplifier. In this mode, the transistor produces an output that is a magnified version of an input signal, which is useful because many electronic signals require amplification. These chapters taken together present an easy introduction to how transistors function and how they are used in basic electronic circuits.

When you complete this chapter, you will be able to do the following:

- Describe the basic construction of a bipolar junction transistor (BJT).
- Describe the basic construction of a junction field effect transistor (JFET).
- Specify the relationship between base and collector current in a BJT.
- Specify the relationship between gate voltage and drain current in a JFET.
- Calculate the current gain for a BJT.
- Compare the transistor to a simple mechanical switch.

Understanding Transistors

1 The diagrams in Figure 3-1 show some common transistor cases (also called *packages*). The cases protect the semiconductor chip on which the transistor is built, and provide leads that can be used to connect it to other components. For each transistor, the diagrams show the lead designations and how to identify them based on the package design. Transistors can be soldered directly into a circuit, inserted into sockets, or inserted into breadboards. When soldering, you must take great care, because transistors can be destroyed if overheated. A heat sink clipped to the transistor leads between the solder joint and the transistor case can reduce the possibility of overheating. If you're using a socket, you can avoid exposing the transistor to heat by soldering the connections to the socket before inserting the transistor.

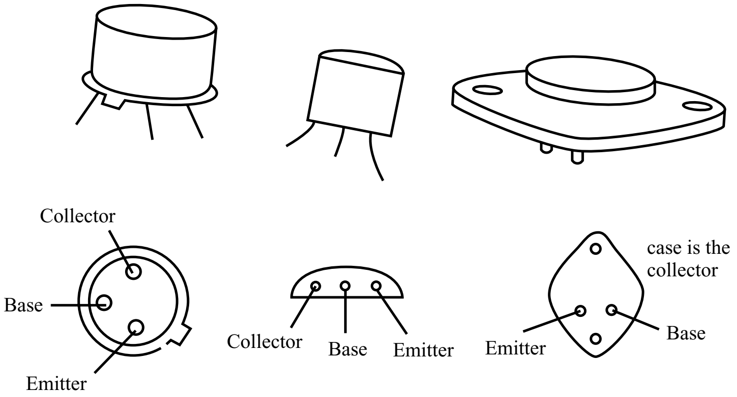

Figure 3-1

Questions

A. How many leads are there on most transistors?

____

B. Where there are only two leads, what takes the place of the third lead?

____

C. What are the three leads or connections called?

____

D. Why should you take care when soldering transistors into a circuit?

____

Answers

A. Three.

B. The case can be used instead, as indicated in the diagram on the right side of Figure 3-1. (This type of case is used for power transistors.)

C. Emitter, base, and collector.

D. Excessive heat can damage a transistor.

2 You can think of a bipolar junction transistor as functioning like two diodes, connected back-to-back, as illustrated in Figure 3-2.

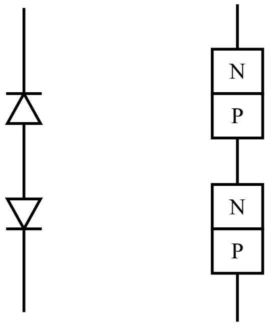

Figure 3-2

However, in the construction process, one very important modification is made. Instead of two separate P regions as shown in Figure 3-2, only one very thin region is used, as shown in Figure 3-3.

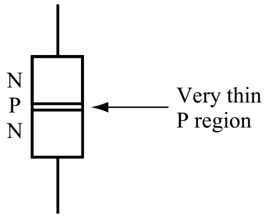

Figure 3-3

Question

Which has the thicker P region, the transistor shown in Figure 3-3 or two diodes connected back-to-back?

Answer

Two diodes. The transistor has a very thin P region.

3 Because two separate diodes wired back-to-back share two thick P regions, they will not behave like a transistor. The reason for this takes you into the realm of semiconductor physics, so it won't be covered in this book.

Question

Why don't two diodes connected back-to-back function like a transistor?

Answer

The transistor has one thin P region while the diodes share two thick P regions.

4 The three terminals of a transistor (the base, the emitter, and the collector) are connected as shown in Figure 3-4.

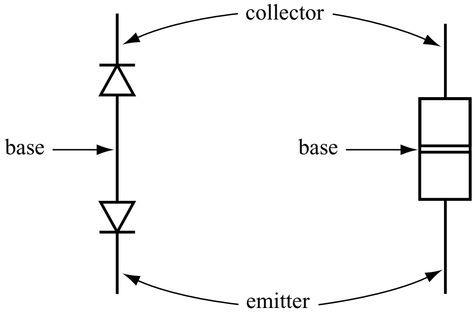

Figure 3-4

When talking about a transistor as two diodes, you refer to the diodes as the *base-emitter diode*, and the *base-collector diode*.

The symbol used in circuit diagrams for the transistor is shown in Figure 3-5, with the two diodes and the junctions shown for comparison. Because of the way the semiconductor materials are arranged, this is known as an NPN transistor.

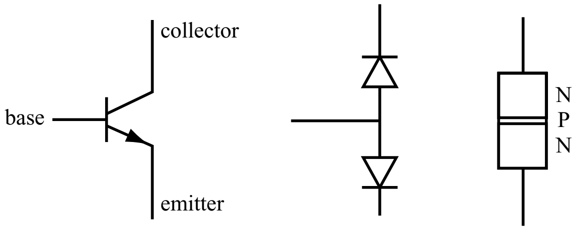

Figure 3-5

Question

Which transistor terminal includes an arrowhead?

Answer

The emitter

5 It is also possible to make transistors with a PNP configuration, as shown in Figure 3-6.

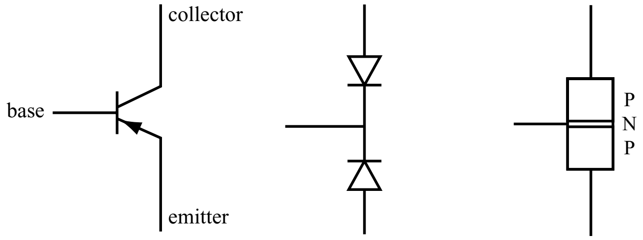

Figure 3-6

Both NPN and PNP type transistors can be made from either silicon or germanium.

Questions

A. Draw a circuit symbol for both an NPN and a PNP transistor. (Use a separate sheet of paper for your drawings.)

B. Which of the transistors represented by these symbols might be silicon?

____

C. Are silicon and germanium ever combined in a transistor?

____

Answers

A. See Figure 3-7.

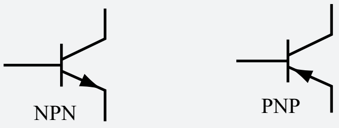

Figure 3-7

B. Either or both could be silicon. (Either or both could also be germanium.)

C. Silicon and germanium are *not* mixed in any commercially available transistors. However, researchers are attempting to develop ultrafast transistors that contain both silicon and germanium.

6 Take a look at the simple examples using NPN transistors in this and the next few problems.

If a battery is connected to an NPN transistor as shown in Figure 3-8, then a current will flow in the direction shown.

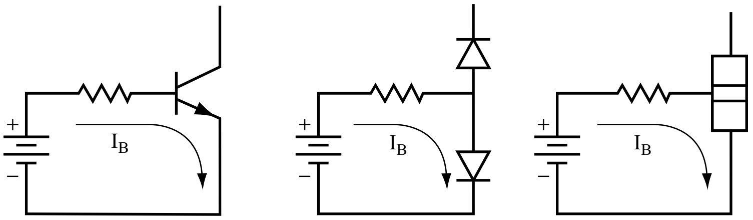

Figure 3-8

The current, flowing through the base-emitter diode, is called *base current* and is represented by the symbol I_B.

Question

Would base current flow if the battery were reversed? Give a reason for your answer.

____

Answer

Base current would not flow because the diode would be back-biased.

7 In the circuit in Figure 3-9, you can calculate the base current using the techniques covered in Chapter 2.

Question

Find the base current in the circuit shown in Figure 3-9. (*Hint:* Do not ignore the 0.7 V drop across the base-emitter diode.)

I_B = ____

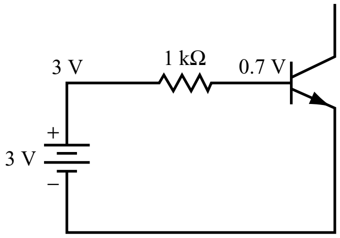

Figure 3-9

Answer

Your calculations should look something like this:

$$I_B = \frac{(V_S - 0.7\,V)}{R} = \frac{(3 - 0.7)}{1\,k\Omega} = \frac{2.3\,V}{1\,k\Omega} = 2.3\,mA$$

8 For the circuit shown in Figure 3-10, because the 10 volts supplied by the battery is much greater than the 0.7 V diode drop, you can consider the base-emitter diode to be a perfect diode, and thus assume the voltage drop is 0 V.

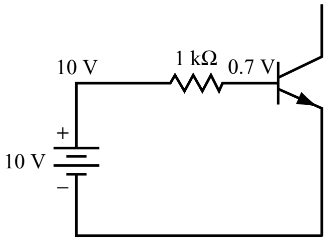

Figure 3-10

Question

Calculate the base current.

$I_B =$ ______________________________

Answer

$$I_B = \frac{(10 - 0)}{1\,k\Omega} = \frac{10}{1\,k\Omega} = 10\,mA$$

9 Look at the circuit shown in Figure 3-11.

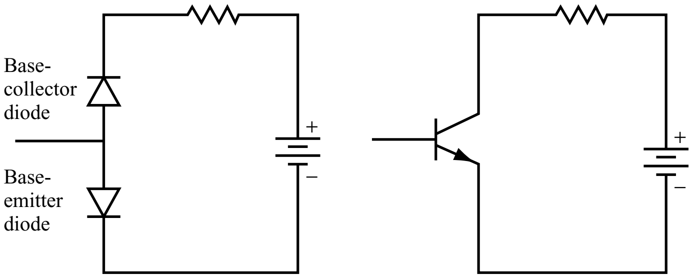

Figure 3-11

Question

Will current flow in this circuit? Why or why not?

Answer

It will not flow because the base-collector diode is reverse-biased.

10 Examine the circuit shown in Figure 3-12. Notice that batteries are connected to both the base and collector portions of the circuit.

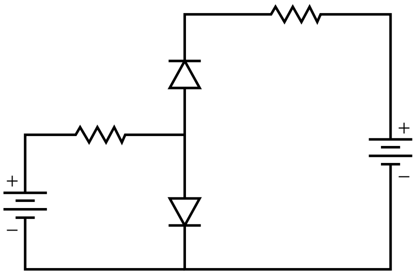

Figure 3-12

When you connect batteries to both the base and the collector portions of the circuit, currents flowing through the circuit demonstrate a key characteristic of the transistor. This characteristic is sometimes called *transistor action — if base current flows in a transistor, collector current will also flow*.

Examine the current paths shown in Figure 3-13.

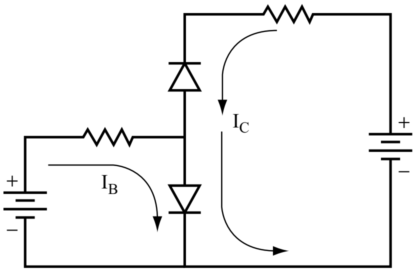

Figure 3-13

Questions

A. What current flows through the base-collector diode?

B. What current flows through the base-emitter diode?

C. Which of these currents causes the other to flow?

Answers

A. I_C (the collector current).

B. I_B and I_C. Note that both of them flow through the base-emitter diode.

C. Base current causes collector current to flow.

No current flows along the path shown by the dotted line in Figure 3-14 from the collector to the base.

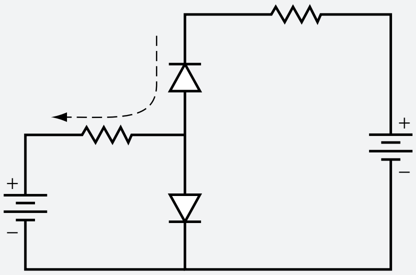

Figure 3-14

11 Up to now, you have studied the NPN bipolar transistor. PNP bipolar transistors work in the same way as NPN bipolar transistors, and can also be used in these circuits.

There is, however, one important circuit difference, which is illustrated in Figure 3-15. The PNP transistor is made with the diodes oriented in the reverse direction from the NPN transistor.

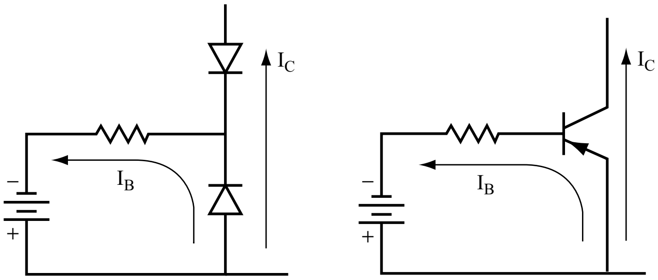

Figure 3-15

Questions

Compare Figure 3-15 with Figure 3-13. How are the circuits different relative to the following?

A. Battery connections:

B. Current flow:

Answers

A. The battery is reversed in polarity.

B. The currents flow in the opposite direction.

12 Figure 3-16 shows the battery connections necessary to produce both base current and collector current in a circuit that uses a PNP transistor.

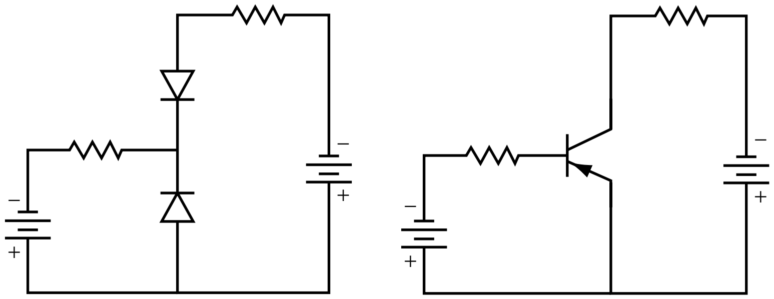

Figure 3-16

Question

In which direction do these currents circulate — clockwise or counterclockwise?

Answers

Base current flows counterclockwise.
Collector current flows clockwise.

As stated earlier, NPN and PNP bipolar transistors work in much the same way: Base current causes collector current to flow in both. The only significant difference in using a PNP versus an NPN bipolar transistor is that the polarity of the supply voltage (for both the base and collector sections of the circuit) is reversed. To avoid confusion, bipolar transistors used throughout the rest of this book are NPNs.

13 Consider the circuit in Figure 3-17. It uses only one battery to supply voltage to both the base and the collector portions of the circuit. The path of the base current is shown in the diagram.

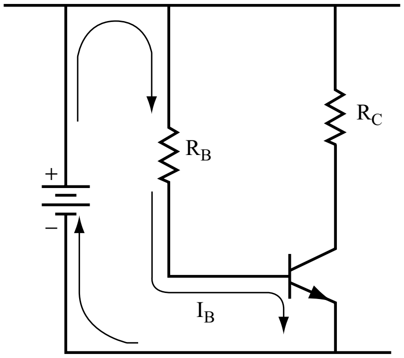

Figure 3-17

Questions

A. Name the components through which the base current flows.

B. Into which terminal of the transistor does the base current flow?

C. Out of which transistor terminal does the base current flow?

D. Through which terminals of the transistor does base current not flow?

Answers

A. The battery, the resistor R_B, and the transistor

B. Base

C. Emitter

D. Collector

14 Take a moment to recall the key physical characteristic of the transistor.

Question

When base current flows in the circuit shown in Figure 3-17, what other current will flow, and which components will it flow through?

Answer

Collector current will flow through the resistor R_C and the transistor.

15 In Figure 3-18 the arrows indicate the path of the collector current through the circuit.

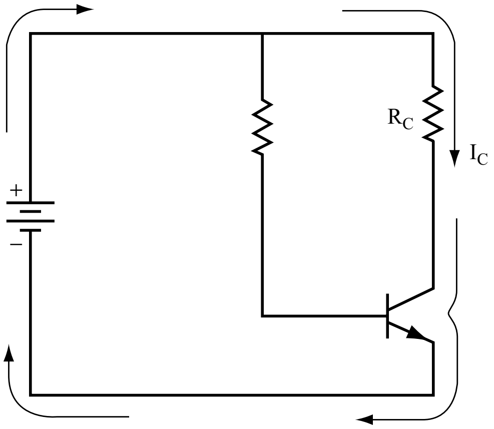

Figure 3-18

Questions

A. List the components through which the collector current flows.

B. What causes the collector current to flow?

Answers

A. The resistor R_C, the transistor, and the battery.

B. Base current. (Collector current doesn't flow unless base current is flowing.)

16 It is a property of the transistor that the *ratio of collector current to base current is constant*. The collector current is always much larger than the base current. The ratio of the two currents is called the *current gain* of the transistor and is represented by the symbol β, or beta. Typical values of β range from 10 to 300.

Questions

A. What is the ratio of collector current to base current called?

____

B. What is the symbol used to represent this?

____

C. Which is larger — base or collector current?

____

D. Look back at the circuit in problem 13. Will current be greater in R_B or in R_C?

____

Answers

A. Current gain

B. β

C. Collector current is larger.

D. The current is greater in R_C, because it is the collector current.

NOTE **The β introduced here is referred to in manufacturers' specification sheets as h_{FE}. Technically it is referred to as the static or DC β. For the purposes of this chapter, it is called β. Discussions on transistor parameters in general, which are well covered in many textbooks, will not be covered here.**

17 The mathematical formula for current gain is as follows:

$$\beta = \frac{I_C}{I_B}$$

where:

I_B = base current

I_C = collector current

The equation for β can be rearranged to give $I_C = \beta\, I_B$. From this, you can see that if no base current flows, no collector current flows. Also, if more base current flows, more collector current flows. This is why it's said that the ''base current controls the collector current.''

Question

Suppose the base current is 1 mA and the collector current is 150 mA. What is the current gain of the transistor?

Answer

150

18 Current gain is a physical property of transistors. You can find its value in the manufacturers' published data sheets, or you can determine it by experimenting.

In general, β is a different number from one transistor part number to the next, but transistors with the same part number have β values within a narrow range of each other.

One of the most frequently performed calculations in transistor work is to determine the values of either collector or base current, when β and the other current are known.

For example, suppose a transistor has 500 mA of collector current flowing and you know it has a β value of 100. Find the base current. To do this, use the following formula:

$$\beta = \frac{I_C}{I_B}$$

$$I_B = \frac{I_C}{\beta} = \frac{500\,\text{mA}}{100} = 5\,\text{mA}$$

Questions

Calculate the following values:

A. $I_C = 2$ A, $\beta = 20$. Find I_B.____________________

B. $I_B = 1$ mA, $\beta = 100$. Find I_C.____________________

C. $I_B = 10$ μA, $\beta = 250$. Find I_C.____________________

D. $I_B = 0.1$ mA, $I_C = 7.5$ mA. Find β.____________________

Answers

A. 0.1 A, or 100 mA

B. 100 mA

C. 2500 μA, or 2.5 mA

D. 75

19 This problem serves as a summary of the first part of this chapter. You should be able to answer all these questions. Use a separate sheet of paper for your drawing and calculations.

Questions

A. Draw a transistor circuit utilizing an NPN transistor, a base resistor, a collector resistor, and one battery to supply both base and collector currents. Show the paths of I_B and I_C.

B. Which current controls the other?

____

C. Which is the larger current, I_B or I_C?

____

D. $I_B = 6$ μA, $\beta = 250$. Find I_C.____________________

E. $I_c = 300$ μA, $\Omega = 50$. Find I_B.____________________

Answers

A. See Figure 3-17 and Figure 3-18.

B. I_B (base current) controls I_C (collector current).

C. I_C

D. 1.5 mA

E. 6 mA

The Transistor Experiment

20 The objective of the following experiment is to find β of a particular transistor by measuring several values of base current with the corresponding values of collector current. Next, divide the values of collector current by the values of the base current to determine β. The value of β will be almost the same for all the measured values of current. This demonstrates that β is a constant for a transistor.

While the circuit is set up, measure the collector voltage for each current value. This demonstrates (experimentally) some points that are covered in future problems. As you perform the experiment, observe how the collector voltage V_c drops toward 0 V as the collector current increases.

If you do not have the facilities for setting up the circuit and measuring the values, just read through the experiment. If you do have the facilities, you will need the following equipment and supplies.

- One 9 V transistor radio battery (or a lab power supply).
- One multimeter set to measure current on a scale that will measure at least 100 μA.
- One multimeter set to measure current on a scale that will measure at least 10 mA.
- One multimeter set to measure voltage, on a scale that will measure at least 10 V.
- One resistor substitution box, or a 1 MΩ potentiometer, or assorted resistors with the values listed in the following table. If you use a potentiometer, you'll need another multimeter to read its resistance after each adjustment.

R_B
1 MΩ
680 kΩ
470
330

R_B
270
220
200
180
160
150
120
110
100

- One 1 kΩ resistor.
- One transistor, preferably NPN.
- One breadboard.

Almost any small commercially available transistor will do for this experiment. The measurements given in this book were obtained using a 2 N3643. If only a PNP is available, then simply reverse the battery voltage and proceed as described.

Set up the circuit shown in Figure 3-19 on the breadboard. Using breadboards allows you to easily connect components in a circuit that you can then disassemble when testing is complete. You can then use the components and breadboard in the construction of your next circuit.

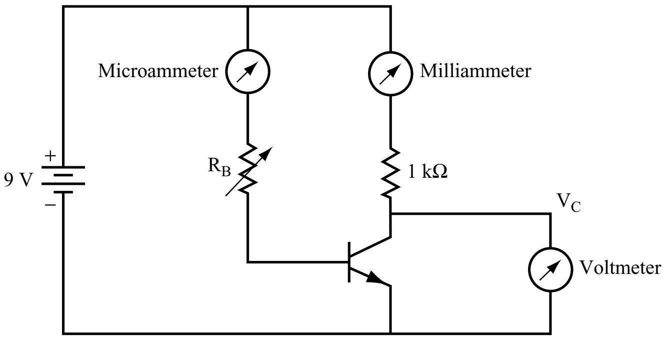

Figure 3-19

Follow these steps, recording your measurements in the following blank table.

R_B	I_B	I_C	V_C	β

1. Set R_B to its highest value.
2. Measure and record I_B
3. Measure and record I_C.
4. Measure and record V_C. This voltage is sometimes referred to as the *collector-emitter voltage* (V_{CE}), because it is taken across the collector-emitter leads if the emitter is connected to ground or the negative of the power supply.
5. Lower the value of R_B enough to produce a different reading of I_B.
6. Measure and record the new values for R_B, I_B, I_C, and V_C.
7. Lower R_B again and get a new I_B.
8. Measure and record the new values for R_B, I_B, I_C, and V_C again.
9. Repeat Steps 7 and 8 until $V_C = 0$ V.
10. Further reductions in the value of R_B will increase I_B, but will not affect the values of I_C or V_C.

Check the numbers in your table to make sure you got a consistent pattern. Then compare your measurements with the ones shown in the following table.

R_B	I_B	I_C	V_C	β
1 MΩ	9 μA	0.9 mA	8.1 volts	100
680 kΩ	13	1.3	7.7	100
470	19	1.9	7.1	100
330	27.3	2.8	6.2	103
270	33.3	3.3	5.7	99
220	40	4.1	5.0	103
200	45	4.5	4.5	100
180	50	5	4.0	100
160	56	5.6	3.4	100
150	60	6	3	100
120	75	7.5	1.5	100
110	82	8.0	1.0	98
100	90	9	0.3	100

The measurements shown here were obtained by conducting this experiment very carefully. Precision resistors and a commercial 2 N3643 transistor were used. With ordinary +/− 5 percent tolerance resistors and a transistor chosen at random, you could get different results. Don't worry if your results are not as precise as those listed here.

Calculation of β results in values at or very close to 100 for each measurement, which agrees with the manufacturer's specification of β = 100.

For each value of I_B and its corresponding value of I_C in your experiment, calculate the value of β ($\beta = I_C/I_B$). The values will vary slightly but will be close to an average. (Excessively low and high values of I_B may produce values of β, which will be quite different. Ignore these for now.) Did you get a consistent β? Was it close to the manufacturer's specifications for your transistor?

21 In the experiment, you measured the voltage level at the collector (V_C) and recorded your measurements. Now, examine how to determine the voltage at the collector, when it's not possible to measure the voltage level.

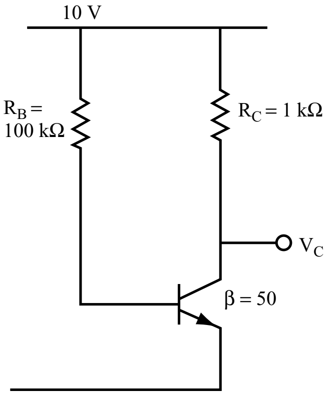

Figure 3-20

Use the values shown in the circuit in Figure 3-20 to complete these steps.

1. Determine I_C.
2. Determine the voltage drop across the collector resistor R_C. Call this V_R.
3. Subtract V_R from the supply voltage to calculate the collector voltage.

Here is the first step:

1. To find I_C, you must first find I_B.

$$I_B = \frac{10\,\text{V}}{100\,\text{k}\Omega} = 0.1\,\text{mA}$$

$$I_C = \beta \times I_B = 50 \times 0.1\,\text{mA} = 5\,\text{mA}$$

Now, perform the next two steps.

Questions

2. $V_R =$ ______________
3. $V_C =$ ______________

Answers

2. To find V_R:

   $V_R = R_C \times I_C = 1\ \text{k}\Omega \times 5\ \text{mA} = 5\ \text{V}$
3. To find V_C:

   $V_C = V_S - V_R = 10\ \text{V} - 5\ \text{V} = 5\ \text{V}$

22 Determine parameters for the circuit shown in Figure 3-20, using the value of $\beta = 75$.

Questions

Calculate the following:

A. $I_C =$ ____________________

B. $V_R =$ ____________________

C. $V_C =$ ____________________

Answers

A. $I_B = \frac{10\,V}{100\,k\Omega} = 0.1\,mA$

$I_C = 75 \times 0.1\,mA = 7.5\,mA$

B. $V_R = 1\,k\Omega \times 7.5\,mA = 7.5\,V$

C. $V_C = 10\,V - 7.5\,V = 2.5\,V$

23 Determine parameters for the same circuit, using the values of $R_B = 250\,k\Omega$ and $\beta = 75$.

Questions

Calculate the following:

A. $I_C =$ ____________________

B. $V_R =$ ____________________

C. $V_C =$ ____________________

Answers

A. $I_B = \frac{10\,V}{250\,k\Omega} = \frac{1}{25}\,mA$

$I_C = 75 \times \frac{1}{25}\,mA = 3\,mA$

B. $V_R = 1\,k\Omega \times 3\,mA = 3\,V$

C. $V_C = 10\,V - 3\,V = 7\,V$

24 From the preceding problems, you can see that you can set V_C to any value by choosing a transistor with an appropriate value of β, or by choosing the correct value of R_B.

Now, consider the example shown in Figure 3-21. The objective is to find V_C. Use the steps outlined in problem 21.

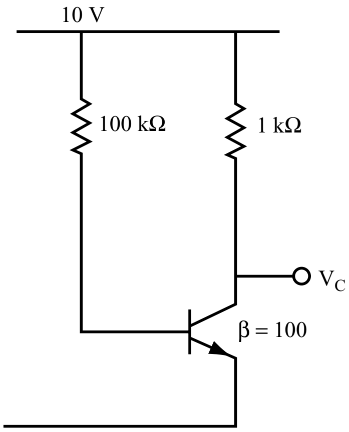

Figure 3-21

Questions

Calculate the following:

A. $I_B =$ ____________________

$I_C =$ ____________________

B. $V_R =$ ____________________

C. $V_C =$ ____________________

Answers

Your results should be as follows:

A. $I_B = \frac{10\,\text{V}}{100\,\text{k}\Omega} = 0.1\,\text{mA}$

$I_C = 100 \times 0.1\text{mA} = 10\,\text{mA}$

B. $V_R = 1\ \text{k}\Omega \times 10\ \text{mA} = 10\ \text{V}$

C. $V_C = 10\ \text{V} - 10\ \text{V} = 0\ \text{V}.$

Here, the base current is sufficient to produce a collector voltage of 0 volts and the maximum collector current possible, given the stated values of the collector resistor and supply voltage. This condition is called *saturation*.

25 Look at the two circuits shown in Figure 3-22 and compare their voltages at the point labeled V_C.

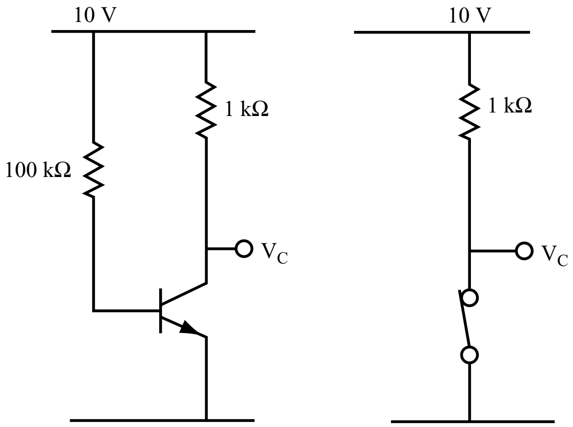

Figure 3-22

Consider a transistor that has sufficient base current and collector current to set its collector voltage to 0 V. Obviously, this can be compared to a closed mechanical switch. Just as the switch is said to be ON, then the transistor is also said to be ''turned on,'' or just ON.

Questions

A. What can you compare a turned on transistor to?

____

B. What is the collector voltage of an ON transistor?

____

Answers

A. A closed mechanical switch

B. 0 V

26 Now, compare the circuits shown in Figure 3-23.

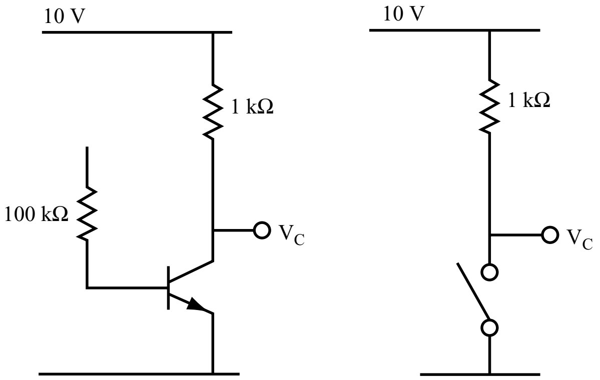

Figure 3-23

Because the base circuit is broken (that is, it is not complete), there is no base current flowing.

Questions

A. How much collector current is flowing?

____

B. What is the collector voltage?

____

C. What is the voltage at the point V_C in the mechanical switch circuit?

____

Answers

A. None.

B. Because there is no current flowing through the 1 kΩ resistor, there is no voltage drop across it, so the collector is at 10 V.

C. 10 V, because there is no current flowing through the 1 kΩ resistor.

27 From problem 26, it is obvious that a transistor with no collector current is similar to an open mechanical switch. For this reason, a transistor with no collector current and its collector voltage at the supply voltage level is said to be ''turned off,'' or just OFF.

Question

What are the two main characteristics of an OFF transistor?

____

Answer

It has no collector current, and the collector voltage is equal to the supply voltage.

28 Now, calculate the following parameters for the circuit in Figure 3-24 and compare the results to the examples in problems 26 and 27. Again, the objective here is to find V_C.

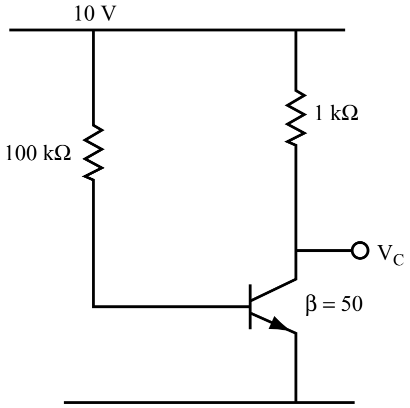

Figure 3-24

Questions

A. $I_B =$ ____

$I_C =$ ____

B. $V_R =$ ____

C. $V_C =$ ____

Answers

A. $I_B = \dfrac{10\,\text{V}}{100\,\text{k}\Omega} = 0.1\,\text{mA}$

$I_C = 50 \times 0.1\text{mA} = 5\text{mA}$

B. $V_R = 1\ \text{k}\Omega \times 5\ \text{mA} = 5\ \text{V}$

C. $V_C = 10\ \text{V} - 5\ \text{V} = 5\ \text{V}$

NOTE **The output voltage in this problem is exactly half the supply voltage. This condition is very important in AC electronics and is covered in Chapter 8.**

The Junction Field Effect Transistor

29 Up to now, the only transistor described was the bipolar junction transistor (BJT). Another common transistor type is the junction field effect transistor (JFET). The JFET, like the BJT, is used in many switching and amplification applications. The JFET is preferred when a high input impedance circuit is needed. The BJT has a relatively low input impedance as compared to the JFET. Like the BJT, the JFET is a three terminal device. The terminals are called the source, drain, and gate. They are similar in function to the emitter, collector, and base, respectively.

Questions

A. How many terminals does a JFET have, and what are these terminals called?

____

B. Which terminal has a function similar to the base of a BJT?

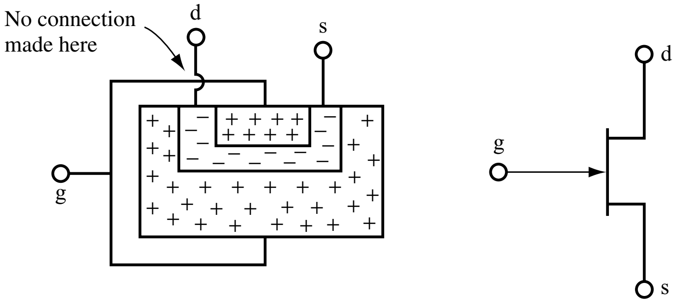
____

Answer

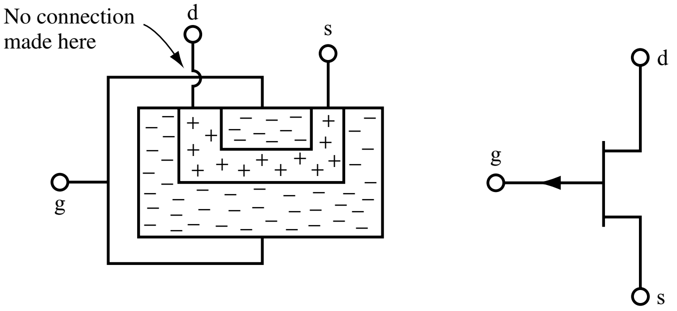
A. Three, called the source, drain, and gate.

B. The gate has a control function similar to that of the base of a BJT.

30 The basic design of a JFET consists of one type of semiconductor material with a channel made of the opposite type of semiconductor material running through it. If the channel is N material, it is called an N-channel JFET; if it is P material, it is called a P-channel. Figure 3-25 shows the basic layout of N and P materials, along with their circuit symbols. Voltage on the gate controls the current flow through the drain and source by controlling the effective width of the channel, allowing more or less current to flow. Thus, the voltage on the gate acts to control the drain current, just as the voltage on the base of a BJT acts to control the collector current.



N-channel JFET



P-channel JFET

Figure 3-25

Questions

A. Which JFET would use electrons as the primary charge carrier for the drain current?

B. What effect does changing the voltage on the gate have on the operation of the JFET?

Answers

A. N-channel, because N material uses electrons as the majority carrier.

B. It changes the current in the drain. The channel width is controlled electrically by the gate potential.

31 To operate the N-channel JFET, apply a positive voltage to the drain with respect to the source. This allows a current to flow through the channel. If the gate is at 0 V, the drain current is at its largest value for safe operation, and the JFET is in the ON condition. When a negative voltage is applied to the gate, the drain current is reduced. As the gate voltage becomes more negative, the current lessens until cutoff, which occurs when the JFET is in the OFF condition. Figure 3-26 shows a typical biasing circuit for the N-channel JFET. For a P-channel JFET, you must reverse the polarity of the bias supplies.

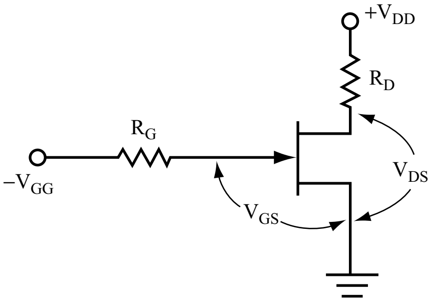


Figure 3-26

Question

How does the ON-OFF operation of a JFET compare to that of a BJT?

Answer

The JFET is ON when there are 0 volts on the gate, whereas you turn the BJT ON by applying a voltage to the base. You turn the JFET OFF by applying a voltage to the gate, and the BJT is OFF when there are 0 volts on the base. The JFET is a ''normally ON'' device, but the BJT is considered a ''normally OFF'' device. Therefore you can use the JFET (like the BJT) as a switching device.

32 When the gate to source voltage is at 0 V ($V_{GS} = 0$) for the JFET shown in Figure 3-26, the drain current is at its maximum or saturation value. This means that the N-channel resistance is at its lowest possible value, in the range of 5 to 200 ohms. If R_D is significantly greater than this, the N-channel resistance, r_{DS}, is assumed to be negligible.

Questions

A. What switch condition would this represent, and what will be the drain to source voltage (V_{DS})?

B. As the gate becomes more negative with respect to the source, the resistance of the N-channel increases until the cutoff point is reached. At this point the resistance of the channel is assumed to be infinite. What condition will this represent, and what will be the drain to source voltage?

C. What does the JFET act like when it is operated between the two extremes of current saturation and current cutoff?

Answers

A. Closed switch, $V_{DS} = 0$ V, or very low value

B. Open switch, $V_{DS} = V_{DD}$

C. A variable resistance

Summary

At this point, it's useful to compare the properties of a mechanical switch with the properties of both types of transistors, as summarized in the following table.

SWITCH	BJT	JFET
OFF or open		
No current	No collector current	No drain current
Full voltage across terminals	Full supply voltage between collector and emitter	Full supply voltage between drain and source
ON or closed		
Full current	Full circuit current	Full circuit current
No voltage across terminals	Collector to emitter voltage is 0 V	Drain to source voltage is 0 V

The terms ON and OFF are used in digital electronics to describe the two transistor conditions you just encountered. Their similarity to a mechanical switch is useful in many electronic circuits. In Chapter 4,you learn about the transistor switch in more detail. This is the first step toward an understanding of digital electronics. In Chapter 8,you examine the operation of the transistor when it is biased at a point falling between the two conditions, ON and OFF. In this mode, the transistor can be viewed as a variable resistance, and utilized as an amplifier.

Self-Test

The questions here test your understanding of the concepts presented in this chapter. Use a separate sheet of paper for your drawings or calculations. Compare your answers with the answers provided following the test.

1. Draw the symbols for an NPN and a PNP bipolar transistor. Label the terminals of each.
2. In Figure 3-27, draw the paths taken by the base and collector currents.

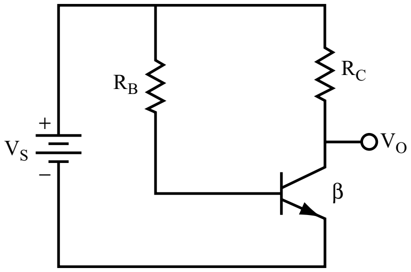

Figure 3-27

3. What causes the collector current to flow?

____

4. What is meant by the term *current gain*? What symbol is used for this? What is its algebraic formula?

____

Use the circuit in Figure 3-27 to answer questions 5 through 10.

5. Assume that the transistor is made of silicon. Set $R_B = 27\ k\Omega$ and $V_s = 3$ V. Find I_B.

____

6. If $R_B = 220\ k\Omega$ and $V_S = 10$ V. Find I_B.

7. Find V_O when $R_B = 100\ k\Omega$, $V_S = 10$ V, $R_C = 1\ k\Omega$, and $\beta = 50$.

8. Find V_O when $R_B = 200\ k\Omega$, $V_S = 10$ V, $R_C = 1\ k\Omega$, and $\beta = 50$.

9. Now use these values to find V_O: $R_B = 47\ k\Omega$, $V_S = 10$ V, $R_C = 500$ ohms, and $\beta = 65$.

10. Use these values to find V_O: $R_B = 68\ k\Omega$, $V_S = 10$ V, $R_C = 820$ ohms, and $\beta = 75$.

11. Draw the symbols for the two types of junction field effect transistors and identify the terminals.

12. What controls the flow of current in both a JFET and a BJT?

13. In the JFET common source circuit shown in Figure 3-28, add the correct polarities of the power supplies and draw the current path taken by the drain current.

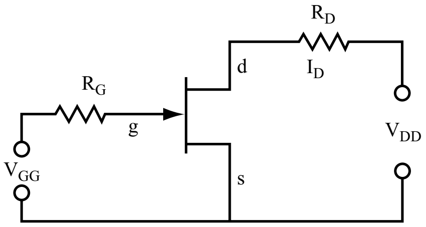

Figure 3-28

14. When a base current is required to turn a BJT ON, why is there no gate current for the JFET in the ON state.

15. Answer the following questions for the circuit shown in Figure 3-29.

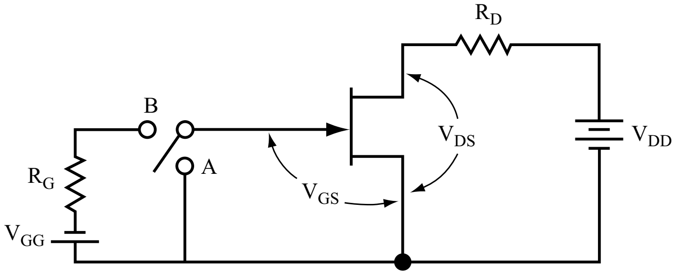

Figure 3-29

A. If the switch is at position A, what will the drain current be, and why? ______________________

B. If the switch is at position B, and the gate supply voltage is of sufficient value to cause cutoff, what will the drain current be, and why? ______________________

C. What is the voltage from the drain to the source for the two switch positions? ______________________

Answers to Self-Test

If your answers do not agree with those given below, review the problems indicated in parentheses before you go on to the next chapter.

---

1. See Figure 3-30. (problems 4, 5)

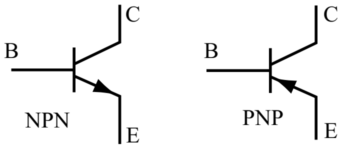

Figure 3.30

2.	See Figure 3-31.	(problems 13,15)

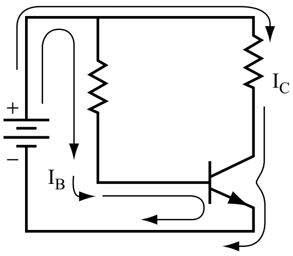

Figure 3.31

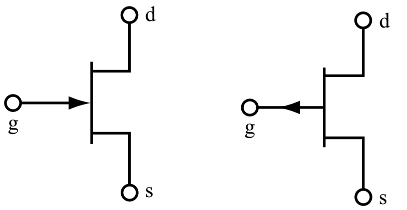
3.	Base current.	(problem 15)
4.	Current gain is the ratio of collector current to base current. It is represented by the symbol β. β = I_C/I_B.	(problems 16, 17)
5.	$I_B = \frac{(V_S - 0.7)}{R_B} = \frac{(3V - 0.7V)}{27k\Omega} = \frac{2.3V}{27k\Omega} = 85\mu\ A$	(problem 7)
6.	$I_B = \frac{10V}{220k\Omega} = 45.45\mu A$	(problem 7)
7.	5 V	(problem 21–24)
8.	7.5 V	(problem 21–24)
9.	3.1 V	(problem 21–24)
10.	1 V	(problem 21–24)
11.	See Figure 3-32.	(problem 30)



N-channel P-channel

Figure 3.32

12.		The voltage on the gate controls the flow of drain current, which is similar to the base voltage controlling the collector current in a BJT.	(problem 30)
13.		See Figure 3-33.	(problem 31)
		 **Figure 3.33**	
14.		The JFET is a high-impedance device and does not draw current from the gate circuit. The BJT is a relatively low-impedance device and does, therefore, require some base current to operate.	(problem 29)
15.	A.	The drain current will be at its maximum value. In this case, it equals V_{DD}/R_D because you can ignore the drop across the JFET. The gate to source voltage is 0 V, which reduces the channel resistance to a very small value close to 0 ohms.	(problem 3-32)
	B.	The drain current now goes to 0 A because the channel resistance is at infinity (very large), which does not allow electrons to flow through the channel.	
	C.	At position A, V_{DS} is approximately 0 V. At position B, $V_{DS} = V_{DD}$.	

CHAPTER 4

The Transistor Switch

Transistors are everywhere. You can't avoid them as you move through your daily tasks. For example, almost all industrial controls, and even your MP3 player, stereo, and television may use transistors as switches.

In Chapter 3, you saw how a transistor can be turned ON and OFF, similar to a mechanical switch. Computers work with Boolean algebra, which uses only two logic states — TRUE and FALSE. These two states are easily represented electronically by a transistor that is ON or OFF. Therefore, the transistor switch is used extensively in computers. In fact, the logic portions of microprocessors (the brains of computers) consist entirely of transistor switches.

This chapter introduces the transistor's simple and widespread application–switching, with emphasis on the bipolar junction transistor (BJT).

When you complete this chapter, you will be able to do the following:

- Calculate the base resistance, which turns a transistor ON and OFF.
- Explain how one transistor will turn another ON and OFF.
- Calculate various currents and resistances in simple transistor switching circuits.
- Calculate various resistances and currents in switching circuits, which contain two transistors.
- Compare the switching action of a junction field effect transistor (JFET) to a BJT.

Turning the Transistor on

1 Start by examining how to turn a transistor ON by using the simple circuit shown in Figure 4-1. In Chapter 3, R_B was given, and you had to find the value of collector current and voltages. Now, do the reverse. Start with the current through R_C and find the value of R_B that will turn the transistor ON and permit the collector current to flow.

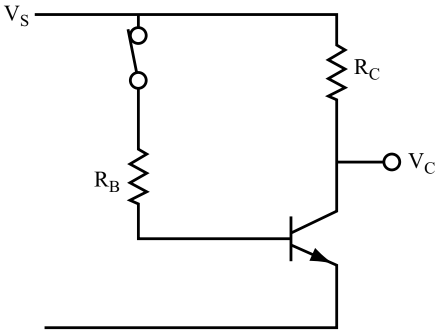


Figure 4-1

Question

What current values do you have to know in order to find R_B?

Answer

The base and collector currents

2 In this problem circuit, a lamp can be substituted for the collector resistor. In this case, R_C (the resistance of the lamp) is referred to as the *load*, and I_C (the current through the lamp) is called the *load current*.

Questions

A. Is load current equivalent to base or collector current?

B. What is the path taken by the collector current discussed in problem 1? Draw this path on the circuit.

Answers

A. Collector current

B. See Figure 4-2. In this figure, note that the resistor symbol has been replaced by the symbol for an incandescent lamp.

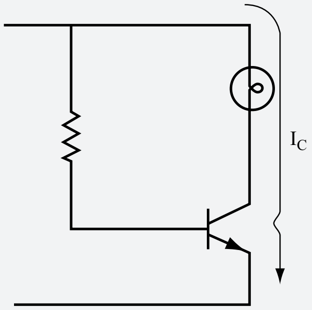

Figure 4-2

3 For the transistor switch to perform effectively as a CLOSED switch, its collector voltage must be at the same voltage as its emitter voltage. In this condition, the transistor is said to be turned ON.

Questions

A. What is the collector voltage when the transistor is turned ON?

____

B. What other component does an ON transistor resemble?

____

Answers

A. The same as the emitter voltage, which, in this circuit, is 0 volts

B. A closed mechanical switch

NOTE **In actual practice, there is a very small voltage drop across the transistor from the collector to the emitter. This is really a saturation voltage and is the smallest voltage drop that can occur across a transistor when it is ON as "hard" as possible. The discussions in this chapter consider this voltage drop to be a negligible value and, therefore, the collector voltage is said to be 0 V. For a quality switching transistor, this is a safe assumption.**

4 The circuit in Figure 4-3 shows a lamp with a resistance of 240 ohms in place of R_C.

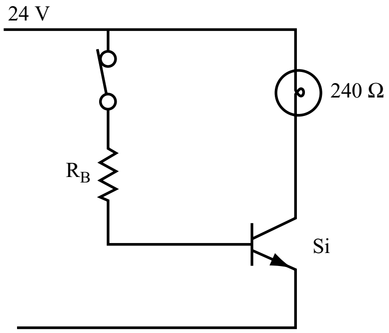

Figure 4-3

This figure shows the supply voltage and the collector resistance. Given these two values, using Ohm's law, you can calculate the load current (also called the *collector current*) as follows:

$$I_L = I_C = \frac{V_S}{R_C} = \frac{24\text{ V}}{240\text{ ohms}} = 100\text{ mA}$$

Thus, 100 mA of collector current must flow through the transistor to fully illuminate the lamp. As you learned in Chapter 3, collector current will not flow unless base current is flowing.

Questions

A. Why do you need base current?

____

B. How can you make base current flow?

____

Answers

A. To enable collector current to flow, so that the lamp will light up

B. By closing the mechanical switch in the base circuit

5 You can calculate the amount of base current flowing. Assume that $\beta = 100$. (Normally, you would look this up in the manufacturer's datasheet for the transistor you are using.)

Questions

A. What is the value of the base current I_B?

____

Answer

$$I_B = \frac{I_C}{\beta} = \frac{100\,\text{mA}}{100} = 1\,\text{mA}$$

6 The base current flows in the direction shown in Figure 4-4. Base current flows through the base-emitter junction of the transistor as it does in a forward-biased diode.

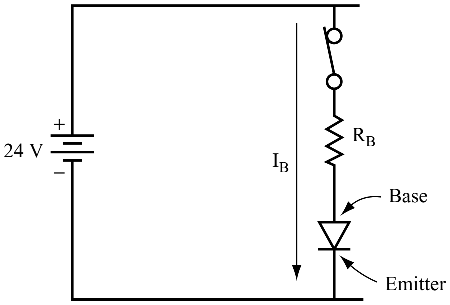

Figure 4-4

Questions

A. What is the voltage drop across the base-emitter diode?

____

B. What is the voltage drop across R_B?

____

Answers

A. 0.7 V, because it is a silicon transistor

B. 24 V if the 0.7 is ignored; 23.3 V if it is not

7 The next step is to calculate R_B. The current flowing through R_B is the base current I_B, and you determined the voltage across it in problem 6.

Question

Calculate R_B.

Answer

$$R_B = \frac{23.3\text{ V}}{1\text{ mA}} = 23,300\,\text{ohms}$$

The final circuit, including the calculated current and resistance values, is shown in Figure 4-5.

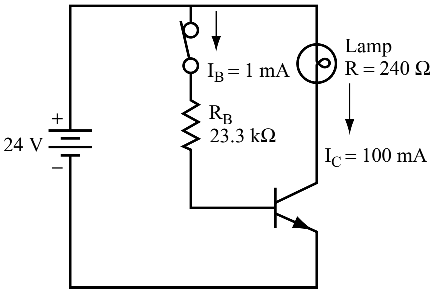

Figure 4-5

8 Use the following steps to calculate the values of I_B and R_B needed to turn a transistor ON:

1. Determine the required collector current.
2. Determine the value of β.
3. Calculate the required value of I_B from the results of steps 1 and 2.
4. Calculate the required value of R_B.
5. Draw the final circuit.

Now, assume that $V_S = 28$ V, that you are using a lamp requiring 50 mA of current, and that $\beta = 75$.

Questions

A. Calculate I_B.

B. Determine R_B.

Answers

A. The collector current and β were given. Thus:

$$I_B = \frac{I_C}{\beta} = \frac{50\,\text{mA}}{75} = 0.667\,\text{mA}$$

B. $R_B = \dfrac{28\,\text{V}}{0.667\,\text{mA}} = 42\,\text{k}\Omega$

This calculation ignores V_{BE}.

9 Now, assume that $V_S = 9$ V, that you are using a lamp requiring 50 mA of current, and that $\beta = 75$.

Question

Calculate R_B.

Answer

$R_B = 31.1\,\text{k}\Omega$

In this calculation, V_{BE} is included.

10 In practice, if the supply voltage is much larger than the 0.7 V drop across the base-emitter junction, you can simplify your calculations by ignoring the 0.7 V drop and assume that all the supply voltage appears across the base resistor R_B. (Most resistors are only accurate to within $+/-5$ percent of their stated value anyway.) If the supply voltage is less than 10 volts, however, you shouldn't ignore the 0.7 V drop across the base-emitter junction.

Questions

Calculate R_B for the following problems, ignoring the voltage drop across the base-emitter junction, if appropriate.

A. A 10 V lamp that draws 10 mA. $\beta = 100$.

B. A 5 V lamp that draws 100 mA. β = 50.

Answers

A. $$I_B = \frac{10\,\text{mA}}{100} = 0.1\,\text{mA}$$

$$R_B = \frac{10\,\text{V}}{0.1\,\text{mA}} = 100\,\text{k}\Omega$$

B. $$I_B = \frac{100\,\text{mA}}{50} = 2\,\text{mA}$$

$$R_B = \frac{(5\,\text{V} - 0.7\,\text{V})}{2\,\text{mA}} = \frac{4.3\,\text{V}}{2\,\text{mA}} = 2.15\,\text{k}\Omega$$

Turning the Transistor off

11 Up to now, you have concentrated on turning the transistor ON, thus making it act like a closed mechanical switch. Now you focus on turning it OFF, thus making it act like an open mechanical switch. If the transistor is OFF, no current flows through the load (that is, no collector current flows).

Questions

A. When a switch is open, are the two terminals at different voltages, or at the same voltage?

B. When a switch is open, does current flow?

C. For a transistor to turn OFF and act like an open switch, how much base current is needed?

Answers

A. At different voltages, the supply voltage and ground voltage.

B. No.

C. The transistor is OFF when there is no base current.

12 You can be sure that there is no base current in the circuit shown in Figure 4-6 by opening the mechanical switch.

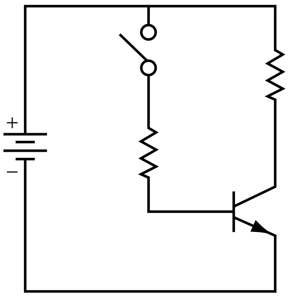

Figure 4-6

To ensure that the transistor remains off when the base is not connected to the supply voltage you add a resistor (labeled R_2 in Figure 4-7) to the circuit. The base of the transistor is connected to ground or 0 volts through this resistor. Therefore, no base current can possibly flow.

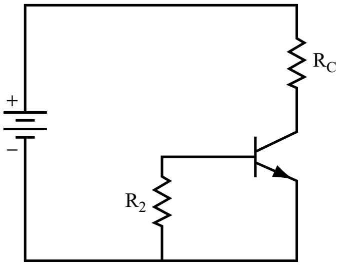

Figure 4-7

Questions

A. Why will current not flow from the supply voltage to the base-emitter junction?

____

B. How much current flows from collector to base?

C. Why will current not flow from collector to base through R_2 ground?

D. Why is the transistor base at 0 volts when R_2 is installed?

Answers

A. There is no current path from the supply voltage through the base-emitter junction. Thus, there is no base current flowing.

B. None at all.

C. The internal construction of the transistor prevents this, because the collector-to-base junction is basically a reverse-biased diode.

D. Because there is no current through R_2, there is no voltage drop across R_2 and, therefore, the transistor base is at ground (0 volts).

13 Because no current is flowing through R_2, you can use a wide range of resistance values. In practice, the values you find for R_2 will be between 1 kΩ and 1 MΩ.

Question

Which of the following resistor values would you use to keep a transistor turned off? 1 ohm, 2 kΩ, 10 kΩ, 20 kΩ, 50 kΩ, 100 kΩ, 250 kΩ, 500 kΩ.

Answer

They would all be suitable except the 1 ohm, because the rest are all above 1 kΩ and below 1 MΩ.

14 Figure 4-8 shows a circuit using both R_1 and R_2. Note that the circuit includes a two-position switch that you can use to turn the transistor ON or OFF.

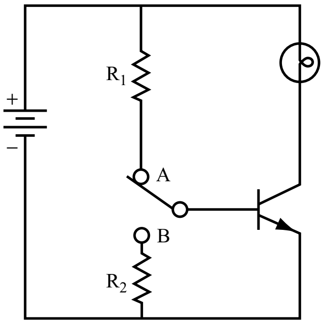

Figure 4-8

Questions

A. As shown in Figure 4-8, is the transistor ON or OFF?

____

B. Which position, A or B, will cause the collector current to be 0 amperes?

____

Answers

A. ON — the base-to-emitter diode is forward biased. Therefore, base current can flow.

B. Position B — the base is tied to ground. Therefore, no base current can flow, and the transistor is OFF.

Why Transistors are Used as Switches

15 You can use the transistor as a switch (as you saw in the previous problems) to perform simple operations such as turning a lamp current on and off. Although often used between a mechanical switch and a lamp, there are other uses for the transistor.

Following are a few other examples that demonstrate the advantages of using a transistor in a circuit as a switch:

- *Example 1* — Suppose you have to put a lamp in a dangerous environment, such as a radioactive chamber. Obviously, the switch to operate the lamp must be placed somewhere safe. You can simply use a switch outside the chamber to turn the transistor switch ON or OFF.

- *Example 2* — If a switch controls equipment that requires large amounts of current, then that current must flow through the wires that run between the switch and the lamp. Because the transistor switch can be turned ON or OFF using low voltages and currents, you can connect a mechanical switch to the transistor switch using small, low-voltage wire and, thereby, control the larger current flow. If the mechanical switch is any distance from the equipment you're controlling, using low-voltage wire will save you time and money.
- *Example 3* — A major problem with switching high current in wires is that the current induces interference in adjacent wires. This can be disastrous in communications equipment such as radio transceivers. To avoid this, you can use a transistor to control the larger current from a remote location, reducing the current needed at the switch that is located in the radio transceiver.
- *Example 4* — In mobile devices (such as a radio controlled airplane), using transistor switches minimizes the power, weight, and bulk required.

Question

What features mentioned in these examples make using transistors as switches desirable?

Answer

The switching action of a transistor can be directly controlled by an electrical signal, as well as by a mechanical switch in the base circuit. This provides a lot of flexibility to the design and allows for simple electrical control. Other factors include safety, reduction of interference, remote switching control, and lower design costs.

16 The following examples of transistor switching demonstrate some other reasons for using transistors:

- *Example 1* — You can control the ON and OFF times of a transistor very accurately, while mechanical devices are not very accurate. This is most important in applications such as photography, where it is necessary to expose a film or illuminate an object for a precise period of time. In these types of uses, transistors are much more accurate and controllable than any other device.

- *Example 2* — A transistor can be switched ON and OFF millions of times a second, and will last for many years. In fact, transistors are one of the longest lasting and most reliable components known, while mechanical switches usually fail after a few thousand operations.
- *Example 3* — The signals generated by most industrial control devices are digital. These control signals can be simply a high or low voltage, which is ideally suited to turning transistor switches ON or OFF.
- *Example 4* — Modern manufacturing techniques allow for the miniaturization of transistors to such a great extent that many of them (even hundreds of millions) can be fabricated into a single silicon chip. Silicon chips on which transistors (and other electronic components) have been fabricated are called *integrated circuits* (ICs). ICs are little flat, black plastic components built into almost every mass-produced electronic device, and are the reason that electronic devices continue to get smaller and lighter.

Question

What other features, besides the ones mentioned in the previous problem, are demonstrated in the examples given here?

Answer

Transistors can be accurately controlled, have high-speed operation, are reliable, have a long life, are very small, have low power consumption, can be manufactured in large numbers at low cost, and are extremely small.

17 At this point, consider the idea of using one transistor to turn another one ON and OFF, and using the second transistor to operate a lamp or other load. (This idea is explored in the next section of this chapter.)

If you have to switch many high current loads, then you can use one switch that controls several transistors simultaneously.

Questions

A. With the extra switches added, will the current that flows through the main switch be more or less than the current that flows through the load?

B. What effect do you think the extra transistor will have on the following?

1. Safety

____

2. Convenience to the operator

____

3. Efficiency and smoothness of operation

____

Answers

A. Less current will flow through the main switch than through the load.

B.
1. It increases safety and allows the operator to stay isolated from dangerous situations.
2. Switches can be placed conveniently close together on a panel, or in the best place for an operator, rather than the switch position dictating operator position.
3. One switch can start many things, as in a master lighting panel in a television studio or theater.

18 This problem reviews your understanding of the concepts presented in problems 15, 16, and 17.

Questions

Indicate which of the following are good reasons for using a transistor as a switch:

A. To switch equipment in a dangerous or inaccessible area on and off

B. To switch very low currents or voltages

C. To lessen the electrical noise that might be introduced into communication and other circuits

D. To increase the number of control switches

E. To use a faster, more reliable device than a mechanical switch

____

Answers

A, C, and E.

19 Many types of electronic circuits contain multiple switching transistors. In this type of circuit, one transistor is used to switch others ON and OFF. To illustrate how this works, again consider the lamp as the load and the mechanical switch as the actuating element. Figure 4-9 shows a circuit that uses two transistors to turn a lamp on or off.

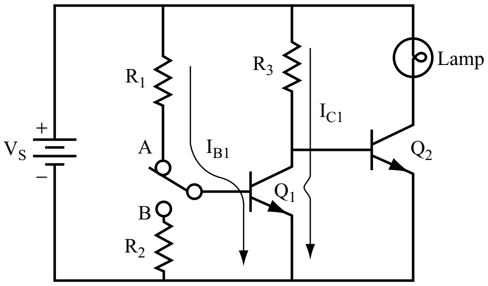

Figure 4-9

When the switch is in position A, Q_1's base-emitter junction is forward biased. Therefore, base current (I_{B1}) flows through R_1 and through Q_1's base-emitter diode, turning the transistor ON. This causes the collector current (I_{C1}) to flow through Q_1 to ground, and the collector voltage drops to 0 volts, just as if Q_1 was a closed switch. Because the base of Q_2 is connected to the collector of Q_1, the voltage on the base of Q_2 also drops to 0 volts. This ensures that Q_2 is turned OFF and the lamp remains unlit.

Now, flip the switch to position B, as shown in Figure 4-10. The base of Q_1 is tied to ground, or 0 volts, turning Q_1 OFF. Therefore, no collector current can flow through Q_1. A positive voltage is applied to the base of Q_2 and Q_2's emitter-base junction is forward biased. This allows current to flow through R_3 and the emitter-base junction of Q_2, which turns Q_2 ON, allowing collector current (IC_2) to flow and the lamp is illuminated.

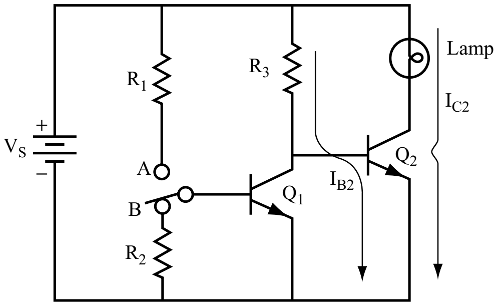

Figure 4-10

Now that you have read the descriptions of how the circuit works, try to answer the following questions. First assume the switch is in position A, as shown in Figure 4-9.

Questions

A. What effect does I_{B1} have on transistor Q_1?

____

B. What effect does turning Q_1 ON have on

1. Collector current I_{C1}?

   ____

2. Collector voltage V_{C1}?

   ____

C. What effect does the change to V_{C1} covered in the previous question have on

1. The base voltage of Q_2?

   ____

2. Transistor Q_2 (that is, is it ON or OFF)?

   ____

D. Where does the current through R_3 go?

____

E. In this circuit is the lamp on or off?

____

Answers

A. I_{B1}, along with a portion of V_S (0.7 volts if the transistor is silicon), turns Q_1 ON.

B. (1) I_{C1} flows; (2) V_{C1} drops to 0 V.

C. (1) base of Q_2 drops to 0 V; (2) Q_2 is OFF.

D. I_{C1} flows through Q_1 to ground.

E. Off.

20 Now, assume the switch is in the B position, as shown in Figure 4-10, and answer these questions.

Questions

A. How much base current I_{B1} flows into Q_1?________________

B. Is Q_1 ON or OFF?________________

C. What current flows through R_3?________________

D. Is Q_2 ON or OFF?________________

E. Is the lamp on or off?________________

Answers

A. None

B. OFF

C. I_{B2}

D. ON

E. On

21 Refer back to the circuit in Figure 4-9 and 4-10. Now, answer these questions assuming the supply voltage is 10 V.

Questions

A. Is the current through R_3 ever divided between Q_1 and Q_2? Explain.

____

____

B. What is the collector voltage of Q_2 with the switch in each position?

____

C. What is the collector voltage of Q_1 with the switch in each position?

____

Answers

A. No. If Q_1 is ON, all the current flows through it to ground as collector current. If Q_1 is OFF, all the current flows through the base of Q_2 as base current.

B. In position A, 10 volts because it is OFF.

Inposition B, 0 volts because it is ON.

C. In position A, 0 volts because it is ON.

In position B, the collector voltage of Q_1 equals the voltage drop across the forward-biased base-emitter junction of Q_2, because the base of Q_2 is in parallel with the collector of Q_1. The voltage drop across the forward-biased base-emitter junction will not rise to 10 V, but can only rise to 0.7 V if Q_2 is made of silicon.

22 Now calculate the values of R_1, R_2, and R_3 for this circuit. The process is similar to the one you used before, but you have to expand it to deal with the second transistor. Similar to the steps you used in problem 8. Follow these steps to calculate R_1, R_2, and R_3:

1. Determine the load current I_{C2}.
2. Determine β for Q_2. Call this β_2.
3. Calculate I_{B2} for Q_2. Use $I_{B2} = I_{C2}/\beta_2$.
4. Calculate R_3 to provide this base current. Use $R_3 = V_S/I_{B2}$.
5. R_3 is also the load for Q_1 when Q_1 is ON. Therefore, the collector current for Q_1 (I_{C1}) will have the same value as the base current for Q_2, as calculated in step 3.
6. Determine β_1, the β for Q_1.
7. Calculate the base current for Q_1. Use $I_{B1} = I_{C1}/\beta_1$.
8. Find R_1. Use $R_1 = V_s/I_{B1}$.
9. Choose R_2. For convenience, let $R_2 = R_1$.

Continue to work with the same circuit shown in Figure 4-11. Use the following values:

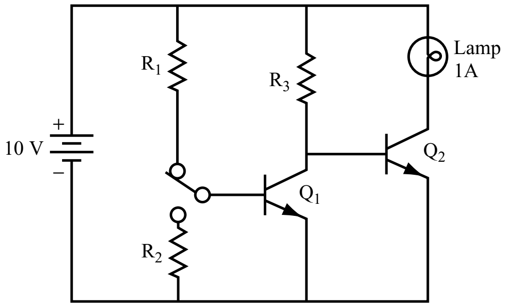

Figure 4-11

- A 10-volt lamp that draws 1 ampere; therefore $V_S = 10$ volts, $I_{C2} = 1$ A.
- $\beta_2 = 20$, $\beta_1 = 100$

Ignore any voltage drops across the transistors.

Questions

Calculate the following:

A. Find I_{B2} as in step 3.

I_{B2} = __________

B. Find R_3 as in step 4.

R_3 = __________

C. Calculate the load current for Q_1 when it is ON as shown in step 5.

I_{C1} = __________

D. Find the base current for Q_1.

I_{B1} = __________

E. Find R_1 as in step 8.

R_1 = __________

F. Choose a suitable value for R_2.

R_2 = __________

Answers

The following answers correspond to the steps.

A. **1.** I_{C2} is given as 1 A.

2. $\beta_2 = 20$ (given). This is a typical value for a transistor that would handle 1 A.

3. $I_{B2} = \frac{1\text{ A}}{20} = 50\text{ mA}$

B. **4.** $R_3 = \frac{10\text{ Volts}}{50\text{ mA}} = 200\ \Omega$

Note that the 0.7 V base-emitter drop has been ignored.

C. **5.** $I_{C1} = I_{B2} = 50$ mA

D. **6.** $\beta_1 = 100$

7. $I_{B1} = \frac{50\,\text{mA}}{100} = 0.5\,\text{mA}$

E. **8.** $R_1 = \frac{10\,\text{V}}{0.5\,\text{mA}} = 20\,\text{k}\Omega$

Again, the 0.7 V drop is ignored.

F. **9.** For convenience choose a value for R_2 that is the same as R_1, or 20 kΩ. This reduces the number of different components in the circuit. The fewer different components you have in a circuit, the less components you have to keep in your parts bin. You could, of course, choose any value between 1 kΩ and 1 MΩ.

23 Following the same procedure, and using the same circuit shown in Figure 4-11, work through this example. Assume that you are using a 28-volt lamp that draws 560 mA, and that $\beta_2 = 10$ and $\beta_1 = 100$.

Questions

Calculate the following:

A. I_{B2} = _______________

B. R_3 = _______________

C. I_{C1} = _______________

D. I_{B1} = _______________

E. R_1 = _______________

F. R_2 = _______________

Answers

A. 56 mA

B. 500 ohms

C. 56 mA

D. 0.56 mA

E. 50 kΩ

F. 50 kΩ by choice

The Three-Transistor Switch

24 The circuit shown in Figure 4-12 uses three transistors to switch a load on and off. In this circuit Q_1 is used to turn Q_2 ON and OFF, and Q_2 is used to turn Q_3 ON and OFF. The calculations are similar to those you performed in the last few problems, but a few additional steps are required to deal with the third transistor. Use this circuit diagram to determine the answers to the following questions.

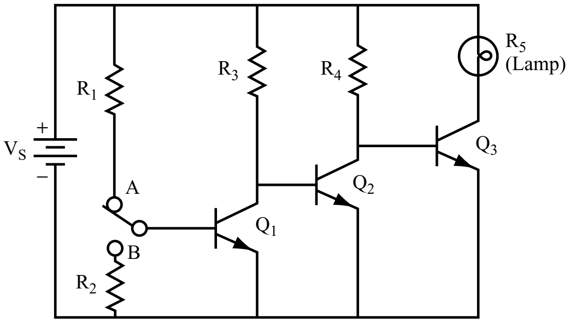

Figure 4-12

Questions

If the switch is in position A:

A. Is Q_1 ON or OFF?

B. Is Q_2 ON or OFF?

C. Where is current through R_4 flowing?

D. Is Q_3 ON or OFF?

Answers

A. ON

B. OFF

C. Into the base of Q_3

D. ON

25 Now use the same circuit as in problem 24.

Questions

If the switch is in position B:

A. Is Q_1 ON or OFF?

B. Is Q_2 ON or OFF?

C. Where is the current through R_4 flowing?

D. Is Q_3 ON or OFF?

E. Which switch position turns the lamp on?

F. How do the on/off positions for the switch in the three-transistor switch differ from the on/off positions for the switch in the two-transistor switch circuit?

Answers

A. OFF.

B. ON.

C. Through Q_2 to ground.

D. OFF.

E. Position A.

F. The positions are opposite. Therefore, if a circuit controls lamps with two transistors, and another circuit controls lamps with three transistors, flipping the switch that controls both circuits would change which lamps (or which other loads) are on.

26 Work through this example using the same equations you used for the two-transistor switch in problem 22. The steps are similar, but with a few added steps, as shown here:

1. Find the load current. This is often given.
2. Determine the current gain of Q_3. This is β_3 and usually it is a given value.
3. Calculate I_{B3}. Use $I_{B3} = I_{C3}/\beta_3$.
4. Calculate R_4. Use $R_4 = V_S/I_{B3}$.
5. Assume $I_{C2} = I_{B3}$.
6. Find β_2. Again this is a given value.
7. Calculate I_{B2}. Use $I_{B2} = I_{C2}/\beta_2$.
8. Calculate R_3. Use $R_3 = V_S/I_{B2}$.
9. Assume $I_{C1} = I_{B2}$.
10. Find β_1.
11. Calculate I_{B1}. Use $I_{B1} = I_{C1}/\beta_1$.
12. Calculate R_1. Use $R_1 = V_s/I_{B1}$.
13. Choose R_2.

For this example, use a 10-volt lamp that draws 10 amperes. Assume the βs of the transistors are given in the manufacturer's datasheets as $\beta_1 = 100$, $\beta_2 = 50$, and $\beta_3 = 20$. Now work through the steps, checking the answers for each step as you complete it.

Questions

Calculate the following:

A. I_{B3} = ____________

B. R_4 = ____________

C. I_{B2} = ____________

D. R_3 = ____________

E. I_{B1} = ____________

F. R_1 = ____________

G. R_2 = ____________

Answers

The answers here correspond to the steps.

A. **1.** The load current is given as 10 A.

2. β_3 is given as 20.

3. $I_{B3} = \frac{I_{C3}}{\beta_3} = \frac{10\text{ A}}{20} = 0.5\text{ A} = 500\text{ mA}$

B. **4.** $R_4 = \frac{10\text{ volts}}{500\text{ mA}} = 20\text{ ohms}$

C. **5.** $I_{C2} = I_{B3} = 500\text{ mA}$

6. β_2 is given as 50.

7. $I_{B2} = \frac{I_{C2}}{\beta_2} = \frac{500\text{ mA}}{50} = 10\text{ mA}$

D. **8.** $R_3 = \frac{10\text{ V}}{10\text{ mA}} = 1\text{ k}\Omega$

E. **9.** $I_{C1} = I_{B2} = 10\text{ mA}$

10. β_1 is given as 100.

11. $I_{B1} = \frac{I_{C1}}{\beta_1} = \frac{10\text{ mA}}{100} = 0.1\text{ mA}$

F. **12.** $R_1 = \frac{10\text{ V}}{0.1\text{ mA}} = 100\text{ k}\Omega$

G. **13.** R_2 can be chosen to be 100 kΩ also.

27 Determine the values in the same circuit for a 75-volt lamp that draws 6 A. Assume that $\beta_3 = 30$, $\beta_2 = 100$, and $\beta_1 = 120$.

Questions

Calculate the following values using the steps in problem 26:

A. I_{B3} = ________________

B. R_4 = ________________

C. I_{B2} = ________________

D. R_3 = ________________

E. I_{B1} = ________________

F. R_1 = ________________

G. R_2 = ________________

Answers

A. 200 mA

B. 375 Ω

C. 2 mA

D. 37.5 kΩ

E. 16.7 μA

F. 4.5 MΩ

G. Choose $R_2 = 1$ MΩ

Alternative Base Switching

28 In the examples of transistor switching, the actual switching was performed using a small mechanical switch placed in the base circuit of the first transistor. This switch has three terminals, and switches from position A to position B. (This is a single pole double throw switch.) This switch does not have a definite ON or OFF position as does a simple ON-OFF switch.

Question

Why couldn't a simple ON-OFF switch with only two terminals have been used with these examples?

____

Answer

An ON-OFF switch is either open or closed, and cannot switch between position A and position B, as shown earlier in Figure 4-12.

29 If you connect R_1, R_2, and a switch together as shown in Figure 4-13, you can use a simple ON-OFF switch with only two terminals. (This is a single pole single throw switch.)

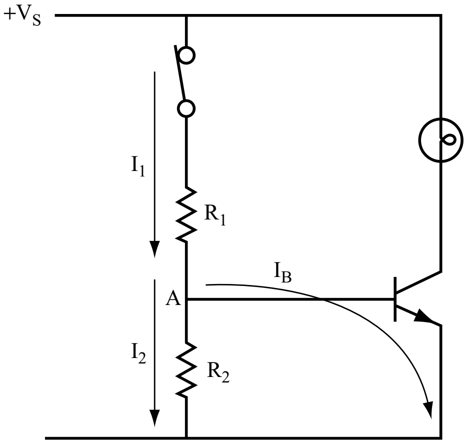

Figure 4-13

Questions

A. When the switch is open, is Q_1 ON or OFF?

____

B. When the switch is closed, is the lamp on or off?

____

Answers

A. OFF

B. On

30 When the switch is closed, current flows through R_1, However, at point A in Figure 4-13, the current divides into two paths. One path is the base current I_B, and the other is marked I_2.

Question

How could you calculate the total current I_1?

____

Answer

$I_1 = I_B + I_2$

31 The problem now is to choose the values of both R_1 and R_2 so that when the current divides, there will be sufficient base current to turn Q_1 ON.

Question

Consider this simple example. Assume the load is a 10-volt lamp that needs 100 mA of current, and $\beta = 100$. Calculate the base current required.

$I_B =$ ____________

Answer

$$I_B = \frac{100\,\text{mA}}{100} = 1\,\text{mA}$$

32 After the current I_1 flows through R_1, it must divide, and 1 mA of it becomes I_B. The remainder of the current is I_2. The difficulty at this point is that there is no unique value for either I_1 or I_2. In other words, you could assign them almost any value. The only restriction is that both must permit 1 mA of current to flow into the base of Q_1.

You must make an arbitrary choice for these two values. Based on practical experience, it is common to set I_2 to be 10 times greater than I_B. This split makes the circuits work reliably, and keeps the calculations easy:

$I_2 = 10\,I_B$

$I_1 = 11\,I_B$

Question

In problem 31 you determined that $I_B = 1$ mA. What is the value of I_2?

____

Answer

$I_2 = 10$ mA

33 Now it is possible to calculate the value of R_2. The voltage across R_2 is the same as the voltage drop across the base-emitter junction of Q_1. Assume that the circuit uses a silicon transistor, so this voltage is 0.7 V.

Questions

A. What is the value of R_2?

B. What is the value R_1?

Answers

A. $R_2 = \dfrac{0.7\,\text{V}}{10\,\text{mA}} = 70\,\text{ohms}$

B. $R_2 = \dfrac{(10\,\text{V} - 0.7\,\text{V})}{11\,\text{mA}} = \dfrac{9.3\,\text{V}}{11\,\text{mA}} = 800\,\text{ohms (approximately)}$

You can ignore the 0.7 V in this case, which would give $R_1 = 910$ ohms.

34 The resistor values you calculated in problem 33 ensure that the transistor turns ON, and that the 100 mA current (I_C) you need to illuminate the lamp flows through the lamp and the transistor. The labeled circuit is shown in Figure 4-14.

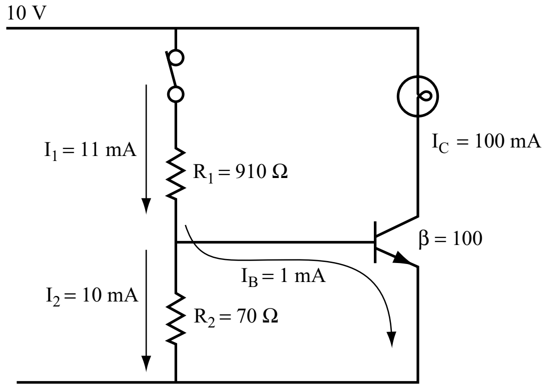

Figure 4-14

Questions

For each of the following lamps, perform the same calculations you used in the last few problems to find the values of R_1 and R_2.

A. A 28-volt lamp that draws 56 mA. $\beta = 100$

____

B. A 12-volt lamp that draws 140 mA. $\beta = 50$

____

Answers

A. $I_B = \dfrac{56\,\text{mA}}{100} = 0.56\,\text{mA}$

$I_2 = 5.6\,\text{mA}$

$R_2 = \dfrac{0.7\,\text{V}}{5.6\,\text{mA}} = 125\,\text{ohms}$

$R_1 = \dfrac{28\,\text{V}}{6.16\,\text{mA}} = 4.5\,\text{k}\Omega$

B. $R_2 = 25\,\text{ohms}$

$R_1 = 400\,\text{ohms}$

35 The arbitrary decision to make the value of I_2 10 times the value of I_B is obviously subject to considerable discussion, doubt, and disagreement. *Transistors are not exact devices*; *they are not carbon copies of each other*. In general, any transistor of the same type will have a different β from any other because of the variance in tolerances found in component manufacturing. This leads to a degree of inexactness in designing and analyzing transistor circuits. The truth is that if you follow exact mathematical procedures, it will complicate your life. In practice, a few ‘‘rules of thumb’’ have been developed to help you make the necessary assumptions. These rules lead to simple equations that provide workable values for components that you can use in designing circuits.

The choice of $I_2 = 10I_B$ is one such rule of thumb. Is it the only choice that will work? Of course not. Almost any value of I_2 that is at least 5 times larger than I_B will work. Choosing 10 times the value is a good option for three reasons:

- It is a good practical choice. It will always work.
- It makes the arithmetic easy.
- It's not overly complicated, and doesn't involve unnecessary calculations.

Question

In the example from problem 32, $I_B = 1$ mA and $I_2 = 10$ mA. Which of the following values could also work efficiently for I_2?

A. 5 mA

B. 8 mA

C. 175 mA

D. 6.738 mA

E. 1 mA

Answer

Choices A, B, and D. Value C is much too high to be a sensible choice, and E is too low.

36 Before you continue with this chapter, answer the following review questions.

Questions

A. Which switches faster, the transistor or the mechanical switch?

____

B. Which can be more accurately controlled?

____

C. Which is the easiest to operate remotely?

____

D. Which is the most reliable?

____

E. Which has the longest life?

____

Answers

A. The transistor is much faster.

B. The transistor.

C. The transistor.

D. The transistor.

E. Because transistors have no moving parts they have a much longer operating lifetime than a mechanical switch. A mechanical switch will fail after several thousand operations, while transistors can be operated several million times a second and last for years.

Switching The JFET

37 The use of the junction field effect transistor (JFET) as a switch is discussed in the next few problems. You may want to review problems 29 through 32 of Chapter 3 where this book introduced the JFET.

The JFET is considered a ''normally on'' device, which means that with 0 volts applied to the input terminal (called the *gate*), it is ON and current can flow through the transistor. When you apply a voltage to the gate, the device conducts less current because the resistance of the drain to source channel increases. At some point, as the voltage increases, the value of the resistance in the channel becomes so high that the device ''cuts off'' the flow of current.

Questions

A. What are the three terminals for a JFET called, and which one controls the operation of the device?

____

B. What turns the JFET ON and OFF?

____

Answers

A. Drain, source, and gate, with the gate acting as the control.

B. When the gate voltage is zero (at the same potential as the source), the JFET is ON. When the gate to source voltage difference is high, the JFET is OFF.

The JFET Experiment

38 The objective of the following experiment is to determine the drain current that will flow when a JFET is fully ON and the gate voltage needed to fully shut the JFET OFF, using the circuit shown in Figure 4-15. You can change the gate voltage (actually, the voltage difference between the gate and the source, or V_{GS}) by adjusting the potentiometer, while measuring the resulting current flow through the transistor from drain to source (I_D). When the JFET is OFF, I_D is at zero; when the JFET is fully ON, I_D is at its maximum (called I_{DSS}).

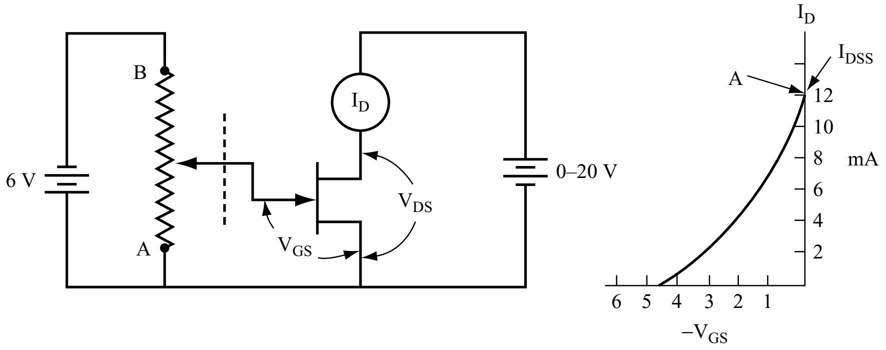

Figure 4-15

You will need the following equipment and supplies:

- One 6 V battery pack.
- One 12 V battery pack (or a lab power supply).
- One multimeter set to measure current.
- One multimeter set to measure voltage.
- One JFET.
- One potentiometer. Any value of potentiometer will work. If you have a selection available, use a 10 kΩ potentiometer.
- One breadboard.

If you do not have what you need to set up the circuit and measure the values, just read through the experiment.

Follow these steps to complete the experiment:

1. Set up the circuit shown in Figure 4-15 on the breadboard with the power supply for the drain portion of the circuit set to 12 V.

2. Set the potentiometer to 0 ohms and take a reading of V_{GS} and I_D and record the readings in the following table.

V_{GS}	I_D

3. Increase the potentiometer resistance and take another set of readings and record them. Repeat this until I_D drops to 0 mA.
4. 4 Plot the recorded points on a graph as shown on the right-hand side of Figure 4-15, with I_D as the vertical axis and V_{GS} as the horizontal axis. Draw a curve through the points.

With the potentiometer set at point A (0 ohms), the voltage from the gate to the source is zero ($V_{GS} = 0$). The current that flows between the drain and source terminals of the JFET at this time is at its maximum value, and is called the *saturation current* (I_{DSS}).

On the graph shown in the right side of Figure 4-15, the saturation point is indicated at A. This graph shows the transfer curve, and is a characteristic curve that is included on JFET datasheets.

NOTE **If you are using a lab power supply for the drain portion of the circuit, you should have it set to 12 volts. One property of the saturation current is that when V_{GS} is set at zero, and the transistor is fully ON, the current doesn't drop as long as the value of V_{DS} is above a few volts. If you have an adjustable power supply, you can determine the value of V_{DS} at which I_D starts to drop by starting with the power supply set at 12 volts. Watch the value of I_D as you lower the power supply voltage until you see I_D start to decrease.**

Questions

Using the transfer curve shown, answer the following:

A. With $V_{GS} = 0$, what is the value of drain current?

B. Why is this value called the drain saturation current?

C. What is the gate to source cutoff voltage for the curve shown?

D. Why is this called a cutoff voltage?

Answers

A. 12 mA on the graph.

B. The word saturation is used to indicate that the current is at its maximum.

C. Approximately −4.2 V on the graph.

D. It is termed a cutoff voltage because at this value the drain current goes to 0 A.

39 Now, look at the circuit shown in Figure 4-16. Assume that the JFET has the transfer characteristic shown by the curve in Figure 4-15.

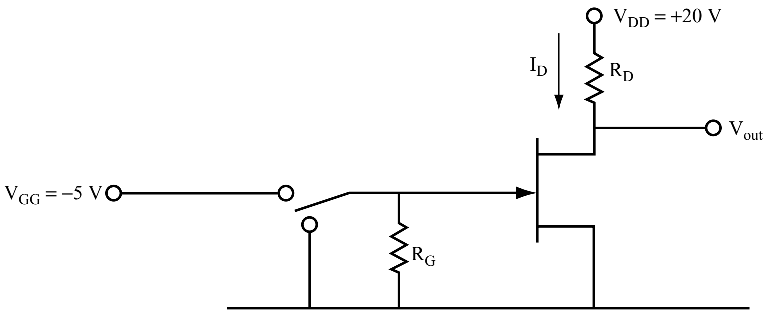

Figure 4-16

When the gate is connected to ground, the drain current will be at 12 mA. Assuming that the drain to source resistance is negligible, you can calculate the required value for R_D using the following formula:

$$R_D = \frac{V_{DD}}{I_{DSS}}$$

If you know the drain to source voltage, then you can include it in the calculation.

$$R_D = \frac{(V_{DD} - V_{DS})}{I_{DSS}}$$

Question

What should the value of R_D be for the I_{DSS} shown at Point A in the curve?

Answer

$$R_D = \frac{20\,\text{V}}{12\,\text{mA}} = 1.67\,\text{k}\Omega$$

40 For the JFET circuit shown in Figure 4-16, assume that $V_{DS} = 1$ V when the I_D is at saturation.

Questions

A. What is the required value of R_D?

B. What is the effective drain to source resistance (r_{DS}) in this situation?

Answers

A. $R_D = \dfrac{(20\,\text{volts} - 1\,\text{volt})}{12\,\text{mA}} = 1583\,\text{ohms}$

B. $r_{DS} = \dfrac{V_{DS}}{I_{DSS}} = \dfrac{1\,\text{volt}}{12\,\text{mA}} = 83\,\text{ohms}$

NOTE **You can see from this calculation that R_D is 19 times greater than r_{DS}. Thus, ignoring V_{DS} and assuming that $r_{DS} = 0$ does not greatly affect the value of R_D. The 1.67 kΩ value is only about 5 percent higher than the 1583 ohm value for R_D.**

41 Now, turn the JFET OFF. From the curve shown in Figure 4-15, you can see that a cutoff value of −4.2 V is required. Use a gate to source value of −5 V to ensure that the JFET is in the ''hard OFF'' state. The purpose of resistor R_G is to ensure that the gate is connected to ground while you flip the switch between terminals, changing the gate voltage from one level to the other. Use a large value of 1 MΩ here to avoid drawing any appreciable current from the gate supply.

Question

When the gate is at the −5 V potential, what is the drain current and the resultant output voltage?

Answer

$I_D = 0$ A and $V_{out} = V_{DS} = 20$ V, which is V_{DD}

Summary

In this chapter, you learned about the transistor switch and how to calculate the resistor values required to use it in a circuit.

- You worked with a lamp as the load example, because this provides an easy visual demonstration of the switching action. All of the circuits shown in this chapter will work when you build them on a breadboard, and the voltage and current measurements will be very close to those in the text.
- You have not yet learned all there is to transistor switching. For example, you haven't found out how much current a transistor can conduct before it burns out, what maximum voltage a transistor can sustain, or how fast a transistor can switch ON and OFF. You can learn these things from the datasheet for each transistor model, so these are not covered here.
- When you use the JFET as a switch, it will not switch as fast as a BJT, but it does have certain advantages relating to its large input resistance. The JFET does not draw any current from the control circuit in order to operate. Conversely, a BJT will draw current from the control circuit because of its lower input resistance.

Self-Test

These questions test your understanding of the concepts introduced in this chapter. Use a separate sheet of paper for your diagrams or calculations. Compare your answers with the answers provided.

For the first three questions, use the circuit shown in Figure 4-17. The objective is to find the value of R_B that will turn the transistor ON. As you may know, resistors are manufactured with ''standard values.'' After you have calculated an exact value, choose the nearest standard resistor value from Appendix D.

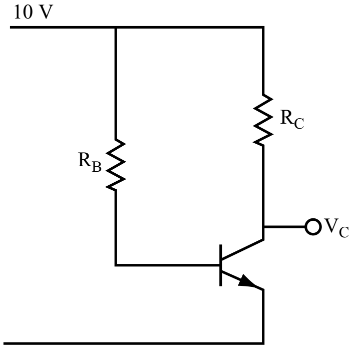

Figure 4-17

1. $R_C = 1\Omega$, $\beta = 100$, $R_B =$ ____________
2. $R_C = 4.7\ k\Omega$, $\beta = 50$. $R_B =$ ____________
3. $R_C = 22\ k\Omega$, $\beta = 75$. $R_B =$ ____________

For questions 4–6, use the circuit shown in Figure 4-18. Find the values of R_3, R_2, and R_1 that ensure that Q_2 is ON or OFF when the switch is in the corresponding position. Calculate the resistors in the order given. After you have found the exact values, again choose the nearest standard resistor values.

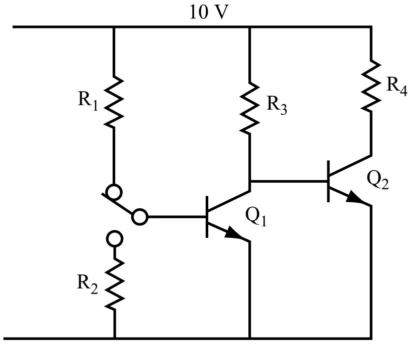

Figure 4-18

NOTE You should be aware that rounding off throughout a problem, or rounding off the final answer, could produce slightly different results.

4. $R_4 = 100$ ohms, $\beta_1 = 100$, $\beta_2 = 20$.

$R_3 =$ ___________ $R_1 =$ ___________ $R_2 =$ ___________

5. $R_4 = 10$ ohms, $\beta_1 = 50$, $\beta_2 = 20$.

$R_3 =$ ___________ $R_1 =$ ___________ $R_2 =$ ___________

6. $R_4 = 250$ ohms, $\beta_1 = 75$, $\beta_2 = 75$.

$R_3 =$ ___________ $R_1 =$ ___________ $R_2 =$ ___________

For questions 7–9, find the values of the resistors in the circuit shown in Figure 4-19 that ensure that Q_3 will be ON or OFF when the switch is in the corresponding position. Then, select the nearest standard resistor values.

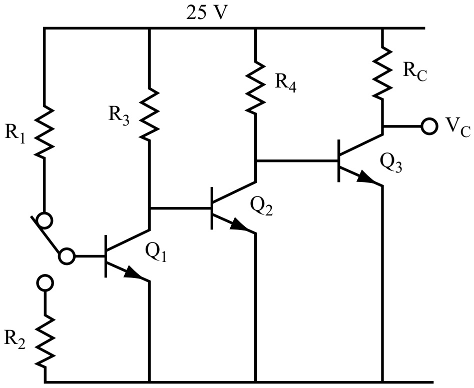

Figure 4-19

7. $R_C = 10$ ohms, $\beta_3 = 20$, $\beta_2 = 50$, $\beta_1 = 100$.

$R_4 =$ ___________ $R_2 =$ ___________

$R_3 =$ ___________ $R_1 =$ ___________

8. $R_C = 28$ ohms, $\beta_3 = 10$, $\beta_2 = 75$, $\beta_1 = 75$.

$R_4 =$ ___________ $R_2 =$ ___________

$R_3 =$ ___________ $R_1 =$ ___________

9. $R_C = 1$ ohm, $\beta_3 = 10$, $\beta_2 = 50$, $\beta_1 = 75$.

$R_4 =$ ___________ $R_2 =$ ___________

$R_3 =$ ___________ $R_1 =$ ___________

Questions 10–12 use the circuit shown in Figure 4-20. Find values for R_1 and R_2 that ensure that the transistor turns ON when the switch is closed and OFF when the switch is open.

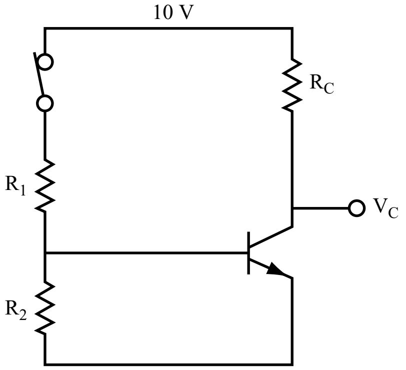

Figure 4-20

10. $R_C = 1\ k\Omega$, $\beta = 100$.

R_1 = ____________ R_2 = ____________

11. $R_C = 22\ k\Omega$, $\beta = 75$.

R_1 = ____________ R_2 = ____________

12. $R_C = 100\ \Omega$, $\beta = 30$.

R_1 = ____________ R_2 = ____________

13. An N-channel JFET has a transfer curve with the following characteristics. When $V_{GS} = 0$ V, the saturation current, (I_{DSS}) is 10.5 mA; the cutoff voltage is −3.8 V. With a drain supply of 20 V, design a biasing circuit that switches the JFET from the ON state to the OFF state.

Answers to Self-Test

The exercises in this Self-Test show calculations that are typical of those found in practice, and the odd results you sometimes get are quite common. Thus, choosing a nearest standard value of resistor is a common practice. If your answers do not agree with those given here, review the problems indicated in parentheses before you go on to the next chapter.

1.	100 kΩ	(problem 8)
2.	235 kΩ. Choose 240 kΩ as a standard value.	(problem 8)
3.	1.65 MΩ. Choose 1.6 MΩ as a standard value.	(problem 8)
4.	$R_3 = 2k\Omega$; $R_1 = 200\ k\Omega$; $R_2 = 200\ k\Omega$. Use these values.	(problem 22)

5.	$R_3 = 200$ ohms; $R_1 = 10$ kΩ; $R_2 = 10$ kΩ. Use these values.	(problem 22)
6.	$R_3 = 18.8$ kΩ. Choose 18 kΩ as a standard value.	(problem 22)
	$R_1 = 1.41$ MΩ. Choose 1.5 MΩ as a standard value.	
	Select 1 MΩ for R_2.	
7.	$R_4 = 200$ ohms; $R_3 = 10$ kΩ; $R_2 = 1$ MΩ; $R_1 = 1$ MΩ. Use these values.	(problem 26)
8.	$R_4 = 280$ ohms. Choose 270 ohms as a standard value.	(problem 26)
	$R_3 = 21$ kΩ. Choose 22 kΩ as a standard value.	
	$R_2 = 1.56$ MΩ. Choose 1.5 or 1.6 MΩ as a standard value.	
	$R_1 = 1.56$ MΩ. Choose 1.5 or 1.6 MΩ as a standard value.	
9.	$R_4 = 10$ ohms. Choose 10 ohms as a standard value.	(problem 26)
	$R_3 = 500$ ohms. Choose 510 ohms as a standard value.	
	$R_2 = 37.5$ kΩ. Choose 39 kΩ as a standard value.	
	$R_1 = 37.5$ kΩ. Choose 39 kΩ as a standard value.	
10.	$R_2 = 700$ ohms. Choose 680 or 720 ohms as a standard value.	(problems 31–33)
	$R_1 = 8.45$ kΩ. Choose 8.2 kΩ as a standard value.	
	If 0.7 is ignored, then $R_1 = 9.1$ kΩ.	
11.	$R_2 = 11.7$ kΩ. Choose 12 KΩ as a standard value.	(problems 31–33)
	$R_1 = 141$ kΩ. Choose 140 or 150 kΩ as a standard value.	
12.	$R_2 = 21$ ohms. Choose 22 ohms as a standard value.	(problems 31–33)
	$R_1 = 273$ ohms. Choose 270 ohms as a standard value.	
13.	Use the circuit shown in Figure 4-16. Set the gate supply at a value slightly more negative than −3.8 V. A value of −4 V would work. Make resistor $R_G = 1$ MΩ. Set R_D at a value of (20 volts)/(10.5 mA), which calculates a resistance of 1.9 kΩ. You can wire a standard resistor of 1 kΩ in series with a standard resistor of 910 ohms to obtain a resistance of 1.91 kΩ.	(problems 39 and 41)

CHAPTER

5

AC Pre-Test and Review

You need to have some basic knowledge of alternating current (AC) to study electronics. To understand AC, you basically have to understand sine waves.

A *sine wave* is simply a shape, like waves in the ocean. Sine waves in electronics are used to represent voltage or current moving up and down in magnitude. In AC electronics, some signals or power sources (such as the house current provided at a wall plug) are represented by sine waves. The sine wave shows how the voltage moves from 0 volts to its peak voltage, and back down through 0, its negative peak voltage at 60 cycles per second, or 60 Hertz (Hz).

The sound from a musical instrument also consists of sine waves. When you combine sounds (such as all the instruments in an orchestra), you get complex combinations of many sine waves, at various frequencies.

The study of AC starts with the properties of simple sine waves, and continues with an examination of how electronic circuits can generate or change sine waves.

This chapter discusses the following:

- The generator
- The sine wave
- Peak-to-peak and RMS voltages
- Resistors in AC circuits
- Capacitive and inductive reactance
- Resonance

The Generator

1 In electronic circuits powered by direct current, the voltage source is usually a battery or solar cell, which produces a constant voltage and a constant current through a conductor.

In electronic circuits or devices powered by alternating current, the voltage source is usually a *generator*, which produces a regular output waveform, such as a sine wave.

Question

Draw one cycle of a sine wave.

Answer

See Figure 5-1.

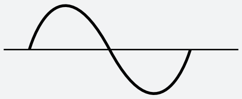

Figure 5-1

2 A number of electronic instruments are used in the laboratory to produce sine waves. For purposes of this discussion, the term *generator* means a sine wave source. These generators allow you to adjust the voltage and frequency by turning a dial or pushing a button. These instruments are called by various names, generally based on their method of producing the sine wave, or their application as a test instrument. The most popular generator at present is called a *function generator*. It actually provides a choice of functions or waveforms, including a square wave and a triangle wave. These waveforms are useful in testing certain electronic circuits.

The symbol shown in Figure 5-2 represents a generator. Note that a sine wave shown within a circle designates an AC sine wave source.

Figure 5-2

Questions

A. What is the most popular instrument used in the lab to produce waveforms?

B. What does the term AC mean?

____

C. What does the sine wave inside a generator symbol indicate?

____

Answers

A. The function generator.

B. Alternating current, as opposed to direct current.

C. The generator is a sine wave source.

3 Some key parameters of sine waves are indicated in Figure 5-3. The two axes are voltage and time.

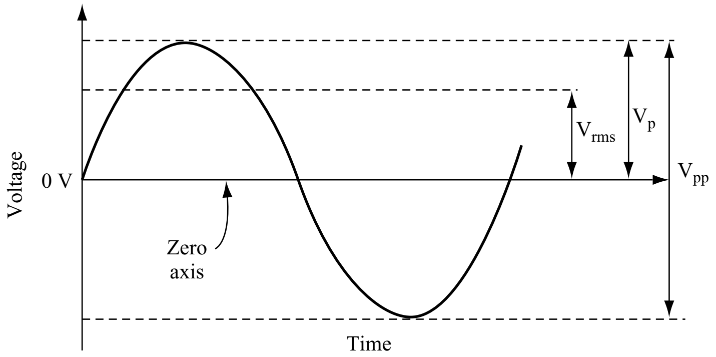

Figure 5-3

The *zero axis* is the reference point from which all voltage measurements are made.

Questions

A. What is the purpose of the zero axis?

____

B. What is the usual point for making time measurements?

____

Answers

A. It is the reference point from which all voltage measurements are made.

B. Time measurements can be made from any point in the sine wave, but usually they are made from a point at which the sine wave crosses the zero axis.

4 The three most important voltage or amplitude measurements are the *peak* (p), *peak-to-peak* (pp), and the *root mean square* (rms) voltages.

The following equations show the relationship between p, pp, and rms voltages for sine waves. The relationships between p, pp, and rms voltages differ for other waveforms (such as square waves).

$$V_p = \sqrt{2} \times V_{rms}$$

$$V_{pp} = 2V_p = 2 \times \sqrt{2} \times V_{rms}$$

$$V_{rms} = \frac{1}{\sqrt{2}} \times V_p = \frac{1}{\sqrt{2}} \times \frac{V_{pp}}{2}$$

Note the following:

$$\sqrt{2} = 1.414$$

$$\frac{1}{\sqrt{2}} = 0.707$$

Question

If the pp voltage of a sine wave is 10 volts, find the rms voltage.

Answer

$$V_{rms} = \frac{1}{\sqrt{2}} \times \frac{V_{pp}}{2} = 0.707 \times \frac{10}{2} = 3.535\,\text{V}$$

5 Calculate the following for a sine wave.

Question

If the rms voltage is 2 volts, find the pp voltage.

Answer

$$V_{pp} = 2 \times \sqrt{2} \times V_{rms} = 2 \times 1.414 \times 2 = 5.656\,\text{V}$$

6 Calculate the following for a sine wave.

Questions

A. $V_{pp} = 220$ volts. Find V_{rms}.

B. $V_{rms} = 120$ volts. Find V_{pp}.

Answers

A. 77.77 volts

B. 340 volts (This is the common house current supply voltage; 340 $V_{pp} = 120$ V_{rms}.)

7 There is a primary time measurement for sine waves. The duration of the complete sine wave is shown in Figure 5-4 and referred to as a *cycle*. All other time measurements are fractions or multiples of a cycle.

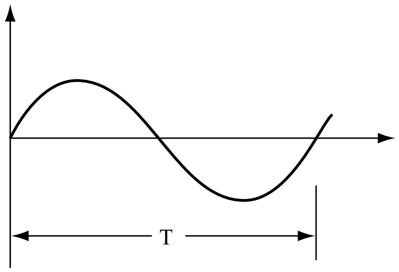

Figure 5-4

Questions

A. What is one complete sine wave called?

B. What do you call the time it takes to complete one sine wave?

C. How is the frequency of a sine wave related to this time?

D. What is the unit for frequency?

E. If the period of a sine wave is 0.5 ms, what is its frequency? What is the frequency of a sine wave with a period of 40 μsec?

F. If the frequency of a sine wave is 60 Hz, what is its period? What is the period of sine waves with frequencies of 12.5 kHz and 1 MHz?

Answers

A. A cycle

B. The period, T

C. $f = 1/T$

D. Hertz (Hz) is the standard unit for frequency. One Hertz equals one cycle per second.

E. 2 kHz, 25 kHz

F. 16.7 ms, 80 μsec, 1 μsec

8 Choose all answers that apply.

Question

Which of the following could represent electrical AC signals?

A. A simple sine wave

B. A mixture of many sine waves, of different frequencies and amplitudes

C. A straight line

Answers

A and B

Resistors in AC Circuits

9 Alternating current is passed through components, just as direct current is. Resistors interact with alternating current just as they do with direct current.

Question

Suppose an AC signal of 10 V_{pp} is connected across a 10 ohm resistor. What is the current through the resistor?

Answer

Use Ohm's law.

$$I = \frac{V}{R} = \frac{10\,V_{pp}}{10\,\text{ohms}} = 1\,A_{pp}$$

Because the voltage is given in pp, the current is a pp current.

10 An AC signal of 10 V_{rms} is connected across a 20 ohm resistor.

Question

Find the current.

Answer

$$I = \frac{10\,V_{rms}}{20\,\text{ohms}} = 0.5\,A_{rms}$$

Because the voltage was given in rms, the current is rms.

11 You apply an AC signal of 10 V_{pp} to the voltage divider circuit shown in Figure 5-5.

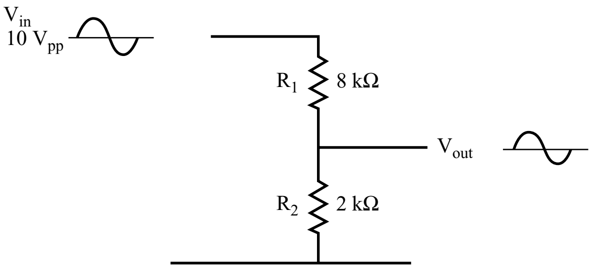

Figure 5-5

Question

Find V_{out}.

Answer

$$V_{out} = V_{in} \times \frac{R_2}{(R_1 + R_2)} = 10 \times \frac{2k\Omega}{(8k\Omega + 2k\Omega)} = 10 \times \frac{2}{10} = 2V_{pp}$$

Capacitors in AC Circuits

12 A capacitor opposes the flow of an AC current.

Questions

A. What is this opposition to the current flow called?

B. What is this similar to in DC circuits?

Answers

A. Reactance

B. Resistance

13 Just as with resistance, you determine reactance by using an equation.

Questions

A. What is the equation for reactance?

B. What does each symbol in the equation stand for?

C. How does the reactance of a capacitor change as the frequency of a signal increases?

Answers

A. $X_C = \dfrac{1}{2\pi fC}$

B. X_C = the reactance of the capacitor in ohms

f = the frequency of the signal in hertz.

C = the value of the capacitor in farads.

C. The reactance of a capacitor decreases as the frequency of the signal increases.

14 Assume the capacitance is 1 μF and the frequency is 1 kHz.

Question

Find the capacitor's reactance. (*Note*: $1/(2\pi) = 0.159$, approximately.)

Answer

$$X_C = \frac{1}{2\pi fC}$$

f = 1 kHz = 10^3 Hz

C = 1 μF = 10-6 F

Thus,

$$X_C = \frac{0.159}{10^3 \times 10^{-6}} = 160\,\text{ohms}$$

15 Now, perform these two simple calculations. In each case, find X_{C1}; the capacitor's reactance at 1 kHz, and X_{C2}; the capacitors reactance at the frequency specified in the question.

Questions

Find X_{C1} and X_{C2}:

A. C = 0.1 μF, f = 100 Hz.__________

B. C = 100 μF, f = 2 kHz.__________

Answers

A. At 1 kHz, $X_{C1} = 1600$ ohms; at 100 Hz, $X_{C2} = 16{,}000$ ohms

B. At 1 kHz, $X_{C1} = 1.6$ ohms; at 2 kHz, $X_{C2} = 0.8$ ohms

A circuit containing a capacitor in series with a resistor (as shown in Figure 5-6) functions as a voltage divider.

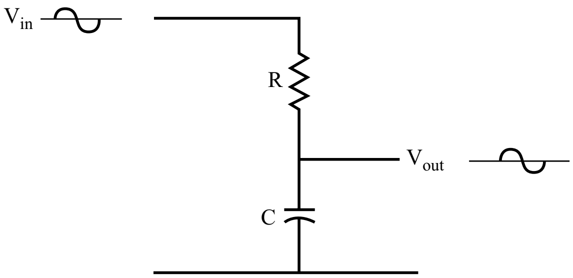

Figure 5-6

While this voltage divider provides a reduced output voltage, just like a voltage divider using two resistors, there's a complication. If you view the output and input voltage waveforms on an oscilloscope, you see that one is shifted away from the other. The two waveforms are said to be ''out of phase.'' *Phase* is an important concept in understanding how certain electronic circuits work. In Chapter 6, you learn about phase relationships for some AC circuits. You will also encounter this again when you study amplifiers.

The Inductor in an AC Circuit

16 An *inductor* is a coil of wire, usually wound many times around a piece of soft iron. In some cases, the wire is wound around a nonconducting material.

Questions

A. Is the AC reactance of an inductor high or low? Why?

____

B. Is the DC resistance high or low?

____

C. What is the relationship between the AC reactance and the DC resistance?

____

D. What is the formula for the reactance of an inductor?

____

Answers

A. Its AC reactance (X_L), which can be quite high, is a result of the electromagnetic field that surrounds the coil and induces a current in the opposite direction to the original current.

B. Its DC resistance (r), which is usually quite low, is simply the resistance of the wire that makes up the coil.

C. None.

D. $X_L = 2\pi fL$, where L = the value of the inductance in henrys. Using this equation, you can expect the reactance of an inductor to increase as the frequency of a signal passing through it increases.

17 Assume the inductance value is 10 henrys (H) and the frequency is 100 Hz.

Question

Find the reactance.

____

Answer

$X_L = 2\pi fL = 2\pi \times 100 \times 10 = 6280$ ohms

18 Now, try these two examples. In each case, find X_{L1}; the reactance of the inductor at 1 kHz and X_{L2}; the reactance at the frequency given in the question.

Questions

A. L = 1 mH (0.001 H), f = 10 kHz

____

B. L = 0.01 mH, f = 5 MHz

Answers

A. $X_{L1} = 6.28 \times 10^3 \times 0.001 = 6.28$ ohms

$X_{L2} = 6.28 \times 10 \times 10^3 \times 0.001 = 62.8$ ohms

B. $X_{L1} = 6.28 \times 10^3 \times 0.01 \times 10^{-3} = 0.0628$ ohms

$X_{L2} = 6.28 \times 5 \times 10^6 \times 0.01 \times 10^{-3} = 314$ ohms

A circuit containing an inductor in series with a resistor functions as a voltage divider, just as a circuit containing a capacitor in series with a resistor does. Again, the relationship between the input and output voltages is not as simple as a resistive divider. The circuit is discussed in Chapter 6.

Resonance

19 Calculations in previous problems demonstrate that capacitive reactance decreases as frequency increases, and that inductive reactance increases as frequency increases. If a capacitor and an inductor are connected in series, there will be one frequency at which their reactance values are equal.

Questions

A. What is this frequency called?

B. What is the formula for calculating this frequency? You can find it by setting $X_L = X_C$ and solving for frequency.

Answers

A. The resonant frequency

B. $2\pi fL = 1/(2\pi fC)$. Rearranging the terms in this equation to solve for f yields the following formula for the resonant frequency (f_r):

$$f_r = \frac{1}{2\pi\sqrt{LC}}$$

20 If a capacitor and an inductor are connected in parallel, there will also be a resonant frequency. Analysis of a parallel resonant circuit is not as simple as for a series resonant circuit. The reason for this is that inductors always have some internal resistance, which complicates some of the equations. However, under certain conditions, the analysis is similar. For example, if the reactance of the inductor in ohms is more than 10 times greater than its own internal resistance (r), the formula for the resonant frequency is the same as if the inductor and capacitor were connected in series. This is an approximation that you will use often.

Questions

For the following inductors, determine if the reactance is more or less than 10 times its internal resistance. A resonant frequency is provided.

A. $f_r = 25$ kHz, $L = 2$ mH, $r = 20$ ohms

B. $f_r = 1$ kHz, $L = 33.5$ mH, $r = 30$ ohms

Answers

A. $X_L = 314$ ohms, which is more than 10 times greater than r.

B. $X_L = 210$ ohms, which is less than 10 times greater than r.

NOTE **Chapter 7 discusses both series and parallel resonant circuits. At that time, you'll learn many useful techniques and formulas.**

21 Find the resonant frequency (f_r) for the following capacitors and inductors when they are connected both in parallel and in series. Assume r is negligible.

Questions

Determine f_r:

A. $C = 1$ μF, $L = 1$ henry

B. $C = 0.2$ μF, $L = 3.3$ mH

Answers

A. $f_r = \dfrac{0.159}{\sqrt{10^{-6} \times 1}} = 160\,\text{Hz}$

B. $f_r = \dfrac{0.159}{\sqrt{3.3 \times 10^{-3} \times 0.2 \times 10^{-6}}} = 6.2\,\text{kHz}$

22 Now, try these two final examples.

Questions

Determine f_r:

A. C = 10 μF, L = 1 henry

____

B. C = 0.0033 μF, L = 0.5 mH

____

Answers

A. f_r = 50 Hz (approximately)

B. f_r = 124 kHz

Understanding resonance is important to understanding certain electronic circuits, such as filters and oscillators.

Filters are electronic circuits that either block a certain band of frequencies, or pass a certain band of frequencies. One common use of filters is in circuits used for radio, TV, and other communications applications. *Oscillators* are electronic circuits that generate a continuous output without an input signal. The type of oscillator that uses a resonant circuit produces pure sine waves. (You learn more about oscillators in Chapter 9.)

Summary

Following are the concepts presented in this chapter:

- The sine wave is used extensively in AC circuits.
- The most common laboratory generator is the function generator.
- $V_p = \sqrt{2} \times V_{rms}$, $V_{pp} = 2\sqrt{2} \times V_{rms}$

- $f = 1/T$
- $I_{pp} = \frac{V_{pp}}{R}, \; I_{rms} = \frac{V_{rms}}{R}$
- Capacitive reactance is calculated as follows:

  $$X_C = \frac{1}{(2\pi fC)}$$

- Inductive reactance is calculated as follows:

  $$X_L = 2\pi fL$$

- Resonant frequency is calculated as follows:

  $$f_r = \frac{1}{2\pi\sqrt{LC}}$$

Self-Test

The following problems test your understanding of the basic concepts presented in this chapter. Use a separate sheet of paper for calculations if necessary. Compare your answers with the answers provided following the test.

1. Convert the following peak or peak-to-peak values to rms values:

A. $V_p = 12$ V, $V_{rms} =$ ____________________

B. $V_p = 80$ mV, $V_{rms} =$ ____________________

C. $V_{pp} = 100$ V, $V_{rms} =$ ____________________

2. Convert the following rms values to the required values shown:

A. $V_{rms} = 120$ V, $V_p =$ ____________________

B. $V_{rms} = 100$ mV, $V_p =$ ____________________

C. $V_{rms} = 12$ V, $V_{pp} =$ ____________________

3. For the given value, find the period or frequency:

A. $T = 16.7$ ms, $f =$ ____________________

B. $f = 15$ kHz, $T =$ ____________________

4. For the circuit shown in Figure 5-7, find the total current flow and the voltage across R_2, (V_{out}).

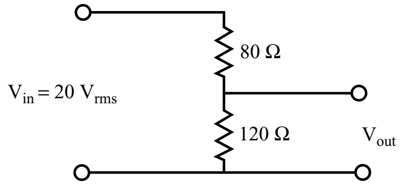

Figure 5-7

5. Find the reactance of the following components:

A. $C = 0.16\ \mu F$, $f = 12\ kHz$, $X_C =$ ____________________

B. $L = 5\ mH$, $f = 30\ kHz$, $X_L =$ ____________________

6. Find the frequency necessary to cause each reactance shown:

A. $C = 1\ \mu F$, $X_C = 200$ ohms, $f =$ ____________________

B. $L = 50\ \mu F$, $X_L = 320$ ohms, $f =$ ____________________

7. What would be the resonant frequency for the capacitor and inductor values given in A and B of question 5 if they were connected in series?

____

8. What would be the resonant frequency for the capacitor and inductor values given in A and B of question 6 if they were connected in parallel? What assumption would you have to make?

____

Answers to Self-Test

If your answers do not agree with those provided here, review the problems indicated in parentheses before you go on to the next chapter.

1.	A.	$8.5\ V_{rms}$	(problems 4–6)
	B.	$56.6\ V_{rms}$	
	C.	$35.4\ V_{rms}$	
2.	A.	$169.7\ V_p$	(problems 4–6)
	B.	$141.4\ mV_p$	
	C.	$33.9\ V_{pp}$	
3.	A.	60 Hz	(problem 7)
	B.	66.7 µsec	
4.	$I_T = 0.1\ A_{rms}$, $V_{out} = 12\ V_{rms}$		(problems 9–11)

5.	A.	82.9 ohms	(problems 14 and 17)
	B.	942.5 ohms	
6.	A.	795.8 Hz	(problems 14 and 17)
	B.	1.02 kHz	
7.	5.63 kHz		(problem 19)
8.	711.8 Hz. Assume the internal resistance of the inductor is negligible.		(problem 20)

CHAPTER 6

AC in Electronics

Certain types of circuits are found in most electronic devices used to process alternating current (AC) signals. One of the most common of these, *filter circuits*, is covered in this chapter. Filter circuits are formed by resistors and capacitors (RC), or resistors and inductors (RL). These circuits (and their effect on AC signals) play a major part in communications, consumer electronics, and industrial controls.

When you complete this chapter you will be able to do the following:

- Calculate the output voltage of an AC signal after it passes through a high pass RC filter circuit.
- Calculate the output voltage of an AC signal after it passes through a low pass RC circuit.
- Calculate the output voltage of an AC signal after it passes through a high pass RL circuit.
- Calculate the output voltage of an AC signal after it passes through a low pass RL circuit.
- Draw the output waveform of an AC or combined AC-DC signal after it passes through a filter circuit.
- Calculate simple phase angles and phase differences.

Capacitors in AC Circuits

1 An AC signal is continually changing, whether it is a pure sine wave or a complex signal made up of many sine waves. If such a signal is applied to one plate of a capacitor, it will be induced on the other plate. To express this another way, a capacitor will ''pass'' an AC signal as illustrated in Figure 6-1.

NOTE Unlike an AC signal, a DC signal is blocked by a capacitor. Equally important is the fact that a capacitor is *not* a short circuit to an AC signal.

Figure 6-1

Questions

A. What is the main difference in the effect of a capacitor upon an AC signal versus a DC signal?

____

B. Does a capacitor appear as a short or an open circuit to an AC signal?

____

Answers

A. A capacitor will pass an AC signal, while it will not pass a DC voltage level.

B. Neither

2 A capacitor will, in general, oppose the flow of an AC current to some degree. This opposition to current flow, as you saw in Chapter 5, is called the *reactance* of the capacitor.

Reactance is similar to resistance, except that the reactance of a capacitor changes when you vary the frequency of a signal. The reactance of a capacitor can be calculated by a formula introduced in Chapter 5.

Question

Write the formula for the reactance of a capacitor.

____

Answer

$$X_C = \frac{1}{2\pi fC}$$

3 From this formula, you can see that the reactance changes when the frequency of the input signal changes.

Question

If the frequency increases, what happens to the reactance?

Answer

It decreases.

If you had difficulty with these first three problems, you should review the examples in Chapter 5.

Capacitors and Resistors in Series

4 For simplicity, consider all inputs at this time to be pure sine waves. The circuit shown in Figure 6-2 shows a sine wave as the input signal to a capacitor.

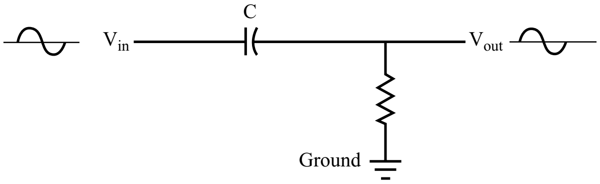

Figure 6-2

Question

If the input is a pure sine wave, what is the output?

Answer

A pure sine wave

5 The output sine wave has the same frequency as the input sine wave. A capacitor cannot change the frequency of the signal. But, remember, with an AC input, the capacitor behaves in a manner similar to a resistor in that the capacitor does have some level of opposition to the flow of alternating current. The level of opposition depends upon the value of the capacitor and the frequency of the signal. Therefore, the output amplitude of a sine wave will be less than the input amplitude.

Question

With an AC input to a simple circuit like the one described here, what does the capacitor appear to behave like?

Answer

It appears to have opposition to alternating current similar to the behavior of a resistor.

6 If you connect a capacitor and resistor in series (as shown in Figure 6-3), the circuit functions as a voltage divider.

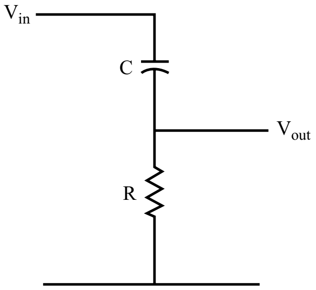

Figure 6-3

Question

What formula would you use to calculate the output voltage for a voltage divider formed by connecting two resistors in series?

Answer

$$V_{out} = V_{in} \times \frac{R_2}{R_1 + R_2}$$

7 You can calculate a total resistance to the flow of electric current for a circuit containing two resistors in series.

Question

What is the formula for this total resistance?

Answer

$R_T = R_1 + R_2$

---

8 You can also calculate the total opposition to the flow of electric current for a circuit containing a capacitor and resistor in series. This parameter is called *impedance*, and you can calculate it using the following formula:

$$Z = \sqrt{X_C^2 + R^2}$$

where:

Z = the impedance of the circuit in ohms

X_C = the reactance of the capacitor in ohms

R = the resistance of the resistor in ohms

Questions

Use the following steps to calculate the impedance of the circuit, and the current flowing through the circuit shown in Figure 6-4.

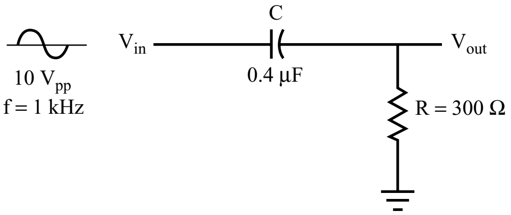

Figure 6-4

A.

$$X_C = \frac{1}{2\pi fC} =$$

B.

$$Z = \sqrt{X_C^2 + R^2} =$$

C.

$$I = \frac{V}{Z} =$$

Answers

A. 400 ohms

B. 500 ohms

C. 20 mA_{pp}

9 Now, for the circuit shown in Figure 6-4, calculate the impedance and current using the values provided.

Questions

A. C = 530 μF, R = 12 ohms, V_{in} = 26 V_{pp}, f = 60 Hz

B. C = 1.77 μF, R = 12 ohms, V_{in} = 150 V_{pp}, f = 10 kHz

Answers

A. Z = 13 ohms, I = 2 A_{pp}

B. Z = 15 ohms, I = 10 A_{pp}

10 You can calculate V_{out} for the circuit shown in Figure 6-5 with a formula similar to the formula used in Chapter 5 to calculate V_{out} for a voltage divider composed of two resistors.

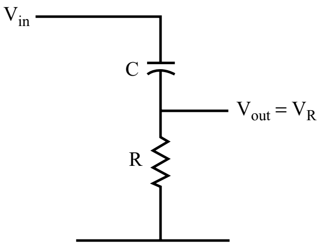

Figure 6-5

The formula to calculate the output voltage for this circuit is as follows:

$$V_{out} = V_{in} \times \frac{R}{Z}$$

Questions

Calculate the output voltage in this circuit using the component values and input signal voltage and frequency listed on the circuit diagram shown in Figure 6-6.

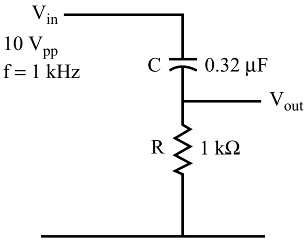

Figure 6-6

A. Find X_C:

B. Find Z:

C. Use the formula to find V_{out}:

Answers

A. $X_C = 500$ ohms (rounded off)

B. $Z = 1120$ ohms (rounded off)

C. $V_{out} = 8.9\ V_{pp}$

11 Now, find V_{out} for the circuit in Figure 6-5 using the given component values, signal voltage, and frequency.

Questions

A. $C = 0.16\ \mu F$, $R = 1\ k\Omega$, $V_{in} = 10\ V_{pp}$, $f = 1\ kHz$

____

B. $C = 0.08\ \mu F$, $R = 1\ k\Omega$, $V_{in} = 10\ V_{pp}$, $f = 1\ kHz$

____

Answers

A. $V_{out} = 7.1\ V_{pp}$

B. $V_{out} = 4.5\ V_{pp}$

NOTE **Hereafter, you can assume that the answer is a peak-to-peak value if the given value is a peak-to-peak value.**

12 The output voltage is said to be *attenuated* in the voltage divider calculations as shown in the calculations in problems 10 and 11. Compare the input and output voltages in problems 10 and 11.

Question

What does *attenuated* mean?

____

Answer

To reduce in amplitude or magnitude (that is, V_{out} is smaller than V_{in}).

13 When you calculated V_{out} in the examples in problems 10 and 11, you first had to find X_C. However, X_C changes as the frequency changes, while the resistance remains constant. Therefore, as the frequency changes, the impedance Z changes, and so also does the amplitude of the output voltage V_{out}.

If V_{out} is plotted against frequency on a graph, the curve looks like that shown in Figure 6-7.

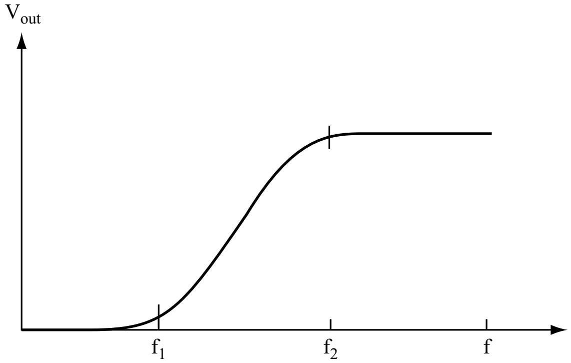

Figure 6-7

The frequencies of f_1 (at which the curve starts to rise) and f_2 (where it starts to level off) depend on the values of the capacitor and the resistor.

Questions

Calculate the output voltage for the circuit shown in Figure 6-8 for frequencies of 100 Hz, 1 kHz, 10 kHz, and 100 kHz.

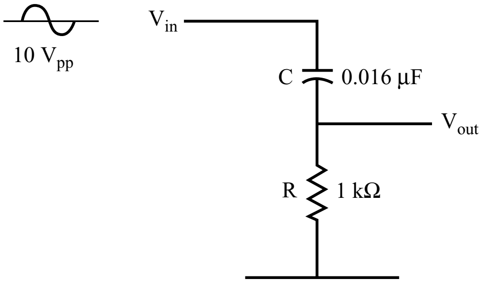

Figure 6-8

A. 100 Hz:

B. 1 kHz:

C. 10 kHz:

D. 100 kHz:

E. Plot these values for V_{out} against f and draw a curve to fit the points. Use a separate sheet of paper to draw your graph.

Answers

A. $V_{out} = 0.1$ V

B. $V_{out} = 1$ V

C. $V_{out} = 7.1$ V

D. $V_{out} = 10$ V

E. The curve is shown in Figure 6-9.

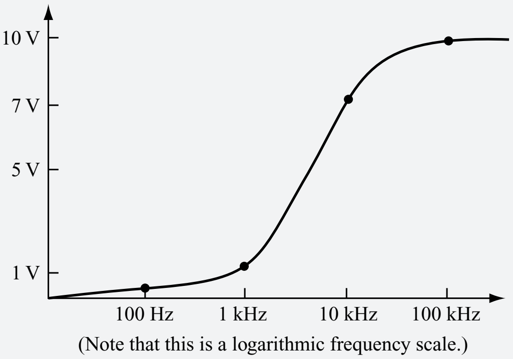

Figure 6-9

NOTE You can see that V_{out} is equal to V_{in} for the highest frequency, and at nearly zero for the lowest frequency. You call this type of circuit a *high pass circuit* because it will pass high frequency signals with little attenuation and block low frequency signals.

The High Pass Filter Experiment

14 The objective of the following experiment is to determine how V_{out} changes as the frequency of the input signal changes for the high pass filter circuit shown in Figure 6-8. You will also calculate X and Z for each frequency value to show the relationship between the output voltage and the impedance.

You will need the following equipment and supplies:

- One 1 kΩ resistor.
- One 0.016 μF capacitor.
- One function generator.
- One oscilloscope. (You can substitute a multimeter and measure V_{out} in rms voltage rather than peak-to-peak voltage.)
- One breadboard.

If you do not have what you need to set up the circuit and measure the values, just read through the experiment.

Follow these steps to complete the experiment:

1. Set up the circuit shown in Figure 6-8 on the breadboard.
2. Set the function generator to generate a 10 V_{pp}, 25 Hz sine wave to be used for V_{in}, measure V_{out} and record the reading in the following table.

f_{in}	X_C	Z	V_{OUT}
25 Hz			
50 Hz			
100 Hz			
250 Hz			
500 Hz			
1 kHz			
3 kHz			
5 kHz			
7 kHz			
10 kHz			
20 kHz			
30 kHz			
50 kHz			
100 kHz			

3. Increase the frequency of V_{in} to the value of f_{in} shown in the next row of the preceding table, measure V_{out} and record the reading in the table. Repeat this until you have entered the value of V_{out} in the last row.

4. Calculate the values of X_C and Z for each row and enter them in the preceding table.
5. Plot V_{out} vs f_{in} with the voltage on the vertical axis and the frequency on the X axis (use graph paper with a log scale for the X axis). The curve should have the same shape as the curve in Figure 6-9, but don't worry if your curve is shifted slightly to the right or left.

Question

What would cause the curve to be moved slightly to the right or the left?

Answer

You may have used a resistor and capacitor with slightly different values than those used to produce the curve shown in Figure 6-10. Such variation in resistor and capacitor values are to be expected, given the manufacturing tolerance allowed for standard components.

Your values should be close to those shown in the following table, and the curve should be very similar to Figure 6-10.

f_{in}	X_C	Z	V_{OUT}
25 Hz	400 kΩ	400 kΩ	0.025 V
50 Hz	200 kΩ	200 kΩ	0.05 V
100 Hz	100 kΩ	100 kΩ	0.1 V
250 Hz	40 kΩ	40 kΩ	0.25 V
500 Hz	20 kΩ	20 kΩ	0.5 V
1 kHz	10 kΩ	10 kΩ	1 V
3 kHz	3.3 kΩ	3.5 kΩ	2.9 V
5 kHz	2 kΩ	2.2 kΩ	4.47 V
7 kHz	1.4 kΩ	1.7 kΩ	5.8 V
10 kHz	1 kΩ	1.414 kΩ	7.1 V
20 kHz	500 Ω	1.12 kΩ	8.9 V
30 kHz	330 Ω	1.05 kΩ	9.5 V
50 kHz	200 Ω	1.02 kΩ	9.8 V
100 kHz	100 Ω	1 kΩ	10 V

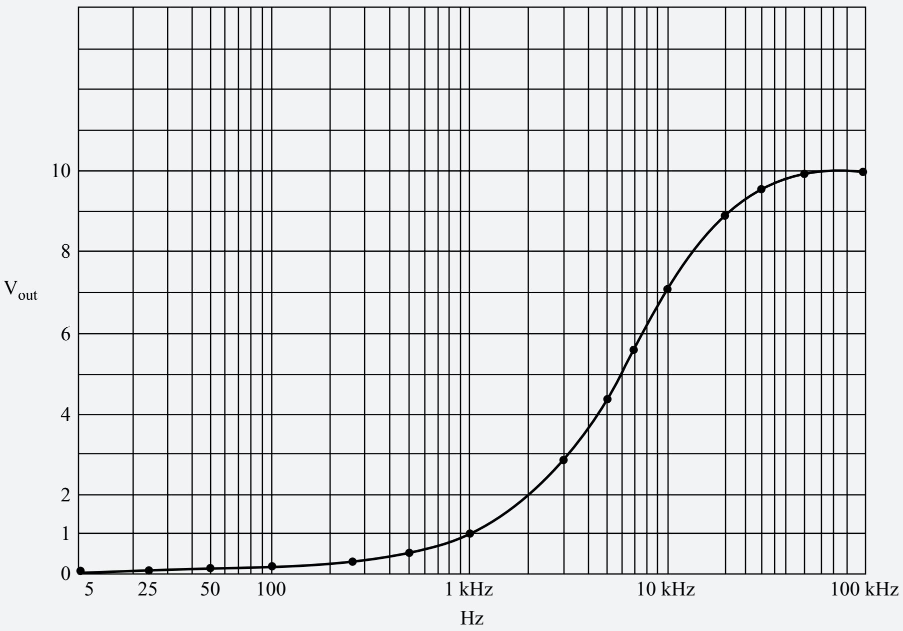

Figure 6-10

Question

What would cause your curve to be moved slightly to the right or the left of the curve shown in Figure 6-10?

Answer

Slightly different values for the resistor and capacitor that you used versus the resistor and capacitor used to produce the curve in Figure 6-10. Variations in resistor and capacitor values are to be expected, given the tolerance allowed for standard components.

15 The circuit shown in Figure 6-11 is used in many electronic devices.

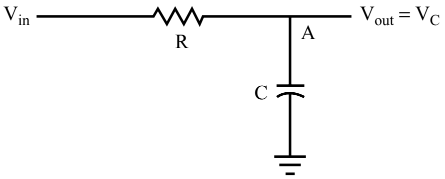

Figure 6-11

For this circuit, you measure the output voltage across the capacitor, instead of across the resistor (between point A and ground).

The impedance of this circuit is the same as that of the circuit used in the last few problems. It will still behave like a voltage divider, and you can calculate the output voltage with an equation that is similar to the one you used for the high pass filter circuit discussed in the last few problems. However, by switching the positions of the resistor and capacitor to create the circuit shown in Figure 6-11, you switch which frequencies will be attenuated and which will not be attenuated, making the new circuit a low pass filter whose characteristics you will explore in the next few problems.

Questions

A. What is the impedance formula for the circuit?

____

B. What is the formula for the output voltage?

____

Answers

A. $Z = \sqrt{X_C^2 + R^2}$

B. $V_{out} = V_{in} \times \frac{X_C}{Z}$

16 Refer to the circuit shown in Figure 6-11 and the following values:

$V_{in} = 10\ V_{pp}, f = 2\,kHz$

$C = 0.1\ \mu F,\ R = 1\,k\Omega$

Questions

Find the following:

A. X_C:

____

B. Z:

C. V_{out}:

Answers

A. 795 ohms

B. 1277 ohms

C. 6.24 V

17 Once again refer to the circuit shown in Figure 6-11 to answer the following question.

Question

Calculate the voltage across the resistor using the values given in problem 16, along with the calculated impedance value.

Answer

$$V_R = V_{in} \times \frac{R}{Z} = 10 \times \frac{1000}{1277} = 7.83V_{pp}$$

18 Use the information from problems 16 and 17 to answer the following question.

Question

What is the formula to calculate V_{in} using the voltages across the capacitor and the resistor?

Answer

The formula is $V_{in}^2 = V_C^2 + V_R^2$.

19 V_{out} of the circuit shown in Figure 6-11 changes as the frequency of the input signal changes. Figure 6-12 shows the graph of V_{out} versus frequency for this circuit.

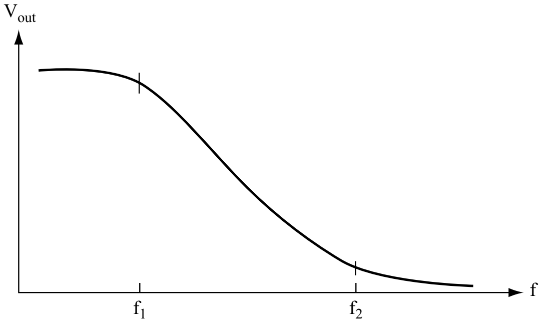

Figure 6-12

Question

What parameters determine f_1 and f_2?

Answer

The values of the capacitor and the resistor

NOTE You can see in Figure 6-12 that V_{out} is large for the lowest frequency, and nearly zero for the highest frequency. You call this type of circuit a *low pass circuit* because it will pass low frequency signals with little attenuation while blocking high frequency signals.

Phase Shift of an RC Circuit

20 In both of the circuits shown in Figure 6-13, the output voltage is different from the input voltage.

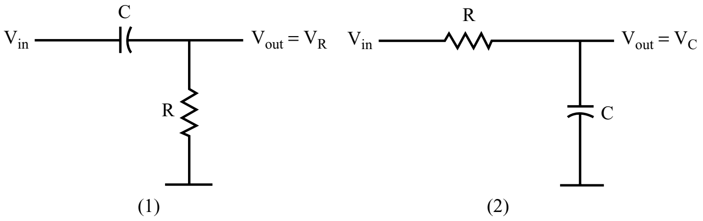

Figure 6-13

Question

In what ways do they differ?

Answer

The signal is attenuated, or reduced. The amount of attenuation depends upon the frequency of the signal.

21 The voltage is also changed in another way. The voltage across a capacitor rises and falls at the same frequency as the input signal, but it does not reach its peak at the same time, nor does it pass through zero at the same time. You can see this when you compare the V_{out} curves to the V_{in} curves in Figure 6-14.

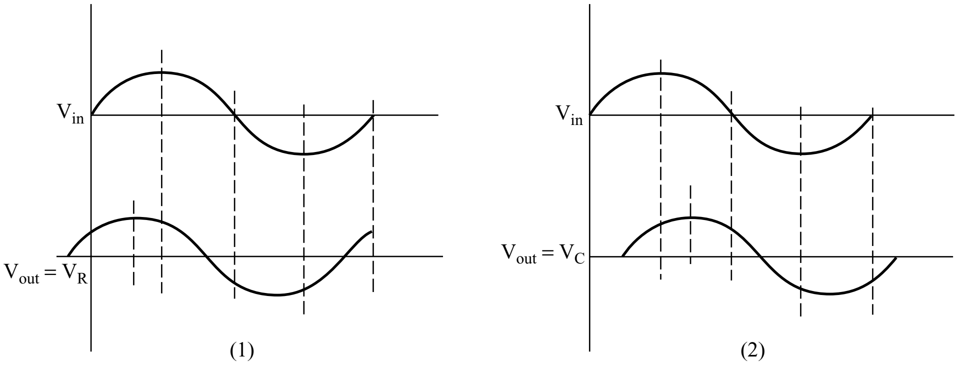

Figure 6-14

NOTE **The numbered graphs in Figure 6-14 are produced by the corresponding numbered circuits in Figure 6-13.**

Questions

A. Examine graph (1). Is the output voltage peak displaced to the right or the left?

B. Examine graph (2). Is the output voltage peak displaced to the right or the left?

Answers

A. To the left

B. To the right

22 The output voltage waveform in graph (1) of Figure 6-14 is said to *lead the input voltage waveform*. The output waveform in graph (2) is said to *lag the input waveform*. The amount that V_{out} leads or lags V_{in} is measured in degrees. There are 90 degrees between the peak of a sine wave and a point at which the sine wave crosses zero volts. You can use this information to estimate the number of degrees V_{out} is leading or lagging V_{in}. The difference between these two waveforms is called a *phase shift* or *phase difference*.

Questions

A. What is the approximate phase shift of the two waveforms shown in the graphs?

____

B. Do you think that the phase shift depends on the value of frequency?

____

C. Will an RC voltage divider with the voltage taken across the capacitor produce a lead or a lag in the phase shift of the output voltage?

____

Answers

A. Approximately 35 degrees.

B. It does depend upon frequency because the values of the reactance and impedance depend upon frequency.

C. A lag as shown in graph (2).

23 The current through a capacitor is out of phase with the voltage across the capacitor. The current leads the voltage by 90 degrees. The current and voltage across a resistor are in phase, that is, they have no phase difference.

Figure 6-15 shows the vector diagram for a series RC circuit. θ is the phase angle by which V_R leads V_{in}. ϕ is the phase angle by which V_C lags V_{in}.

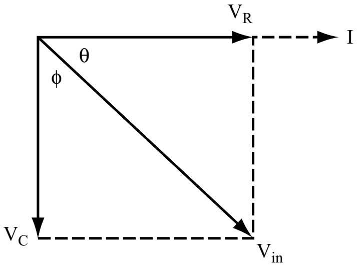

Figure 6-15

NOTE Although the voltage across a resistor is in phase with the current through the resistor, both are out of phase with the applied voltage.

You can calculate the phase angle from this formula:

$$\tan\theta = \frac{V_C}{V_R} = \frac{1}{2\pi fRC} = \frac{X_C}{R}$$

As an example, calculate the phase angle when 160 Hz is applied to a 3.9 kΩ resistor in series with a 0.1 μF capacitor.

$$\tan\theta = \frac{1}{2 \times \pi \times 160 \times 3.9 \times 10^3 \times 0.1 \times 10^{-6}} = 2.564$$

You can calculate the inverse tangent of 2.564 on your calculator and find that the phase angle is 68.7 degrees, which means that V_R leads V_{in} by 68.7 degrees. This also means that V_C lags the input by 21.3 degrees.

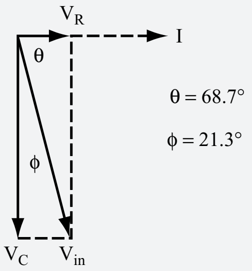
In electronics, the diagram shown in Figure 6-15 is called a *phasor diagram*, but the mathematics involved is the same as for vector diagrams, with which you should be familiar.

Question

Sketch a phasor diagram using the angles θ and ϕ resulting from the calculations in this problem. Use a separate sheet of paper for your diagram.

Answer

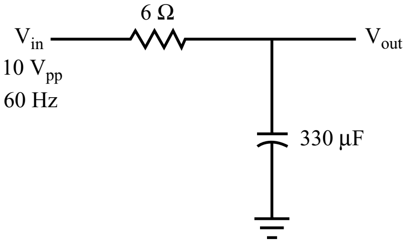
See Figure 6-16. Note that the phasor diagram shows that the magnitude of V_C is greater than V_R.



V_R
I
θ
θ = 68.7°
ϕ = 21.3°
ϕ
V_C
V_{in}

Figure 6-16

24 Using the component values and input signal shown in Figure 6-17, find the following.



6 Ω
V_{in}
10 V_{pp}
60 Hz
V_{out}
330 μF

Figure 6-17

Questions

A. X_C:

____

B. Z:

____

C. V_{out}:

____

D. V_R:

E. The current flowing through the circuit:

F. The phase angle:

Answers

A. $X_C = \frac{1}{2\pi fC} = 8\,\text{ohms}$

B. $Z = \sqrt{8^2 + 6^2} = 10\,\text{ohms}$

C. $V_{out} = V_C = V_{in} \times \frac{X_C}{Z} = 8\,\text{V}$

D. $V_R = V_{in} \times \frac{R}{Z} = 6\,\text{V}$

E. $I = \frac{V}{Z} = \frac{10\,V_{pp}}{10\,\Omega} = 1\,\text{amp}$

F. $\tan\theta = \frac{X_C}{R} = \frac{8\,\Omega}{6\,\Omega} = 1.33.$
Therefore, $\theta = 53.13$ degrees.

25 For the circuit shown in Figure 6-18, calculate the following parameters.

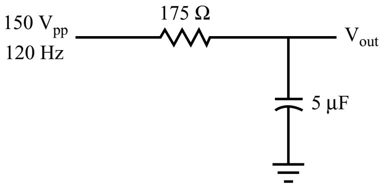


Figure 6-18

Questions

A. X_C:

B. Z:

C. V_{out}:

D. V_R:

E. The current flowing through the circuit:

F. The phase angle:

Answers

A. $X_C = 265$ ohms

B. $Z = \sqrt{175^2 + 265^2} = 317.57\,\Omega$

C. $V_C = 125$ V

D. $V_R = 83$ V

E. $I = 0.472$ A

F. $\tan\theta = \dfrac{265\,\Omega}{175\,\Omega} = 1.5$

Therefore, $\theta = 56.56$ degrees.

Resistor and Capacitor in Parallel

26 The circuit in Figure 6-19 is a common variation on the low pass filter circuit introduced in problem 15.

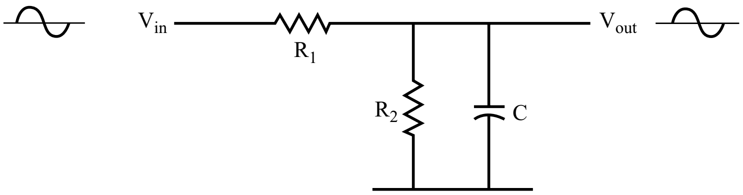

Figure 6-19

Because a DC signal will not pass through the capacitor, this circuit functions like the circuit shown in Figure 6-20 for DC input signals.

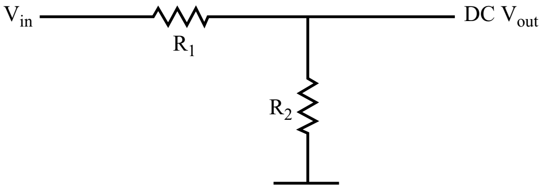

Figure 6-20

An AC signal will pass through both the capacitor and R_2. You can treat the circuit as if it had a resistor with a value of r, where r is the parallel equivalent of R_2 and X_C, in place of the parallel capacitor and resistor. This is shown in Figure 6-21.

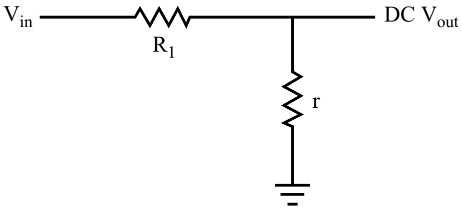

Figure 6-21

Calculating the exact parallel equivalent (r) is very complicated and beyond the scope of this book. However, to demonstrate the usefulness of this circuit let's make a major simplification. Consider a circuit where X_C is only about one tenth the value of R2 or less. This circuit has many practical applications, because it will attenuate the AC and the DC differently.

The following example will help to clarify this. For the following circuit, calculate the AC and DC output voltages separately.

For the circuit shown in Figure 6-22, you can calculate the AC and DC output voltages separately by the steps outlined in the following questions.

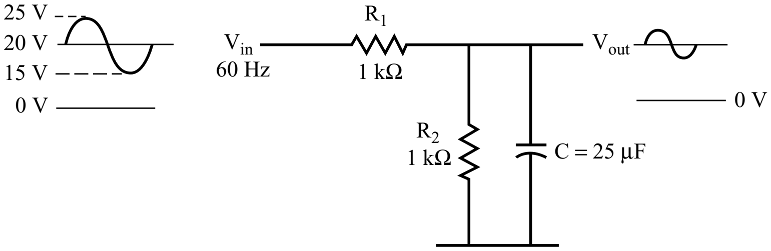

Figure 6-22

Questions

A. Find X_C. Check that it is less than one tenth of R_2.

$X_C =$ ______________________________

B. For the circuit in Figure 6-22, determine which circuit components DC signals will flow through. Then use the voltage divider formula to find DC V_{out}.

DC $V_{out} =$ ______________________________

C. For the circuit in Figure 6-22 determine which circuit components AC signals will flow through. Then use the voltage divider formula to find AC V_{out}.

AC $V_{out} =$ ______________________________

D. Compare the AC and DC input and output voltages.

____

Answers

A. $X_C = 106$ ohms and $R_2 = 1000$ ohms, so X_C is close enough to one tenth of R_2.

B. The portion of the circuit that a DC signal passes through is shown in Figure 6-23.

$$V_{out} = 20 \times \frac{1\,\text{k}\Omega}{1\,\text{k}\Omega + 1\,\text{k}\Omega} = 10\,\text{V}$$

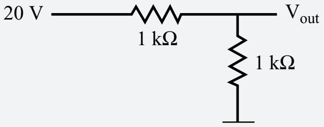

Figure 6-23

C. The portion of the circuit that an AC signal passes through is shown in Figure 6-24.

$$V_{out} = 10 \times \frac{106}{\sqrt{(1000)^2 + (106)^2}} = 1.05\,V$$

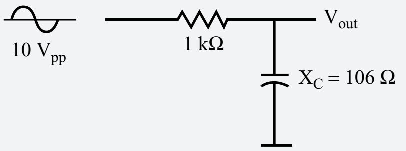

Figure 6-24

D. Figure 6-25 shows the input waveform on the left and the output waveform on the right. You can see from the waveforms that the DC voltage has dropped from 20 V to 10 V, and that the AC voltage has dropped from 10 V to 1.05 V.

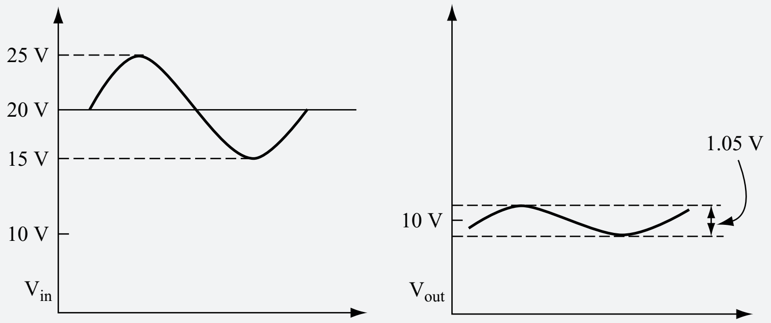

Figure 6-25

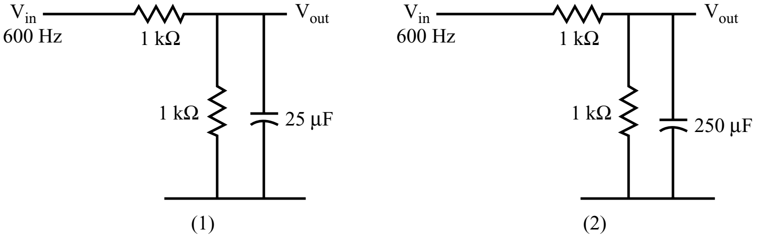
27 Figure 6-26 shows two versions of the circuit discussed in problem 26 with changes to the value of the capacitor or the frequency of the input signal. The input voltage in both cases is 20 V_{pp}. Use the same steps shown in problem 26 to find and compare the output voltages with the input voltages for the two circuits shown in Figure 6-26.



(1) (2)

Figure 6-26

Questions

1. **A.** $X_C =$ ________________________________
   B. DC $V_{out} =$ ________________________________
   C. AC $V_{out} =$ ________________________________
   D. Attenuation: ________________________________
2. **A.** $X_C =$ ________________________________
   B. DC $V_{out} =$ ________________________________
   C. AC $V_{out} =$ ________________________________
   D. Attenuation: ________________________________

Answers

1. **A.** $X_C = 10.6$ ohms.
   B. DC $V_{out} = 10$ V.
   C. AC $V_{out} = 0.1$ V.
   D. Here, the DC attenuation is the same as the example in problem 26, but the AC output voltage is reduced because of the higher frequency.
2. **A.** $X_C = 10.6$ ohms.
   B. DC $V_{out} = 10$ V.
   C. AC $V_{out} = 0.1$ V.
   D. The DC attenuation is still the same, but the AC output voltage is reduced because of the larger capacitor.

Inductors in AC Circuits

28 Figure 6-27 shows a voltage divider circuit using an inductor, rather than a capacitor.

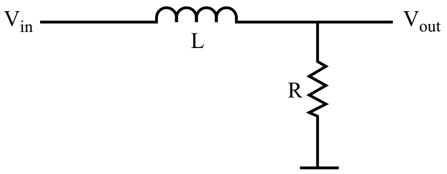


Figure 6-27

As with previous problems, consider all the inputs to be pure sine waves. Like the capacitor, the inductor cannot change the frequency of a sine wave, but it can reduce the amplitude of the output voltage.

The simple circuit, as shown in Figure 6-27, opposes current flow.

Questions

A. What is the opposition to current flow called?

____

B. What is the formula for the reactance of the inductor?

____

C. Write out the formula for the opposition to the current flow for this circuit.

____

Answers

A. Impedance.

B. $X_L = 2\pi fL$.

C. $Z = \sqrt{X_L^2 + R^2}$

In many cases, the DC resistance of the inductor is very low, so assume that it is 0 ohms. For the next two problems make that assumption in performing your calculations.

29 You can calculate the voltage output for the circuit shown in Figure 6-28 with the voltage divider formula.

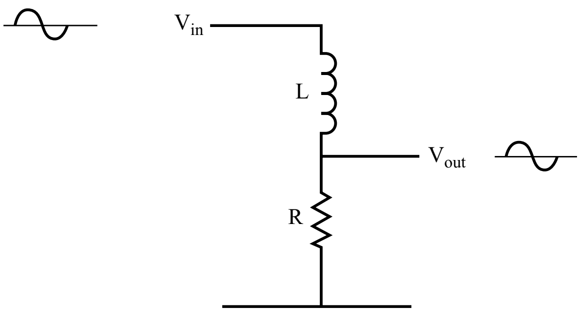

Figure 6-28

Question

What is the formula for V_{out}?

Answer

$$V_{out} = V_{in} \times \frac{R}{Z}$$

30 Find the output voltage for the circuit shown in Figure 6-29.

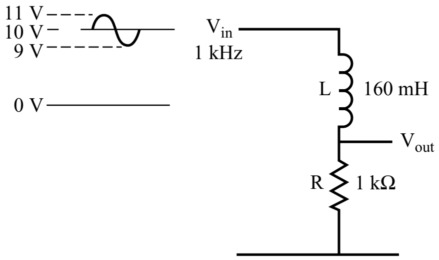

Figure 6-29

Use the steps in the following questions to perform the calculation.

Questions

A. Find the DC output voltage. Use the DC voltage divider formula.

DC V_{out} = ________________

B. Find the reactance of the inductor.

X_L = ________________

C. Find the AC impedance.

Z = ________________

D. Find the AC output voltage.

AC V_{out} = ________________

E. Combine the outputs to find the actual output. Draw the output waveform and label the voltage levels of the waveform on the blank graph in Figure 6-30.

Figure 6-30

Answers

A. DC $V_{out} = 10\,V \times \dfrac{1\,k\Omega}{1\,k\Omega + 0} = 10\,V$

B. $X_L = 1$ kΩ (approximately).

C. $Z = \sqrt{1^2 + 1^2} = \sqrt{2} = 1.414\,k\Omega$

D. AC $V_{out} = 2V_{pp} \times \dfrac{1\,k\Omega}{1.414\,k\Omega} = 1.414\,V_{pp}$

E. The output waveform is shown in Figure 6-31.

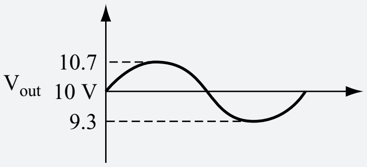

Figure 6-31

31 For the circuit shown in Figure 6-32, the DC resistance of the inductor is large enough that you should include that value in your calculations.

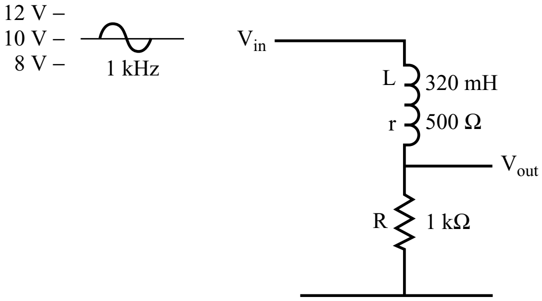

Figure 6-32

Questions

For the circuit shown in Figure 6-32, calculate the DC and AC output voltages, using the steps listed in problem 30.

A. DC V_{out} = ____________________

B. X_L = ____________________

C. Z = ____________________

D. AC V_{out} = ____________________

E. Draw the output waveform and label the voltage levels of the waveform on the blank graph in Figure 6-33.

Figure 6-33

Answers

A. $$\text{DC } V_{out} = 10\text{V} \times \frac{1\,\text{k}\Omega}{(1\,\text{k}\Omega + 500\,\Omega)} = 6.67\,\text{V}$$

NOTE **The 500 Ω DC resistance of the inductor has been added to the 1 kΩ resistor value in this calculation.**

B. $X_L = 2\ \text{k}\Omega$,

C. $Z = \sqrt{1.5^2 + 2^2} = 2.5\,\text{k}\Omega$

NOTE **The 500 Ω DC resistance of the inductor has been added to the 1 kΩ resistor value in this calculation.**

D. AC $V_{out} = 1.6\ V_{pp}$,

E. See Figure 6-34.

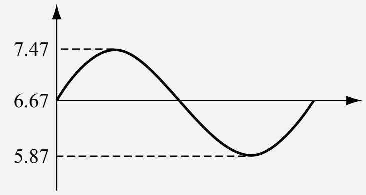

Figure 6-34

32 To calculate V_{out}, in problems 30 and 31, you also had to calculate X_L. However, because X_L changes with the frequency of the input signal, the impedance and the amplitude of V_{out} also change with the frequency of the input signal. Plotting the output voltage V_{out} against frequency results in the curve shown in Figure 6-35.

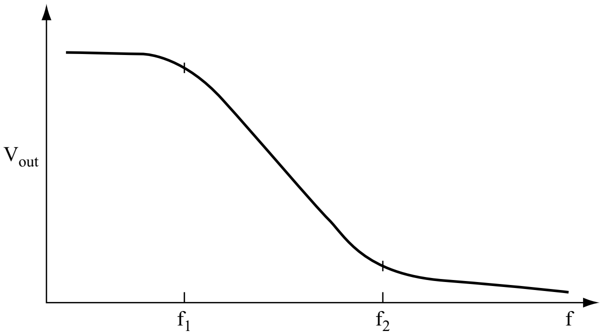

Figure 6-35

The values of the inductor and resistor determine the frequency at which V_{out} starts to drop (f_1) and the frequency at which V_{out} levels off (f_2).

The curve in Figure 6-35 shows that using an inductor and resistor in a circuit such as the one shown in Figure 6-29 produces a low pass filter similar to the one discussed in problems 15 through 19.

Question

What values will control f_1 and f_2?

Answer

The values of the inductor and the resistor

33 You can also create a circuit as shown in Figure 6-36, in which the output voltage is equal to the voltage drop across the inductor.

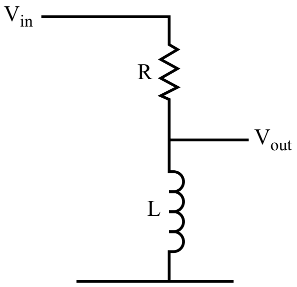

Figure 6-36

Questions

A. What formula would you use to find V_{out}?

B. If you plot the output voltage versus the frequency, what would you expect the curve to be? Use a separate sheet of paper to draw your answer.

Answers

A. $V_{out} = V_{in} \times \frac{X_L}{Z}$

B. See Figure 6-37.

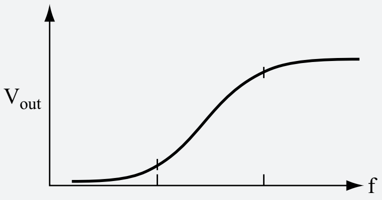

Figure 6-37

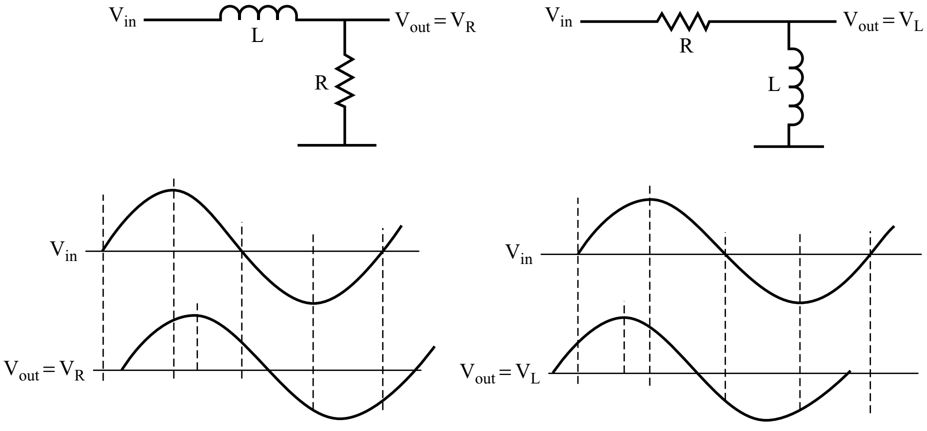
The curve in Figure 6-37 demonstrates that using an inductor and resistor in a circuit, such as the one shown in Figure 6-36, produces a high pass filter similar to the one discussed in problems 6 through 13.

Phase Shift for an RL Circuit

34 Filter circuits that use inductors (such as those shown in Figure 6-38) produce a phase shift in the output signal, just as filter circuits containing capacitors do. You can see the shifts for the circuits shown in Figure 6-38 by comparing the input and output waveforms shown below the circuit diagrams.



(1) (2)

Figure 6-38

Question

In which circuit does the output voltage lead the input voltage?

Answer

In graph (1), the output voltage lags the input voltage, and in graph (2) the output voltage leads.

35 Figure 6-39 shows a vector diagram for both the circuits shown in Figure 6-38. The current through the inductor lags the voltage across the inductor by 90 degrees.

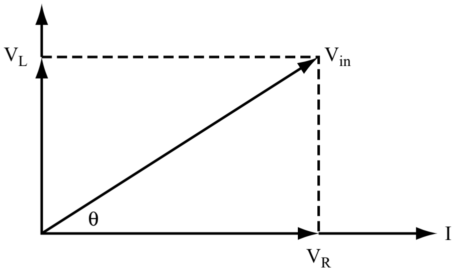


Figure 6-39

The phase angle is easily found:

$$\tan\theta = \frac{V_L}{V_R} = \frac{X_L}{R} = \frac{2\pi fL}{R}$$

Question

Calculate the phase angle for the circuit discussed in problem 30.

Answer

45 degrees

36 Refer to the circuit discussed in problem 31.

Question

Calculate the phase angle.

Answer

$$\tan\theta = \frac{X_L}{R} = \frac{2\,k\Omega}{1.5\,k\Omega} = 1.33$$

Therefore $\theta = 53.1$ degrees.

Summary

This chapter has discussed the uses of capacitors, resistors, and inductors in voltage divider and filter circuits. You learned how to determine the following:

- The output voltage of an AC signal after it passes through a high pass RC filter circuit
- The output voltage of an AC signal after it passes through a low pass RC circuit
- The output voltage of an AC signal after it passes through a high pass RL circuit
- The output voltage of an AC signal after it passes through a low pass RL circuit
- The output waveform of an AC or combined AC-DC signal after it passes through a filter circuit
- Simple phase angles and phase differences

Self-Test

These questions test your understanding of this chapter. Use a separate sheet of paper for your calculations. Compare your answers with the answers provided following the test.

For questions 1–3, calculate the following parameters for the circuit shown in each question.

A. X_C

B. Z

CHAPTER

7

Resonant Circuits

You have seen how the inductor and the capacitor each present an opposition to the flow of an AC current, and how the magnitude of this reactance depends upon the frequency of the applied signal.

When inductors and capacitors are used together, in series or in parallel, a useful phenomenon called *resonance* occurs. Resonance is the frequency at which the reactance of the capacitor and the inductor is equal.

In this chapter, you learn about some of the properties of resonant circuits, and concentrate on those properties that lead to the study of oscillators (which is touched upon in the last few problems in this chapter, and covered in more depth in Chapter 9).

After completing this chapter you will be able to do the following:

- Find the impedance of a series LC circuit.
- Calculate the series LC circuit's resonant frequency.
- Sketch a graph of the series LC circuit's output voltage.
- Find the impedance of a parallel LC circuit.
- Calculate the parallel LC circuit's resonant frequency.
- Sketch a graph of the parallel LC circuit's output voltage.
- Calculate the bandwidth and the Q of simple series and parallel LC circuits.
- Calculate the frequency of an oscillator.

The Capacitor and Inductor in Series

1 Many electronic circuits contain a capacitor and an inductor placed in series, as shown in Figure 7-1.

Figure 7-1

You can combine a capacitor and an inductor in series with a resistor to form voltage divider circuits, such as the two circuits shown in Figure 7-2. A circuit that contains resistance (R), inductance (L), and capacitance (C) is referred to as an RLC circuit. Note that although the order of the capacitor and inductor differs in the two circuits shown in Figure 7-2, in fact, they have the same effect on electrical signals.

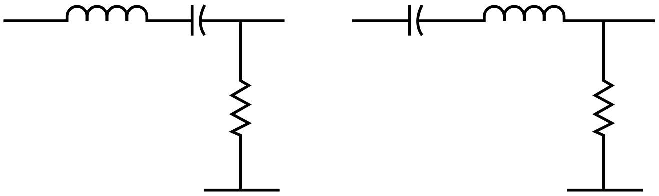

Figure 7-2

To simplify your calculations in the next few problems you can assume that the small DC resistance of the inductor is much less than the resistance of the resistor R, and you can, therefore, ignore DC resistance in your calculations.

When you apply an AC signal to the circuits in Figure 7-2, both the inductor's and the capacitor's reactance value depends on the frequency.

Questions

A. What formula would you use to calculate the inductor's reactance?

____

B. What formula would you use to calculate the capacitor's reactance?

____

Answers

A. $X_L = 2\pi fL$

B. $X_C = \dfrac{1}{2\pi fC}$

2 You can calculate the net reactance (X) of a capacitor and inductor in series using the following formula:

$X = X_L - X_C$

You can calculate the impedance of the RLC circuits shown in Figure 7-2 using the following formula:

$Z = \sqrt{R^2 + X^2}$

In the formula, keep in mind that X^2 is $(X_L + X_C)^2$.

Calculate the net reactance and impedance for an RLC series circuit, such as those shown in Figure 7-2, with the following values:

$f = 1\ \text{kHz}$

$L = 100\ \text{mH}$

$C = 1\ \mu\text{F}$

$R = 500\ \text{ohms}$

Questions

Follow these steps to calculate the following:

A. Find X_L:

____

B. Find X_C:

____

C. Use $X = X_L - X_C$ to find the net reactance:

____

D. Use $Z = \sqrt{X^2 + R^2}$ to find the impedance:

____

Answers

A. $X_L = 628$ ohms

B. $X_C = 160$ ohms

C. $X = 468$ ohms (inductive)

D. $Z = 685$ ohms

3 Calculate the net reactance and impedance for an RLC series circuit, such as those shown in Figure 7-2, using the following values:

$f = 100$ Hz
$L = 0.5$ H
$C = 5\ \mu F$
$R = 8$ ohms

Questions

Follow the steps outlined in problem 2 to calculate the following parameters:

A. $X_L =$ ____________________

B. $X_C =$ ____________________

C. $X =$ ____________________

D. $Z =$ ____________________

Answers

A. $X_L = 314$ ohms

B. $X_C = 318$ ohms

C. $X = -4$ ohms (capacitive)

D. $Z = 9$ ohms

By convention, the net reactance is negative when it is capacitive.

4 Calculate the net reactance and impedance for an RLC series circuit, such as those shown in Figure 7-2, using the following values.

Questions

A. $f = 10$ kHz, $L = 15$ mH, $C = 0.01\ \mu F$, $R = 494$ ohms

$X =$ ____________________

$Z =$ ____________________

B. f = 2 MHz, L = 8 μH, C = 0.001 μF, R = 15 ohms

X = ____________________

Z = ____________________

Answers

A. X = −650 ohms (capacitive), Z = 816 ohms

B. X = 21 ohms (inductive), Z = 25.8 ohms

5 For the circuit shown in Figure 7-3, the output voltage is the voltage drop across the resistor.

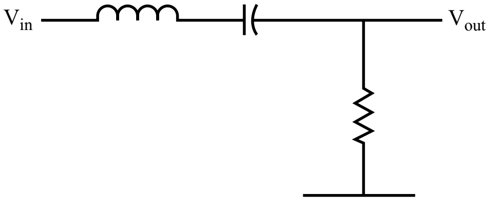

Figure 7-3

In problems 1 through 4, the net reactance of the series inductor and capacitor changes as the frequency changes. Therefore, as the frequency changes, the voltage drop across the resistor changes, and so also does the amplitude of the output voltage V_{out}.

If you plot V_{out} against frequency on a graph for the circuit shown in Figure 7-3, the curve looks like the one shown in Figure 7-4.

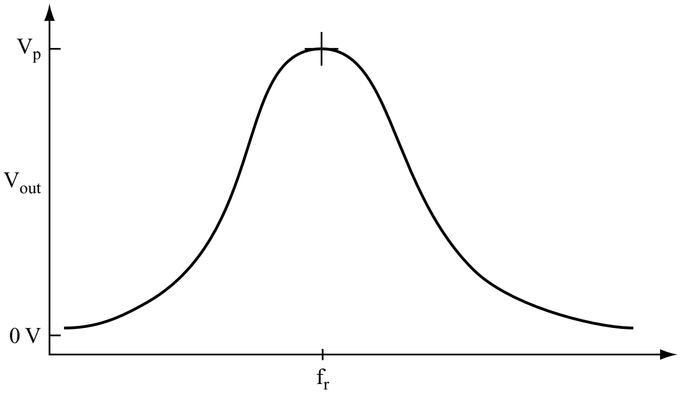

Figure 7-4

The maximum output voltage (or peak voltage) shown in this curve, V_p, is slightly less than V_{in}. This slight attenuation of the peak voltage from the input voltage is because of the DC resistance of the inductor.

The output voltage peaks at a frequency, f_r, where the net reactance of the inductor and capacitor in series is at its lowest value. At this frequency, there is very little voltage drop across the inductor and capacitor. Therefore, most of the input voltage is applied across the resistor, and the output voltage is at its highest value.

Question

Under ideal conditions, if X_C were 10.6 ohms, what value of X_L results in a net reactance (X) of 0 for the circuit shown in Figure 7-3?

Answer

$X = X_L - X_C = 0$, therefore:

$X_L = X_C + X = 10.6\ \Omega + 0 = 10.6\ \Omega$

6 You can find the frequency at which $X_L - X_C = 0$ by setting the formula for X_L equal to the formula for X_C and solving for f:

$$2\pi fL = \frac{1}{2\pi fC}$$

Therefore,

$$f_r = \frac{1}{2\pi\sqrt{LC}}$$

where f_r is the *resonant frequency* of the circuit.

Question

What effect does the value of the resistance have on the resonant frequency?

Answer

It has no effect at all.

7 Calculate the resonant frequency for the circuit shown in Figure 7-3 using the capacitor and inductor values given in the following questions.

Questions

A. C = 1 μF, L = 1 mH

f_r = ____________________

B. C = 16 μF, L = 1.6 mH

f_r = ____________________

Answers

A. $f_r = \dfrac{1}{2\pi\sqrt{1\times 10^{-3}\times 1\times 10^{-6}}} = 5.0\,\text{kHz}$

B. $f_r = \dfrac{1}{2\pi\sqrt{16\times 10^{-6}\times 1.6\times 10^{-3}}} = 1\,\text{kHz}$

8 Calculate the resonant frequency for the circuit shown in Figure 7-3 using the capacitor and inductor values given in the following questions.

Questions

A. C = 0.1 μF, L = 1 mH

f_r = ____________________

B. C = 1 μF, L = 2 mH

f_r = ____________________

Answers

A. f_r = 16 kHz

B. f_r = 3.6 kHz

9 For the RLC circuit shown in Figure 7-5, the output voltage is the voltage drop across the capacitor and inductor.

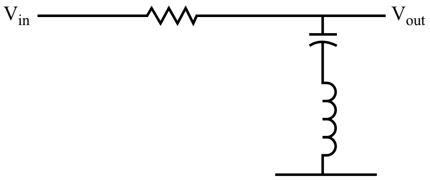

Figure 7-5

If V_{out} is plotted on a graph against the frequency for the circuit shown in Figure 7-5, the curve looks like that shown in Figure 7-6.

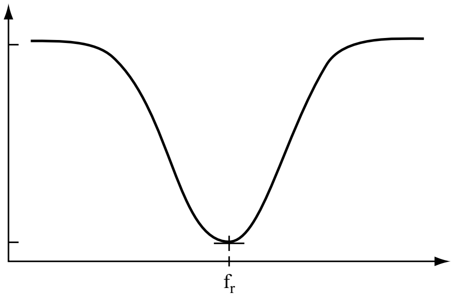

Figure 7-6

The output voltage drops to its minimum value at the resonant frequency for the circuit, which you can calculate with the formula provided in problem 6. At the resonant frequency, the net reactance of the inductor and capacitor in series is at a minimum. Therefore, there is very little voltage drop across the inductor and capacitor, and the output voltage is at its minimum value.

Questions

What would you expect the minimum output voltage to be?

Answers

0 V, or close to it

10 You can connect the capacitor and inductor in parallel, as shown in Figure 7-7.

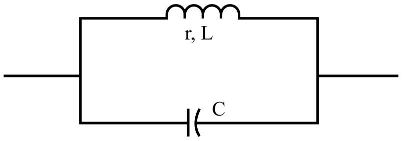

Figure 7-7

You can calculate the resonance frequency of this circuit using the following formula:

$$f_r = \frac{1}{2\pi\sqrt{LC}}\sqrt{1 - \frac{r^2C}{L}}$$

In this formula, r is the DC resistance of the inductor. However, if the reactance of the inductor is equal to or more than 10 times the DC resistance of the inductor, you can use the following simpler formula. This is the same formula that you used in problems 7 and 8 for the series circuit.

$$f_r = \frac{1}{2\pi\sqrt{LC}}$$

The symbol Q is equal to X_L/r. Therefore, you can use this simple equation to calculate f_r if Q is equal to, or greater than, 10.

Questions

A. Which formula should you use to calculate the resonant frequency of a parallel circuit if the Q of the coil is 20?

____

B. If the Q is 8?

____

Answers

A. $f_r = \frac{1}{2\pi\sqrt{LC}}$

B. $f_r = \frac{1}{2\pi\sqrt{LC}}\sqrt{1 - \frac{r^2C}{L}}$

NOTE Here is another version of the resonance frequency formula that is helpful when Q is known:

$$f_r = \frac{1}{2\pi\sqrt{LC}}\sqrt{\frac{Q^2}{1+Q^2}}$$

11 You can calculate the total opposition (impedance) of an inductor and capacitor connected in parallel to the flow of current by using the following formulas for a circuit at resonance:

$Z_p = Q_2r$, if Q is equal to or greater than 10

$Z_p = \frac{L}{rC}$, for any value of Q

At resonance, the impedance of an inductor and capacitor in parallel is at its maximum.

You can use an inductor and capacitor in parallel in a voltage divider circuit, as shown in Figure 7-8.

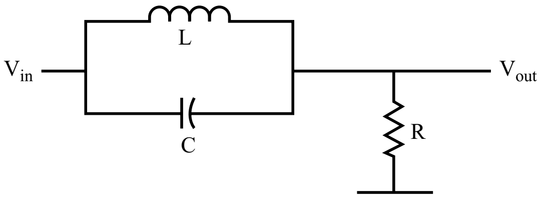

Figure 7-8

If V_{out} is plotted against frequency on a graph for the circuit shown in Figure 7-8, the curve looks like that shown in Figure 7-9.

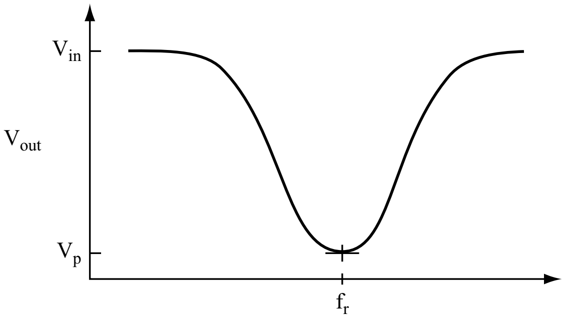

Figure 7-9

Questions

A. What would be the total impedance formula for the voltage divider circuit at resonance?

____

B. What is the frequency called at the point where the curve is at its lowest point?

____

C. Why is the output voltage at a minimum value at resonance?

____

Answers

A. $Z_T = Z_p + R$

NOTE **The relationship shown by this formula is only true at resonance. At all other frequencies, Z_T is a complicated formula or calculation found by considering a series r, L circuit in parallel with a capacitor.**

B. The parallel resonant frequency

C. The output voltage is at its lowest value at the resonant frequency. This is because the impedance of the parallel resonant circuit is at its highest value at this frequency.

12 For the circuit shown in Figure 7-10, the output voltage equals the voltage drop across the inductor and capacitor.

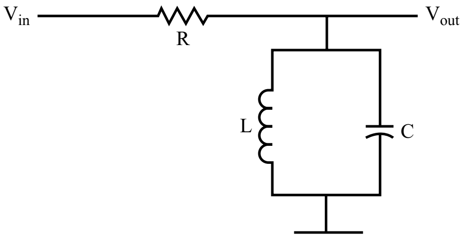

Figure 7-10

If V_{out} is plotted on a graph against frequency for the circuit shown in Figure 7-10, the curve looks like that shown in Figure 7-11. At the resonance frequency, the impedance of the parallel inductor and capacitor is at its maximum value. Therefore, the voltage drop across the parallel inductor and capacitor (which is also the output voltage) is at its maximum value.

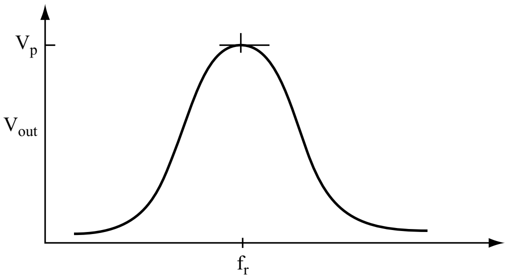

Figure 7-11

Question

What formula would you use to calculate the resonant frequency?

____

Answer

$$f_r = \frac{1}{2\pi\sqrt{LC}} \text{ if Q is equal to or greater than 10}$$

$$f_r = \frac{1}{2\pi\sqrt{LC}}\sqrt{1 - \frac{r^2C}{L}} \text{ if Q is less than 10}$$

13 Find the resonant frequency in these two examples, where the capacitor and the inductor are in parallel. (Q is greater than 10.)

Questions

A. L = 5 mH, C = 5 μF

f_r = ____________________________

B. L = 1 mH, C = 10 μF ________________

f_r = ____________________________

Answers

A. f_r = 1 kHz (approximately)

B. f_r = 1600 Hz (approximately)

The Output Curve

14 Now it's time to look at the output curve in a little more detail. Take a look at the curve shown in Figure 7-12 for an example.

An input signal at the resonant frequency, f_r, passes through a circuit with minimum attenuation and with its output voltage equal to the peak output voltage, V_p, shown on this curve.

The two frequencies f_1 and f_2 are ''passed'' almost as well as f_r is passed. That is, signals at those frequencies have a high output voltage, almost as high as the output of a signal at f_r. The graph shows this voltage as V_x.

Signals at frequencies f_3 and f_4 have a very low output voltage.

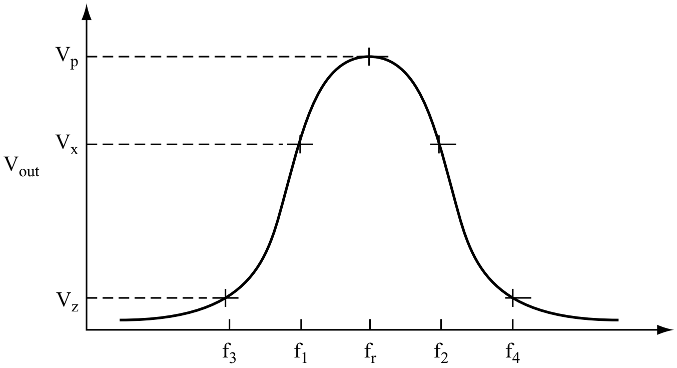

Figure 7-12

These two frequencies are not passed, but are said to be *blocked* or *rejected* by the circuit. This output voltage is shown on the graph as V_z.

The output or frequency response curve for a resonant circuit (series or parallel) has a symmetrical shape for a high value of Q. You can make the assumption that the output curve is symmetrical when Q is greater than 10.

Questions

A. What is meant by a frequency that is passed?

____

B. Why are f_1 and f_2 passed almost as well as f_r?

____

C. What is meant by a frequency that is blocked?

____

D. Which frequencies shown on the previous output curve are blocked?

____

E. Does the output curve shown appear to be symmetrical? What does this mean with regard to the circuit?

____

Answers

A. It appears at the output with minimum attenuation.

B. Because their frequencies are close to f_r.

C. It has a low output voltage.

D. f_3 and f_4 (as well as all frequencies below f_3 and above f_4).

E. It does appear to be symmetrical. This means that the coil has a Q greater than 10.

15 Somewhere between f_r and f_3, and between f_r and f_4, there is a point at which frequencies are said to be either passed or reduced to such a level that it is effectively blocked. The dividing line is at the level at which the power output of the circuit is half as much as the power output at peak value. This happens to occur at a level that is 0.707, or 70.7 percent of the peak value. For the output curve shown in problem 14, this occurs at a voltage level of 0.707 V_p. The two corresponding frequencies taken from the graph are called the *half power frequencies* or *half power points*. These are common expressions used in the design of resonant circuits and frequency response graphs.

If a certain frequency results in an output voltage that is equal to or greater than the half power point, it is said to be passed or accepted by the circuit. If it is lower than the half power point, it is said to be blocked or rejected by the circuit.

Question

Suppose $V_P = 10$ V. What is the minimum voltage level of all frequencies that are passed by the circuit?

Answer

$V = 10\ V \times 0.707 = 7.07\ V$

(If a frequency has an output voltage above 7.07 V, we would say it is passed by the circuit.)

16 Assume the resonant frequency in a circuit is 5 V. Another frequency has an output of 3.3 V.

Question

Is this second frequency passed or blocked by the circuit?

Answer

$V = V_p \times 0.707 = 5 \times 0.707 = 3.535$ V
3.3 V is less than 3.535 V, so this frequency is blocked.

17 In these examples, find the voltage level at the half power points.

Questions

A. $V_p = 20$ V ____________________

B. $V_p = 100$ V ____________________

C. $V_p = 3.2$ V ____________________

Answers

A. 14.14 V

B. 70.70 V

C. 2.262 V

18 Although this discussion started off by talking about the resonance frequency, a few other frequencies have been introduced. In fact, at this point, the discussion is dealing with a band or a range of frequencies.

There are two frequencies that correspond to the half power points on the curve. Assume these frequencies are f_1 and f_2. The difference you find when you subtract f_1 from f_2 is very important, because this gives the range of frequencies that are passed by the circuit. This range is called the *bandwidth* of the circuit, and can be calculated using the following equation.

$$BW = f_2 - f_1$$

All frequencies within the bandwidth are passed by the circuit, while all frequencies outside the bandwidth are blocked. A circuit with this type of output (such as the circuit shown in Figure 7-10) is referred to as a *bandpass filter*.

Question

Indicate which of the following pairs of values represent a wider range of frequencies, or, in other words, the wider bandwidth.

A. $f_2 = 200$ Hz, $f_1 = 100$ Hz

B. $f_2 = 20$ Hz, $f_1 = 10$ Hz

Answer

The bandwidth is wider for the frequencies given in A.

When playing a radio, you listen to one station at a time, not to the adjacent stations on the dial. Thus, your radio tuner must have a narrow bandwidth so that it can select only the frequency of that one station.

The amplifiers in a television set, however, must pass frequencies from 30 Hz up to about 4.5 MHz, which requires a wider bandwidth. The application or use to which you'll put a circuit determines the bandwidth that you should design the circuit to provide.

19 The output curve for a circuit that passes a band of frequencies around the resonance frequency (such as the curve shown in Figure 7-13) was discussed in the last few problems.

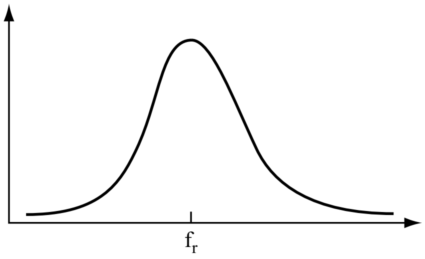

Figure 7-13

The same principles and equations apply to the output curve for a circuit that blocks a band of frequencies around the resonance frequency, as is the case with the curve shown in Figure 7-14.

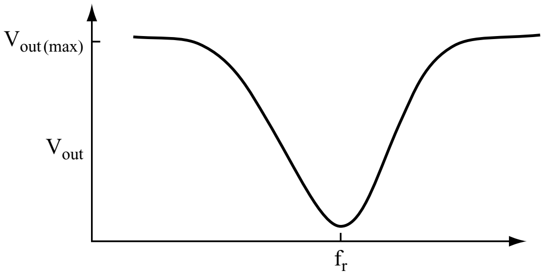

Figure 7-14

A circuit with this type of output (such as the circuit shown in Figure 7-8) is called a *notch filter*, or *band-reject filter*.

Questions

A. What points on the curve shown in Figure 7-14 would you use to determine the circuit's bandwidth?

____

B. Would the output voltage at the resonant frequency be above or below these points?

____

Answers

A. The half power points (0.707 $V_{out(max)}$)

B. The output voltage at the resonant frequency is the minimum point on the curve, which is below the level for the half power points.

20 You can find the bandwidth of a circuit by measuring the frequencies (f_1 and f_2) at which the half power points occur, and then using the following formula:

$$BW = f_2 - f_1$$

Or, you can calculate the bandwidth of a circuit using this formula:

$$BW = \frac{f_r}{Q}$$

where:

$$Q = \frac{X_L}{R}$$

The formula used to calculate bandwidth indicates that, for two circuits with the same resonant frequency, the circuit with the larger Q will have the smaller bandwidth.

When you calculate Q for a circuit containing a capacitor and inductor in series (such as that shown in Figure 7-15) use the total DC resistance — the sum of the DC resistance (r) of the inductor and the value of the resistor (R) — to calculate Q.

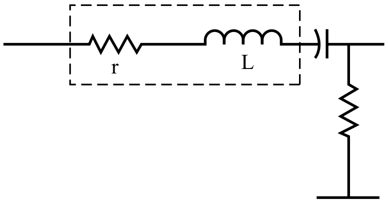

Figure 7-15

When you calculate Q for a circuit containing an inductor and capacitor in parallel, as with the circuit shown in Figure 7-16, you do not include the value of the resistor (R) in the calculation. The only resistance you use in the calculation is the DC resistance (r) of the inductor.

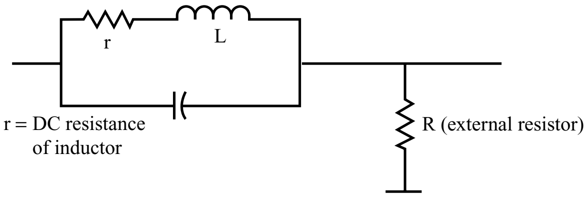

Figure 7-16

When you calculate Q for a circuit containing an inductor, capacitor, and resistor in parallel, as with the two circuits shown in Figure 7-17, include the value of the resistor (R) in the calculation.

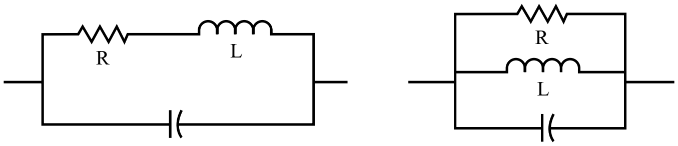

Figure 7-17

Questions

For the circuit shown in Figure 7-18, all the component values are provided in the diagram. Find f_r, Q, and BW.

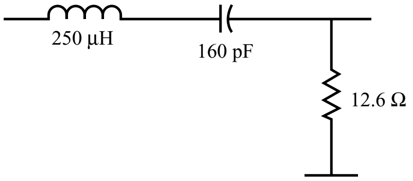

Figure 7-18

$f_r =$ ____

Q = ____

BW = ____

Answers

$$f_r = \frac{1}{2\pi\sqrt{LC}} = \frac{1}{2\pi\sqrt{250 \times 10^{-6} \times 160 \times 10^{-12}}} = 796\,\text{kHZ}$$

$$Q = \frac{X_L}{R} = \frac{2\pi fL}{R} = \frac{2\pi \times 796\,\text{kHz} \times 250\,\mu\text{H}}{12.6\,\Omega} = 99.2$$

$$BW = \frac{f_r}{Q} = \frac{796\,\text{kHz}}{99.2} = 8\,\text{kHz}$$

21 Use the circuit and component values shown in Figure 7-19 to answer the following questions.

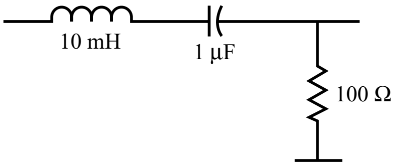

Figure 7-19

Questions

Find f_r, Q, and BW. Then, on a separate sheet of paper, draw an output curve showing the range of frequencies that are passed and blocked.

f_r = ________________________________
Q = ________________________________
BW = ________________________________

Answers

$f_r = 1590$ Hz; Q = 1; BW = 1590 Hz
The output curve is shown in Figure 7-20

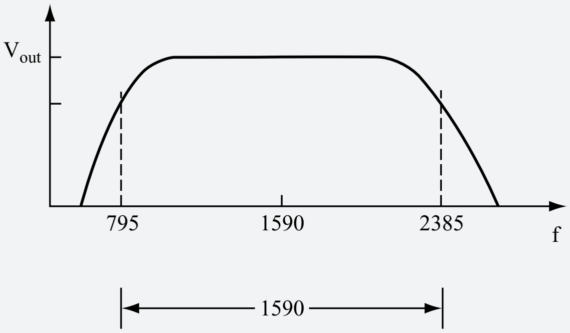

Figure 7-20

22 Use the circuit and component values shown in Figure 7-21 to answer the following questions.

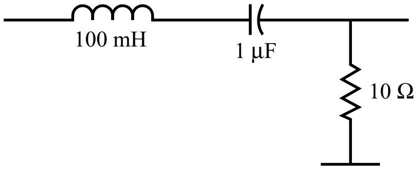

Figure 7-21

Questions

Find f_r, Q, and the bandwidth for this circuit. Then draw the output curve on a separate sheet of paper.

f_r = ____________________

Q = ____________________

BW = ____________________

Answers

$f_r = 500$ Hz; Q = 31.4, BW = 16 Hz

The output curve is shown in Figure 7-22

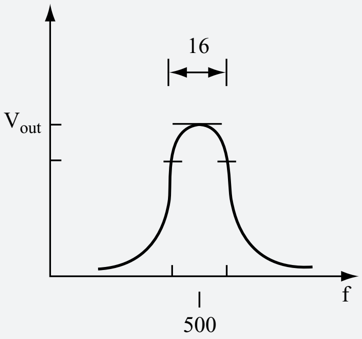

Figure 7-22

23 Use the circuit shown in Figure 7-23 for this problem. In this case, the resistor value is 10 ohms. However, the inductor and capacitor values are not given.

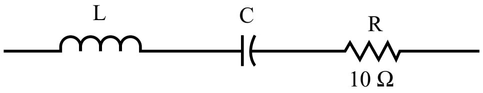

Figure 7-23

Questions

Find the bandwidth and the values of L and C required to give the circuit a resonant frequency of 1200 Hz and a Q of 80.

BW =
L =
C =

Answers

BW = 15 Hz
L = 106 mH
C = 0.166 μF
You can check these values by using the values of L and C to find f_r.

24 Use the circuit shown in Figure 7-23 for this problem. In this case, the resistor value is given as 10 ohms. However, the inductor and capacitor values are not given.

Questions

Calculate the values of Q, L, and C required to give the circuit a resonant frequency of 300 kHz with a bandwidth of 80 kQ.

Q =
L =
C =

Answers

Q = 3.75
L = 20 μH
C = 0.014 μF

25 A circuit that only passes (or blocks) a narrow range of frequencies is called a *high Q* circuit. Figure 7-24 shows the output curve for a high Q circuit.

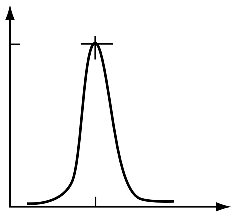

Figure 7-24

Because of the narrow range of frequencies it passes, a high Q circuit is said to be very *selective* in the frequencies it passes.

A circuit that passes (or blocks) a wide range of frequencies is called a *low Q circuit*. Figure 7-25 shows the output curve for a low Q circuit.

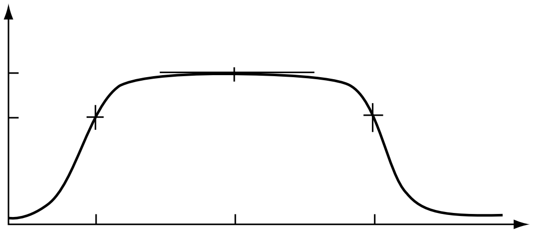

Figure 7-25

Recall the discussion in problem 18 (comparing the bandwidths of radio tuners and television amplifiers) to help you answer the following questions.

Questions

A. Which is the more selective, the radio tuner or the television amplifier?

____

B. Which would require a lower Q circuit, the radio tuner or the television amplifier?

____

Answers

A. The radio

B. The television amplifier

26 The inductor and capacitor in Figure 7-26 are connected in parallel, rather than in series. However, you can use the same formulas you used for the series circuit in problem 20 to calculate f_r, Q, and the bandwidth for parallel LC circuits.

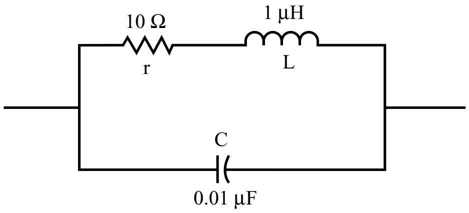

Figure 7-26

Questions

Find f_r, Q, and the bandwidth for the circuit shown in Figure 7-26.

A. f_r = ______________________

B. Q = ______________________

C. BW = ______________________

Answers

A. $f_r = 1.6$ MHz

B. $X_L = 10$ ohms, so $Q = 10/0.01 = 100$ (Note that the only resistance here is the small DC resistance of the inductor.)

C. BW = 16 kHz (This is a fairly high Q circuit.)

27 In the last few problems, you learned how to calculate f_r, BW, and Q, for a given circuit, or conversely, to calculate the component values that would produce a circuit with specified f_r, BW, and Q values.

Once you know the resonant frequency and bandwidth for a circuit, you can sketch an approximate output curve. With the simple calculations listed in this problem, you can draw a curve that is accurate to within 1 percent of its true value.

The curve that results from the calculations used in this problem is sometimes called the *general resonance curve*.

You can determine the output voltage at several frequencies by following these steps:

1. Assume the peak output voltage V_p at the resonant frequency f_r to be 100 percent. This is point A on the curve shown in Figure 7-27.
2. The output voltage at f_1 and f_2 is 0.707 of 100 percent. On the graph, these are the two points labeled B in Figure 7-27. Note that $f_2 - f_1 = \text{BW}$. Therefore, at half a bandwidth above and below f_r, the output is 70.7 percent of V_p.
3. At f_3 and f_4 (the two points labeled C in Figure 7-27), the output voltage is 44.7 percent of V_p. Note that $f_4 - f_3 = 2$ BW. Therefore, at 1 bandwidth above and below f_r, the output is 44.7 percent of maximum.
4. At f_5 and f_6 (the two points labeled D in Figure 7-27), the output voltage is 32 percent of V_p. Note that $f_6 - f_5 = 3$ BW. Therefore, at 1.5 bandwidth above and below f_r, the output is 32 percent of maximum.

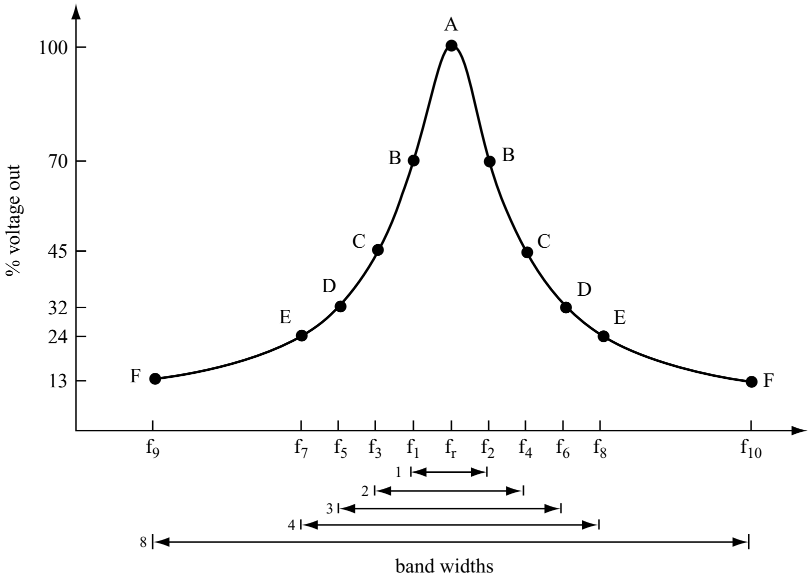

Figure 7-27

5. At f_7 and f_8 (the two points labeled E in Figure 7-27), the output voltage is 24 percent of V_p. Note that $f_8 - f_7 = 4$ BW. Therefore, at 2 bandwidth above and below f_r, the output is 24 percent of maximum.
6. At f_{10} and f_9 (the two points labeled F in Figure 7-27), the output is 13 percent of V_p. Note that $f_{10} - f_9 = 8$ BW. Therefore, at 4 bandwidth above and below $f_{r,}$, the output is 13 percent of maximum.

Questions

Calculate f_r, X_L, Q, and the BW for the circuit shown in Figure 7-28.

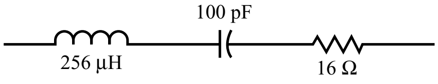

Figure 7-28

$f_r =$ ______________________________
$X_L =$ ______________________________
Q = ______________________________
BW = ______________________________

Answers

$f_r = 1$ MHz
$X_L = 1607$ ohms

$Q = 100$
$BW = 10$ kHz

28 Now, calculate the frequencies that correspond with each percentage of the peak output voltage listed in steps 1 through 6 of problem 27. (Refer to the graph in Figure 7-27 as needed.)

Questions

A. At what frequency will the output level be maximum?

____

B. At what frequencies will the output level be 70 percent of V_p?

____

C. At what frequencies will the output level be 45 percent of V_p?

____

D. At what frequencies will the output level be 32 percent of V_p?

____

E. At what frequencies will the output level be 24 percent of V_p?

____

F. At what frequencies will the output level be 13 percent of V_p?

____

Answers

A. 1 MHz

B. 995 kHz and 1005 kHz (1 MHz − 5 kHz and + 5 kHz)

C. 990 kHz and 1010 kHz

D. 985 kHz and 1015 kHz

E. 980 kHz and 1020 kHz

F. 960 kHz and 1040 kHz

29 You can calculate the output voltage at each frequency in the answers to problem 28 by multiplying the peak voltage by the related percentage for each frequency.

Question

Calculate the output voltage for the frequencies given here, assuming that the peak output voltage is 5 volts.

A. What is the output voltage level at 995 kHz?

B. What is the output voltage level at 980 kHz?

Answer

A. V = 5 V × 0.70 = 3.5 V

B. V = 5 V × 0.24 = 1.2 V

Figure 7-29 shows the output curve generated by plotting the frequencies calculated in problem 28, and the corresponding output voltages calculated in this problem.

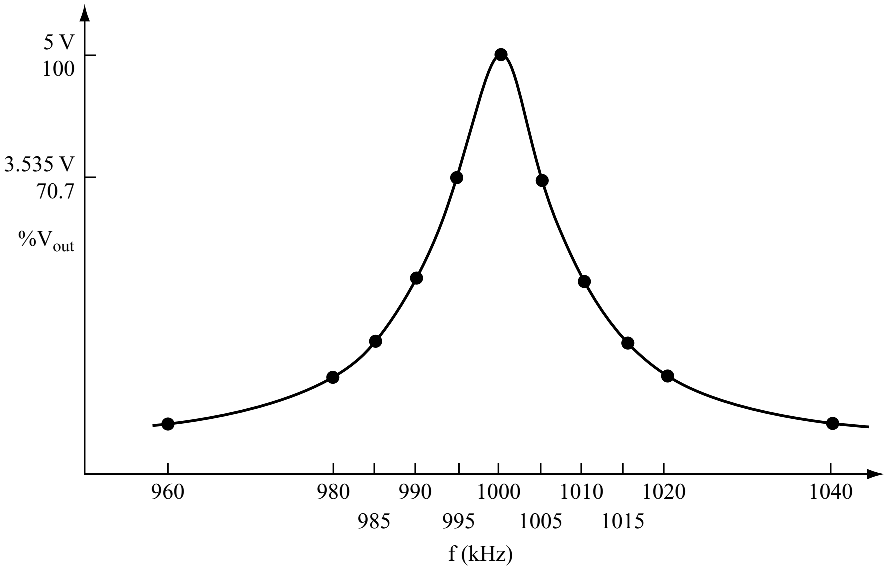

Figure 7-29

Introduction to Oscillators

In addition to their use in circuits used to filter input signals, capacitors and inductors are used in circuits called *oscillators*.

Oscillators are circuits that generate waveforms at particular frequencies. Many oscillators use a tuned parallel LC circuit to produce a sine wave output. This section is an introduction to the use of parallel capacitors and inductors in oscillators.

30 When the switch in the circuit shown in drawing (1) of Figure 7-30 is closed, current flows through both sides of the parallel LC circuit in the direction shown.

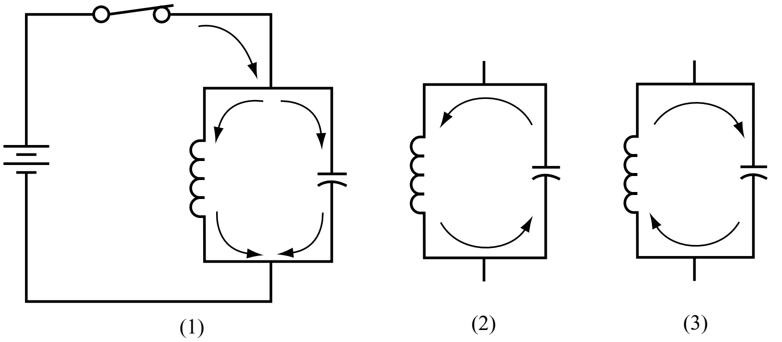

Figure 7-30

It is difficult for the current to flow through the inductor initially, because the inductor opposes any changes in current flow. Conversely, it is easy for the current to flow into the capacitor initially because, with no charge on the plates of the capacitor, there is no opposition to the flow.

As the charge on the capacitor increases, the current flow in the capacitor side of the circuit decreases. However, more current flows through the inductor. Eventually the capacitor is fully charged, so current stops flowing in the capacitor side of the circuit, and a steady current flows through the inductor.

Question

When you open the switch, what happens to the charge on the capacitor?

Answer

It discharges through the inductor. (Note the current direction, shown in drawing (2) of Figure 7-30.)

31 With the switch open, current continues to flow until the capacitor is fully discharged.

Question

When the capacitor is fully discharged, how much current is flowing through the inductor?

Answer

None.

32 Because there is no current in the inductor, its magnetic field collapses. The collapsing of the magnetic field induces a current to flow in the inductor, and this current flows in the same direction as the original current through the inductor (remember that an inductor resists any change in current flow), which is shown in drawing (2) of Figure 7-30. This current now charges the capacitor to a polarity that is opposite from the polarity that the battery induced.

Question

When the magnetic field of the inductor has fully collapsed, how much current will be flowing?

Answer

None.

33 Next, the capacitor discharges through the inductor again, but this time the current flows in the opposite direction, as shown in drawing (3) of Figure 7-30. The change in current direction builds a magnetic field of the opposite polarity. The magnetic field stops growing when the capacitor is fully discharged.

Because there is no current flowing through the inductor, its magnetic field collapses and induces current to flow in the direction shown in drawing (3) of Figure 7-30.

Question

What do you think the current generated by the magnetic field in the inductor will do to the capacitor?

Answer

It charges it to the original polarity.

34 When the field has fully collapsed, the capacitor stops charging. It now begins to discharge again, causing current to flow through the inductor in the direction shown in drawing (2) of Figure 7-30. This ‘‘seesaw’’ action of current will continue indefinitely.

As the current flows through the inductor, a voltage drop occurs across the inductor. The magnitude of this voltage drop will increase and decrease as the magnitude of the current changes.

Question

What would you expect the voltage across the inductor to look like when you view it on an oscilloscope?

Answer

A sine wave

35 In a perfect circuit this oscillation continues and produces a continuous sine wave. In practice, a small amount of power is lost in the DC resistance of the inductor and the other wiring. As a result, the sine wave gradually decreases in amplitude and dies out to nothing after a few cycles, as shown in Figure 7-31.

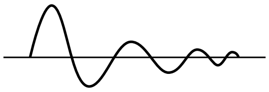

Figure 7-31

Question

How might you prevent this fade out?

Answer

By replacing a small amount of energy in each cycle

This lost energy can be injected into the circuit by momentarily closing and opening the switch at the correct time. (See drawing (1) of Figure 7-30.) This would sustain the oscillations indefinitely.

An electronic switch (such as a transistor) could be connected to the inductor as shown in Figure 7-32. Changes in the voltage drop across the inductor would turn the electronic switch on or off, thereby opening or closing the switch.

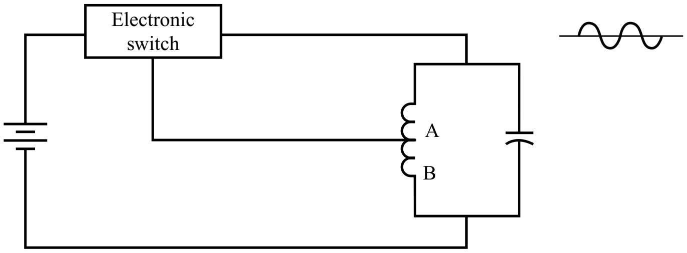

Figure 7-32

The small voltage drop across the few turns of the inductor (also referred to as a *coil*), between point B at the end of the coil and point A about halfway along the coil is used to operate the electronic switch. These points are shown in Figure 7-32.

Using a small part of an output voltage in this way is called feedback because the voltage is ''fed back'' to an earlier part of the circuit to make it operate correctly.

When you properly set up such a circuit, it produces a continuous sine wave output of constant amplitude and constant frequency. This circuit is called an *oscillator*. You can calculate the frequency of the sine waves generated by an oscillator with the following formula for determining resonant frequency:

$$f = \frac{1}{2\pi\sqrt{LC}}$$

The principles you learned in the last few problems are used in practical oscillator circuits, such as those presented in Chapter 9.

Summary

In this chapter, you learned about the following topics related to resonant circuits:

- How the impedance of a series LC circuit and a parallel LC circuit changes with changes in frequency.

- At resonant frequency for a parallel LC circuit, the impedance is at its highest, whereas for a series LC circuit impedance is at its lowest.
- The concept of bandwidth allows you to easily calculate the output voltage at various frequencies and draw an accurate output curve.
- The principles of bandpass filters and notch (or band-reject) filters.
- The fundamental concepts integral to understanding how an oscillator functions.

Self-Test

These questions test your understanding of the concepts covered in this chapter. Use a separate sheet of paper for your drawings or calculations. Compare your answers with the answers provided following the test.

1. What is the formula for the impedance of a series LC circuit?

2. What is the formula for the impedance of a series RLC circuit (a circuit containing resistance, inductance, and capacitance)?

3. What is the relationship between X_C and X_L at the resonant frequency?

4. What is the voltage across the resistor in a series RLC circuit at the resonant frequency?

5. What is the voltage across a resistor in series with a parallel LC circuit at the resonant frequency?

6. What is the impedance of a series circuit at resonance?

7. What is the formula for the impedance of a parallel circuit at resonance?

8. What is the formula for the resonant frequency of a circuit?

9. What is the formula for the bandwidth of a circuit?

10. What is the formula for the Q of a circuit?

Questions 11–13 use a series LC circuit. In each case, the values of the L, C, and R are given. Find f_r, X_L, X_C, Z, Q, and BW. Draw an output curve for each answer.

11. L = 0.1 mH, C = 0.01 μF, R = 10 ohms

12. L = 4 mH, C = 6.4 μF, R = 0.25 ohms

13. L = 16 mH, C = 10 μF, R = 20 ohms

Questions 14 and 15 use a parallel LC circuit. No R is used; r is given. Find f_r, X_L, X_C, Z, Q, and BW.

14. L = 6.4 mH, C = 10 μF, r = 8 ohms

15. L = 0.7 mH, C = 0.04 μF, r = 1.3 ohms

16. Use the output curve shown in Figure 7-33 to answer the following questions.

A. What is the peak value of the output curve?

B. What is the resonant frequency?

C. What is the voltage level at the half power points?

D. What are the half power frequencies?

E. What is the bandwidth?

F. What is the Q of the circuit?

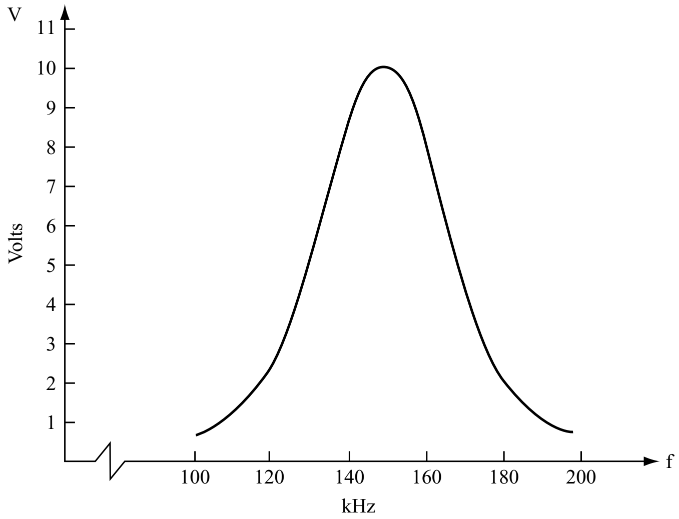

Figure 7-33

Answers to Self-Test

If your answers do not agree with those given here, review the problems indicated in parentheses before you go on to the next chapter.

1.	$Z = X_L - X_C$	(problem 2)
2.	$Z = \sqrt{(X_L - X_C)^2 + R^2}$	(problem 2)
3.	$X_L = X_C$	(problem 5)
4.	Maximum output	(problem 5)
5.	Minimum output	(problem 11)
6.	Z = minimum. Ideally, it is equal to the resistance.	(problem 5)
7.	$Z = \frac{L}{Cr}$	(problem 10)

		In this formula, r is the resistance of the coil.	
8.		$f_r = \frac{1}{2\pi\sqrt{LC}}$	(problem 6)
9.		$BW = \frac{f_r}{Q}$	(problem 20)
10.		$Q = \frac{X_L}{R}$	(problem 20)
		or	
		$\frac{X_L}{r}$	
		To draw the output curves for Questions 11–13, use the graph in Figure 7-27 as a guide and insert the appropriate bandwidth and frequency values.	(problems 21–29)
11.		$f_r = 160$ kHz, $X_L = X_C = 100$ ohms, $Q = 10$, $BW = 16$ kHz, $Z = 10$ ohms	(problems 21–29)
12.		$f_r = 1$ kHz, $X_L = X_C = 25$ ohms, $Q = 100$, $BW = 10$ Hz, $Z = 0.25$ ohms	(problems 21–29)
13.		$f_r = 400$ Hz, $X_L = X_C = 40$ ohms, $Q = 2$, $BW = 200$ Hz, $Z = 20$ ohms	(problems 21–29)
14.		$f_r = 600$ Hz, $X_L = 24$ ohms, $X_C = 26.5$, $Q = 3$, $BW = 200$ Hz, $Z = 80$ ohms	(problems 21–29)
		Because Q is not given, you should use the more complicated of the two formulas shown in Problem 10 to calculate the resonant frequency.	
15.		$f_r = 30$ Hz, $X_L = 132$ ohms, $X_C = 132$, $Q = 101.5$, $BW = 300$ Hz, $Z = 13.4$ ohms	(problems 21–29)
16.			
	A.	10.1 V	(problems 27 and 28)
	B.	148 kHz	(problems 27 and 28)
	C.	$10.1 \times 0.707 = 7.14$ V	(problems 27 and 28)
	D.	Approximately 135 kHz and 160 kHz (not quite symmetrical)	(problems 27 and 28)
	E.	$BW = 25$ kHz	(problems 27 and 28)
	F.	$Q = \frac{f_r}{BW} =$ about 5.9	(problems 27 and 28)

CHAPTER 8

Transistor Amplifiers

Many of the AC signals you'll work with in electronics are very small. For example, the signal that an optical detector reads from a DVD disk cannot drive a speaker, and the signal from a microphone's output is too weak to send out as a radio signal. In cases such as these, you must use an amplifier to boost the signal.

The best way to demonstrate the basics of amplifying a weak signal to a usable level is by starting with a one-transistor amplifier. Once you understand a one-transistor amplifier, you can grasp the building block that makes up amplifier circuits used in electronic devices such as cellphones, MP3 players, and home entertainment centers.

Many amplifier circuit configurations are possible. The simplest and most basic of amplifying circuits are used in this chapter to demonstrate how a transistor amplifies a signal. You will also see the steps for designing an amplifier.

The emphasis in this chapter is on the BJT, just as it was in Chapters 3 and 4 (which dealt primarily with the application of transistors in switching circuits). Two other types of devices used as amplifiers are also examined: the JFET (introduced in Chapters 3 and 4) and an integrated circuit called the *operational amplifier* (*op-amp*).

When you complete this chapter, you will be able to do the following:

- Calculate the voltage gain for an amplifier.
- Calculate the DC output voltage for an amplifier circuit.
- Select the appropriate resistor values to provide the required gain to an amplifier circuit.

- Identify several ways of increasing the gain of a one-transistor amplifier.
- Distinguish between the effects of a standard one-transistor amplifier and an emitter follower circuit.
- Design a simple emitter follower circuit.
- Analyze a simple circuit to find the DC level out and the AC gain.
- Design a simple common source (JFET) amplifier.
- Analyze a JFET amplifier to find the AC gain.
- Recognize an op-amp and its connections.

Working with Transistor Amplifiers

1 In Chapter 3, you learned how to turn transistors ON and OFF. You also learned how to calculate the value of resistors in amplifier circuits to set the collector DC voltage to half the power supply voltage. To review this concept, examine the circuit shown in Figure 8-1.

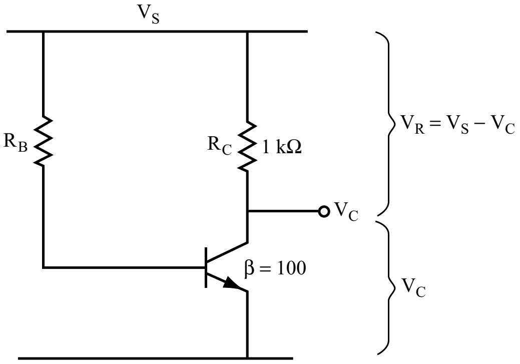

Figure 8-1

Use the following steps to find the value of R_B that will set the collector DC voltage (V_C) to half the supply voltage (V_S).

1. Find I_C by using the following:

$$I_C = \frac{V_R}{R_C} = \frac{V_S - V_C}{R_C}$$

2. Find I_B by using the following:

$$I_B = \frac{I_C}{\beta}$$

3. Find R_B by using the following:

$$R_B = \frac{V_S}{I_B}$$

Questions

Find the value of R_B that will set the collector voltage to 5 V, using Steps 1–3 and the following values for the circuit:

$V_S = 10\,V, \quad R_C = 1\,k\Omega, \quad \beta = 100$

A. $I_C =$ ________________________

B. $I_B =$ ________________________

C. $R_B =$ ________________________

Answers

A. $I_C = \frac{5\,V}{1\,k\Omega} = 5\,mA$

B. $I_B = \frac{5}{100} = 0.05\,mA$

C. $R_B = \frac{10\,V}{0.05\,mA} = 200\,k\Omega$

2 You have seen that using a 200 kΩ resistor for R_B gives an output level of 5 V at the collector. This procedure of setting the output DC level is called *biasing*. In problem 1, you biased the transistor to a 5 V DC output.

Use the circuit shown in Figure 8-1 and the formulas given in problem 1 to answer the following questions.

Questions

A. If you decrease the value of R_B, how do I_B, I_C, V_R, and the bias point V_C change?

____

B. If you increase the value of R_B how do I_B, I_C, V_R, and V_C change?

____

Answers

A. I_B increases, I_C increases, V_R increases, and so the bias point V_C decreases.

B. I_B decreases, I_C decreases, V_R decreases, and so the bias point V_C increases.

3 In problem 2 you found that changing the value of R_B, in the circuit shown in Figure 8-1 changes the value of I_B.

The transistor amplifies slight variations in I_B. Therefore, the amount I_C that fluctuates is β times the change in value in I_B.

The variations in I_C cause changes in the voltage drop V_R across R_C. Therefore, the output voltage measured at the collector also changes.

Questions

For the circuit shown in Figure 8-1, calculate the following parameters when $R_B = 168\ \text{k}\Omega$ and $V_S = 10$ V.

A. $I_B = \dfrac{V_S}{R_B} =$

____

B. $I_C = \beta I_B =$

____

C. $V_R = I_C R_C =$

____

D. $V_C = V_S - V_R =$

____

Answers

A. $I_B = \dfrac{10\ \text{V}}{168\ \text{k}\Omega} = 0.059\ \text{mA}$

B. $I_C = 100 \times 0.059 = 5.9\ \text{mA}$

C. $V_R = 1\ \text{k}\Omega \times 5.9\ \text{mA} = 5.9\ \text{V}$

D. $V_C = 10\ \text{V} - 5.9\ \text{V} = 4.1\ \text{V}$

4 Use the circuit shown in Figure 8-1 to answer the following questions when $V_S = 10$ V.

Questions

Calculate V_C for each of the following values of R_B.

A. 100 kΩ

____

B. 10 MΩ

____

C. 133 kΩ

____

D. 400 kΩ

____

Answers

A. $I_B = 0.1$ mA, $I_C = 10$ mA, $V_C = 0$ V

B. $I_B = 1$ μA, $I_C = 0.1$ mA, $V_C = 10$ V (approximately)

C. $I_B = 0.075$ mA, $I_C = 7.5$ mA, $V_C = 2.5$ V

D. $I_B = 0.025$ mA, $I_C = 2.5$ mA, $V_C = 7.5$ V

5 The values of I_C and V_C that you calculated in problems 1 and 4 are plotted on the graph on the left side of Figure 8-2. The straight line connecting these points on the graph is called the *load line*.

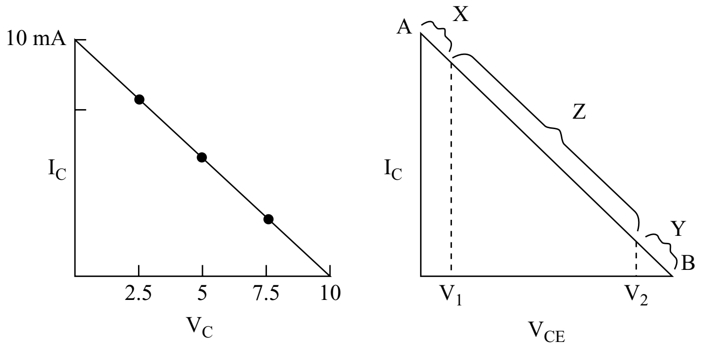

Figure 8-2

The axis labeled V_C represents the voltage between the collector and the emitter of the transistor, and not the voltage between the collector and ground. Therefore, this axis should correctly be labeled V_{CE}, as shown in the graph on the right of the figure. (For this circuit, $V_{CE} = V_C$ because there is no resistor between the emitter and ground.)

Questions

A. At point A in the graph on the right, is the transistor ON or OFF?

B. Is it ON or OFF at point B?

Answers

A. ON because full current flows, and the transistor acts like a short circuit. The voltage drop across the transistor is 0 V.

B. OFF because essentially no current flows, and the transistor acts like an open circuit. The voltage drop across the transistor is at its maximum (10 V, in this case).

6 Point A on the graph shown in Figure 8-2 is called the *saturated point* (or the *saturation point*) because it is at that point that the collector current is at its maximum.

Point B on the graph shown in Figure 8-2 is often called the *cutoff* point because, at that point, the transistor is OFF and no collector current flows.

In regions X and Y, the gain (β) is not constant, so these are called the *nonlinear regions*. Note that $\beta = I_C/I_B$. Therefore, β is the slope of the line shown in the graph.

As a rough guide, V_1 is about 1 V, and V_2 is about 1 V less than the voltage at point B.

Question

What is the value of V_{CE} at point B?

Answer

$V_{CE} = V_S$, which is 10 V in this case.

7 In region Z of the graph shown in Figure 8-2, β (that is, the slope of the graph) is constant. Therefore, this is called the *linear region*. Operating the transistor in the linear region results in an output signal that is free of distortion.

Question

Which values of I_C and V_C would result in an undistorted output in the circuit shown in Figure 8-1?

A. $I_C = 9$ mA, $V_C = 1$ V

B. $I_C = 1$ mA, $V_C = 9$ V

C. $I_C = 6$ mA, $V_C = 4.5$ V

Answer

C is the only one. A and B fall into nonlinear regions.

8 If you apply a small AC signal to the base of the transistor after it has been biased, the small voltage variations of the AC signal (shown in Figure 8-3 as a sine wave) cause small variations in the base current.

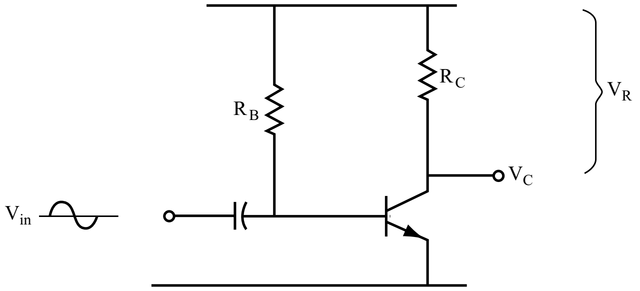

Figure 8-3

These variations in the base current will be amplified by a factor of β, and will cause corresponding variations in the collector current. The variations in the collector current, in turn, will cause similar variations in the collector voltage.

The β used for AC gain calculations is different from the β used in calculating DC variations. The AC β is the value of the common emitter AC forward current transfer ratio, which is listed as h_{fe} in manufacturers' transistor datasheets. Use the AC β whenever you need to calculate the AC output for a given AC input or to determine an AC current variation. Use the DC β to calculate the base or collector DC current values. It is important that you know which β to use and remember that one is used for DC and the other is used for AC variations. The DC β is sometimes called h_{FE} or β_{dc}.

As V_{in} increases, the base current increases, which causes the collector current to increase. An increase in the collector current increases the voltage drop across R_C, which causes V_C to decrease.

NOTE The capacitor shown at the input blocks DC (infinite reactance) and easily passes AC (low reactance). This is a common isolation technique used at the input and output of AC circuits.

Questions

A. If the input signal decreases, what happens to the collector voltage?

B. If you apply a sine wave to the input, what waveform would you expect at the collector?

Answers

A. The collector voltage, V_C, increases.

B. A sine wave, but inverted as shown in Figure 8-4.

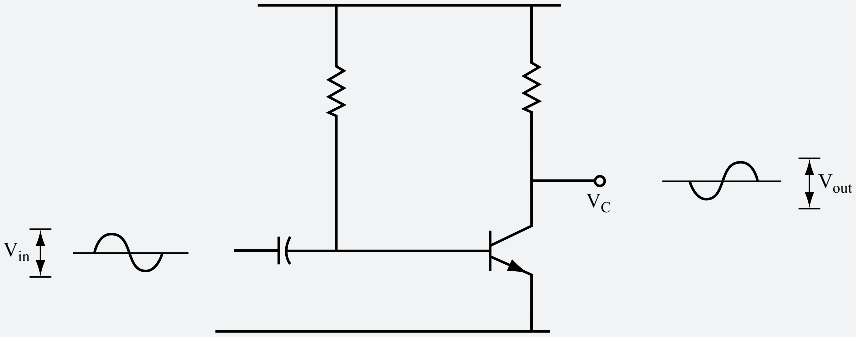

Figure 8-4

9 Figure 8-4 shows the input and output sine waves for an amplifier circuit.

The input voltage V_{in} is applied to the base. (Strictly speaking, it is applied across the base-emitter diode.) The voltage variations at the collector are centered on the DC bias point V_C, and they will be larger than variations in the input voltage. Therefore, the output sine wave is larger than the input sine wave (that is, amplified).

This amplified output signal at the collector can be used to drive a load (such as a speaker).

To distinguish these AC variations in output from the DC bias level, you indicate the AC output voltage by V_{out}. In most cases, V_{out} is a peak-to-peak value.

Questions

A. What is meant by V_C?

____

B. What is meant by V_{out}?

____

Answers

A. Collector DC voltage, or the bias point

B. AC output voltage

The ratio of the output voltage to the input voltage is called the *voltage gain* of the amplifier.

$$\text{Voltage gain} = A_V = \frac{V_{out}}{V_{in}}$$

To calculate the voltage gain of an amplifier, you can measure V_{in} and V_{out} with an oscilloscope. Measure peak-to-peak voltages for this calculation.

10 For the circuit shown in Figure 8-4 you can calculate the voltage gain using the following formula:

$$A_V = \beta \times \frac{R_L}{R_{in}}$$

In this equation:

- R_L = is the *load resistance*. In this circuit, the collector resistor R_C is the load resistance.
- R_{in} = the *input resistance* of the transistor. You can find R_{in} (often called h_{ie}) on the manufacturers' data or specification sheets. In most transistors, input resistance is about 1 kΩ to 2 kΩ.

You can find V_{out} by combining these two voltage gain equations:

$$A_V = \frac{V_{out}}{V_{in}} \quad \text{and} \quad A_V = \beta \times \frac{R_L}{R_{in}}$$

$$\text{Therefore, } \frac{V_{out}}{V_{in}} = \beta \times \frac{R_L}{R_{in}}$$

Solving this for V_{out} results in the following equation. Here, the values of $R_{in} = 1\ k\Omega$, $V_{in} = 1\ mV$, $R_C = 1\ k\Omega$, and $\beta = 100$ were used to perform this sample calculation.

$$\begin{aligned} V_{out} &= V_{in} \times \beta \times \frac{R_L}{R_{in}} \\ &= 1\,mV \times 100 \times \frac{1\,k\Omega}{1\,k\Omega} \\ &= 100\,mV \end{aligned}$$

Questions

A. Calculate V_{out} if $R_{in} = 2\ k\Omega$, $V_{in} = 1\ mV$, $R_C = 1\ k\Omega$, and $\beta = 100$.

____

B. Find the voltage gain in both cases.

____

Answers

A. $V_{out} = 50\ mV$

B. $A_V = 100$ and $A_V = 50$

This simple amplifier can provide voltage gains of up to about 500. But it does have several faults that limit its practical usefulness.

- Because of variations in β between transistors, V_C changes if the transistor is changed. To compensate for this, you will have to adjust R_B.
- R_{in} or h_{ie} varies greatly from transistor to transistor. This variation, combined with variations in β, means that you cannot guarantee the gain from one transistor amplifier to another.
- Both R_{in} and β change greatly with temperature, hence the gain is very temperature-dependent. For example, a simple amplifier circuit like that discussed in this problem was designed to work in the desert in July. It would fail completely in Alaska in the winter. If the amplifier worked perfectly in the lab, it probably would not work outdoors on either a hot or cold day.

NOTE An amplifier whose gain and DC level bias point change as described in this problem is said to be *unstable*. For reliable operation, an amplifier should be as stable as possible. In later problems, you will see how to design a stable amplifier.

The Transistor Amplifier Experiment

In the following experiment, you build a simple transistor amplifier circuit, measure the output voltage and gain, and determine how the output voltage and gain changes with temperature.

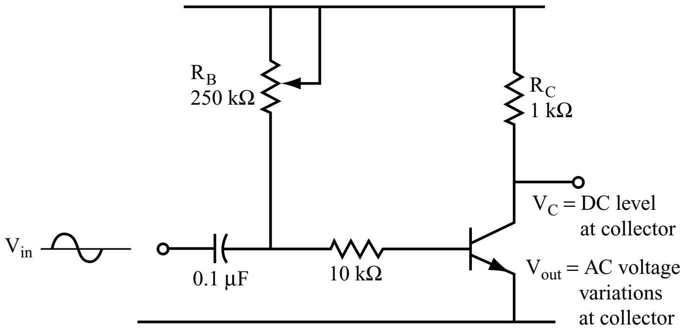
You will need the following equipment and supplies:

- A transistor
- A 250 kΩ potentiometer (that is, a variable resistor)
- A 1 kΩ resistor
- A 10 kΩ resistor
- A 0.1 μF capacitor
- A 9 V transistor radio battery or a lab type power supply
- A breadboard
- A signal generator or a sine wave oscillator
- An oscilloscope

If you do not have what you need to set up the circuit and measure the values, just read through the experiment.

Follow these steps to complete the experiment:

1. Set up the circuit shown in Figure 8-5 on the breadboard.



R_B
250 kΩ
R_C
1 kΩ
V_C = DC level at collector
V_{in}
0.1 μF
10 kΩ
V_{out} = AC voltage variations at collector

Figure 8-5

2. Adjust the potentiometer so that the collector DC level is between 4.5 V and 5 V.
3. Connect the signal generator to the input and adjust the frequency to produce a sine wave output of 1 kHz.

4. Adjust the level of the signal generator so that the output of the transistor at the collector, viewed on an oscilloscope, is not distorted. Make sure the output looks like a sine wave and not like the waveform shown in Figure 8-6.

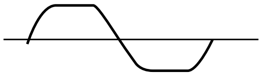


Figure 8-6

5. Measure the pp sine wave input and output of the circuit.
6. Find the voltage gain from the formula $A_V = V_{out}/V_{in}$.
7. Now, heat the transistor while it is in the circuit by placing a soldering iron near it for 15–30 seconds. Note the changes in the DC level at the collector, and the changes in the pp level of the output sine wave.
8. Repeat steps 2–7 with other transistors. Note the differences in gain.

You will discover that you cannot always guarantee in which way the outputs will change. This is because the relative values of β and R_{in} may be different for various transistors, and they may change at different rates as the temperature changes.

It is very important to understand that the bias point and the gain can (and will) change with changes in temperature. Obviously, this limits the practical usefulness of this circuit. To design a usable stable amplifier you must make a few changes, as covered in the next few problems.

A Stable Amplifier

11 You can overcome the instability of the transistor amplifier discussed in the first ten problems of this chapter by adding two resistors to the circuit. Figure 8-7 shows an amplifier circuit to which resistors R_E and R_2 have been added. R_2, along with R_1 (labeled R_B in the previous circuits), ensures the stability of the DC bias point.

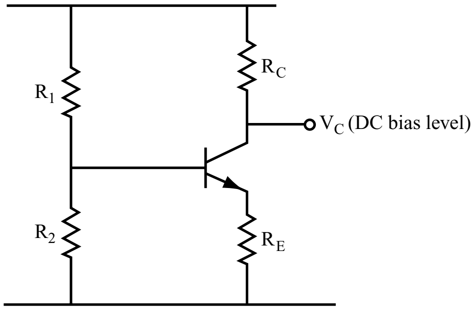

Figure 8-7

By adding the emitter resistor $R_{E,}$ you ensure the stability of the AC gain.

The labels in Figure 8-8 identify the DC currents and voltages present in the circuit. These parameters are used in the next several problems.

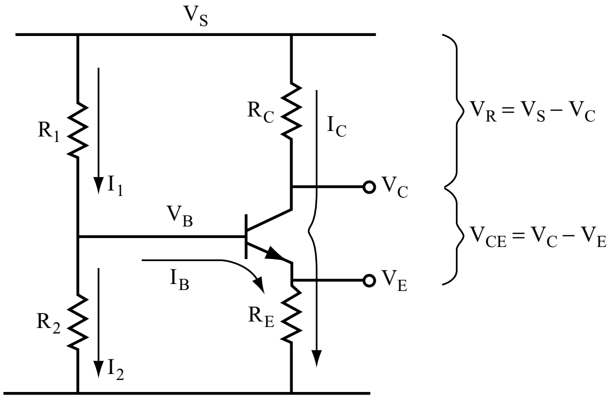

Figure 8-8

Question

In designing an amplifier circuit and choosing the resistor values, there are two goals. What are they?

Answer

A stable DC bias point, and a stable AC gain

12 Look at the gain first. The gain formula for the circuit shown in Figure 8-8 is as follows:

$$A_V = \frac{V_{out}}{V_{in}} = \frac{R_C}{R_E}$$

This is a slight variation on the formula shown in problem 10. (The complex mathematical justification for this is not important right here.) Here, the AC gain has been made independent of the transistor β and input resistance.

As these two parameters vary with temperature, and vary from transistor to transistor, you now have a method of setting the AC gain so that it will be constant regardless of all these variations.

Questions

Use the circuit shown in Figure 8-8 with $R_C = 10\ k\Omega$ and $R_E = 1\ k\Omega$ to answer the following questions.

A. What is the AC voltage gain for a transistor if its $\beta = 100$?

B. What is the gain if $\beta = 500$?

Answers

A. 10

B. 10

13 This problem provides a couple of examples that will help you understand how to calculate voltage gain and the resulting output voltage.

Questions

A. Calculate the voltage gain (A_V) of the amplifier circuit shown in Figure 8-8 if $R_C = 10\text{ k}\Omega$ and $R_E = 1\text{ k}\Omega$. Then, use A_V to calculate the output voltage if the input signal is 2 mV_{pp}.

B. Calculate the voltage gain if $R_C = 1\text{ k}\Omega$ and $R_E = 250$ ohms. Then, use A_V to calculate the output voltage if the input signal is 1 V_{pp}.

Answers

A. $$A_V = \frac{R_C}{R_E} = \frac{10\,\text{k}\Omega}{1\,\text{k}\Omega} = 10$$

$$V_{\text{out}} = 10 \times V_{\text{in}} = 20\,\text{mV}$$

B. $$A_V = \frac{1\,\text{k}\Omega}{250\,\text{ohms}} = 4$$

$$V_{\text{out}} = 4\,V_{\text{pp}}$$

Although the amplifier circuit shown in Figure 8-8 produces stable values of voltage gain, it does not produce high values of voltage gain. For various reasons, this circuit is limited to voltage gains of 50 or less. Later, this chapter discusses an amplifier circuit that can produce higher values of voltage gain.

14 Before you continue, look at the current relationships in the amplifier circuit shown in Figure 8-8 and an approximation that is often made. You can calculate the current flowing through the emitter resistor with the following equation:

$I_E = I_B + I_C$

In other words, the emitter current is the sum of the base and the collector currents.

I_C is much larger than I_B. You can, therefore, assume that the emitter current is equal to the collector current.

$I_E = I_C$

Question

Calculate V_C, V_E, and A_V for the circuit shown in Figure 8-9 with $V_S = 10$ V, $I_C = 1$ mA, $R_C = 1$ kΩ, and $R_E = 100$ ohms.

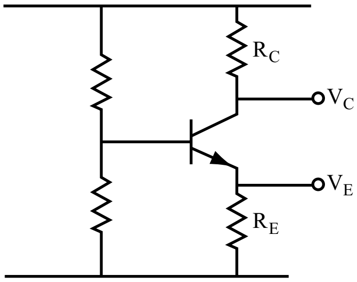

Figure 8-9

Answers

$V_R = 1\,k\Omega \times 1\,mA = 1\,V$

$V_C = V_S - V_R - 10 - 1 = 9\,V$

$V_E = 100\,ohms \times 1\,mA = 0.1\,V$

$$A_V = \frac{R_C}{R_E} = \frac{1\,k\Omega}{100\,ohms} = 10$$

15 For this problem, use the circuit shown in Figure 8-9 with $V_S = 10$ V, $I_C = 1$ mA, $R_C = 2$ kΩ, and $R_E = 1$ kΩ.

Question

Calculate V_C, V_E, and A_V.

Answer

$$V_R = 2\,\text{k}\Omega \times 1\,\text{mA} = 2\,\text{V}$$

$$V_C = 10 - 2 = 8\,\text{V}$$

$$V_E = 1\,\text{k}\Omega \times 1\,\text{mA} = 1\,\text{V}$$

$$A_V = \frac{R_C}{R_E} = \frac{2\,\text{k}\Omega}{1\,\text{k}\Omega} = 2$$

16 For this problem, use the circuit shown in Figure 8-9 with $V_S = 10$ V and $I_C = 1$ mA.

Questions

Find V_C, V_E, and A_V for the following values of R_C and R_E.

A. $R_C = 5$ kΩ, $R_E = 1$ kΩ

B. $R_C = 4.7$ kΩ, $R_E = 220$ ohms

Answers

A. $V_R = 5\,\text{V}$, $V_C = 5\,\text{V}$, $V_E = 1\,\text{V}$, $A_V = 5$

B. $V_R = 4.7\,\text{V}$, $V_C = 5.3\,\text{V}$, $V_E = 0.22\,\text{V}$, $A_V = 21.36$

Biasing

17 In this problem, you see the steps used to calculate the resistor values needed to bias the amplifier circuit shown in Figure 8-10.

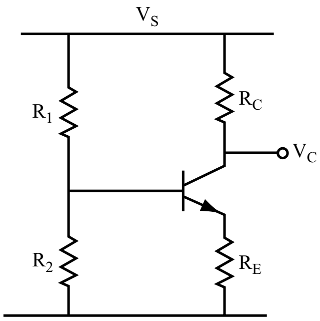

Figure 8-10

You can determine values for R_1, R_2, and R_E that bias the circuit to a specified DC output voltage and a specified AC voltage gain by using the following steps.

Read the following procedure and the relevant formulas first, and then you will walk through an example.

1. Find R_E by using the following:

   $$A_V = \frac{R_C}{R_E}.$$

2. Find V_E by using the following:

   $$A_V = \frac{V_R}{V_E} = \frac{V_S - V_C}{V_E}.$$

3. Find V_B by using the following:

   $$V_B = V_E + 0.7\,V$$

4. Find I_C by using the following:

   $$I_C = \frac{V_S - V_C}{R_C}.$$

5. Find I_B by using the following:

   $$I_B = \frac{I_C}{\beta}$$

6. Find I_2 where I_2 is $10I_B$. (Refer to the circuit shown in Figure 8-8.) This is a convenient rule of thumb that is a crucial step in providing stability to the DC bias point.
7. Find R_2 by using the following:

   $$R_2 = \frac{V_B}{I_2}.$$

8. Find R_1 by using the following:

   $$R_1 = \frac{V_S - V_B}{I_2 + I_B}.$$

9. Steps 7 and 8 might produce nonstandard values for the resistors, so choose the nearest standard values.
10. Use the voltage divider formula to see if the standard values you chose in step 9 result in a voltage level close to V_B found in step 3. (''Close'' means within 10 percent of the ideal.)

This procedure produces an amplifier that works, and results in a DC output voltage and AC gain that are close to those specified at the beginning of the problem.

Questions

Find the values of the parameters specified in each question for the circuit shown in Figure 8-11 if $A_V = 10$, $V_C = 5V$, $R_C = 1\ k\Omega$, $\beta = 100$, and $V_S = 10\ V$.

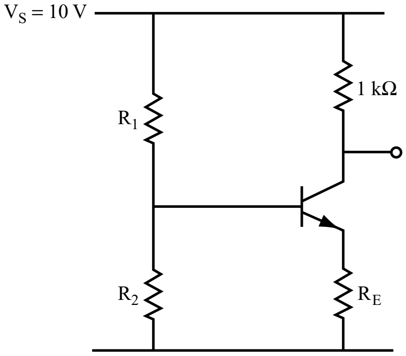

Figure 8-11

Work through steps 1–10, referring to the steps in this problem for formulas as necessary.

1. Find R_E.

   $$A_V = \frac{R_C}{R_E}. \text{ So } R_E = \frac{R_C}{A_V} = \frac{1\,k\Omega}{10} = 100\,\text{ohms}.$$

2. V_E = ____________________________
3. V_B = ____________________________
4. I_C = ____________________________
5. I_B = ____________________________
6. I_2 = ____________________________

7. R_2 = ____________________

8. R_1 = ____________________

9. Choose the standard resistance values that are closest to the calculated values for R_1 and R_2.

R_1 = ____________________; R_2 = ____________________.

10. Using the standard resistance values for R_1 and R_2, find V_B.

V_B = ______________________________________

Answers

You should have found values close to these:

1. 100 ohms
2. 0.5 V
3. 1.2 V
4. 5 mA
5. 0.05 mA
6. 0.5 mA
7. 2.4 kΩ
8. 16 kΩ
9. 2.4 kΩ and 16 kΩ are standard values (they are 5 percent values). Alternative acceptable values would be 2.2 kΩ and 15 kΩ.
10. With 2.4 kΩ and 16 kΩ, $V_B = 1.3$ V. With 2.2 kΩ and 15 kΩ, $V_B = 1.28$ V. Either value of V_B is within 10 percent of the 1.2 V calculated for V_B in step 3.

Figure 8-12 shows an amplifier circuit using the values you calculated in this problem for R_1, R_2, and R_E.

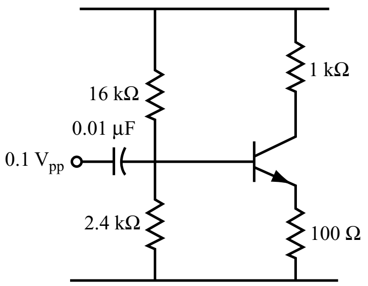

Figure 8-12

18 Follow the steps in problem 17 to answer the following questions.

Questions

Find the values of the parameters specified in each question for the circuit shown in Figure 8-11 if $A_V = 15$, $V_C = 6$ V, $\beta = 100$, $R_C = 3.3$ kΩ, and $V_S = 10$ V.

1. R_E = ______________________
2. V_E = ______________________
3. V_B = ______________________
4. I_C = ______________________
5. I_B = ______________________
6. I_2 = ______________________
7. R_2 = ______________________
8. R_1 = ______________________
9. Choose the standard resistance values that are closest to the calculated values for R_1 and R_2.

   R_1 = ______________________; R_2 = ______________________.
10. Using the standard resistance values for R_1 and R_2, find V_B.

    V_B = ______________________

Answers

These are the values you should have found:

1. 220 ohms
2. 0.27 V
3. 0.97 V (You can use 1 V if you wish.)
4. 1.2 mA
5. 0.012 mA
6. 0.12 mA
7. 8.3 kΩ
8. 68.2 kΩ
9. These are very close to the standard values of 8.2 kΩ and 68 kΩ.
10. 1.08 using the standard values. This is close enough to the value of V_B calculated in question 3.

19 The AC voltage gain for the circuit discussed in problem 18 was 10. Earlier, you learned that the maximum practical gain of the amplifier circuit shown in Figure 8-11 is about 50.

However, in problem 10, you learned that AC voltage gains of up to 500 are possible for the amplifier circuit shown in Figure 8-4. Therefore, by ensuring the stability of the DC bias point, the amplifier has much lower gain than is possible with the transistor amplifier circuit shown in Figure 8-4.

You can make an amplifier with stable bias points without giving up high AC voltage gain by placing a capacitor in parallel with the emitter resistor, as shown in Figure 8-13.

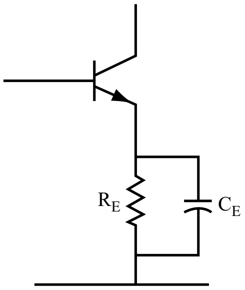

Figure 8-13

If the reactance of this capacitor for an AC signal is significantly smaller than R_E, the AC signal passes through the capacitor rather than the resistor. Therefore, the capacitor is called an *emitter bypass capacitor*. The AC signal ''sees'' a different circuit from the DC, which is blocked by the capacitor and must flow through the resistor. Figure 8-14 shows the different circuits seen by AC and DC signals.

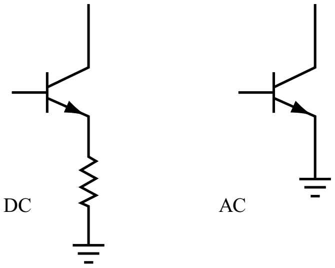

Figure 8-14

The AC voltage gain is now very close to that of the amplifier circuit discussed in problems 1–10.

Questions

A. What effect does the emitter bypass capacitor have on an AC signal?

____

B. What effect does the emitter bypass capacitor have on the AC voltage gain?

____

C. What is the AC voltage gain formula with an emitter bypass capacitor included in the circuit?

Answers

A. It makes the emitter look like a ground, and effectively turns the circuit into the circuit in Figure 8-4.

B. It increases the gain.

C. The same formula used in problem 10:

$$A_V = \beta \times \frac{R_C}{R_{in}}$$

20 You can use the circuit shown in Figure 8-13 when you need as much AC voltage gain as possible. When the volume of AC voltage gain is your priority, predicting the actual amount of gain is usually not important, so the fact that the equation is inexact is unimportant. If you need an accurate amount of gain, then you must use a different type of amplifier circuit that produces lower amounts of gain.

You can find the value of the capacitor C_E using the following steps:

1. Determine the lowest frequency at which the amplifier must operate.
2. Calculate X_C with this formula:

$$X_C = \frac{R_E}{10}$$

3. Calculate C_E with the following formula using the lowest frequency at which the amplifier must operate (determined in step 1):

$$X_C = \frac{1}{2\pi fC}$$

For the following question, use the circuit shown in Figure 8-12, with an emitter bypass capacitor added, as shown in Figure 8-15

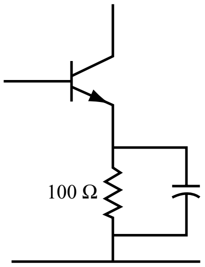

Figure 8-15

Questions

Follow the previous steps to calculate the value of C_E required if the lowest operating frequency of the amplifier is 50 Hz.

1. 50 Hz is the lowest frequency at which the amplifier must operate.
2. $X_C =$ ______________________
3. $C_E =$ ______________________

Answers

$X_C = 10$ ohms

$C_E = 320\ \mu F$ (approximately)

The AC voltage gain formula for an amplifier with an emitter bypass capacitor (Circuit 2 of Figure 8-16) is the same as the AC voltage gain formula for the amplifiers discussed in problems 1–10, where the emitter is directly connected to ground (Circuit 1 of Figure 8-16).

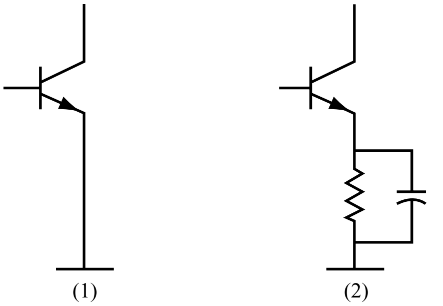

Figure 8-16

The AC voltage gain formula for an amplifier is as follows:

$$A_V = \beta \times \frac{R_C}{R_{in} + R_E}$$

(R_C is being used instead of R_L, because the collector resistor is the total load on the amplifier.)

- *Circuit 1* — Here, $R_E =$ zero, so the AC voltage gain formula is as follows:

  $$A_V = \beta \times \frac{R_C}{R_{in}}.$$

- *Circuit 2* — Here, R_E = zero for an AC signal, because the AC signal is grounded by the capacitor and R_E is out of the AC circuit. Thus, the AC voltage gain formula is as follows:

  $$A_V = \beta \times \frac{R_C}{R_{\text{in}}}.$$

21 To obtain even larger voltage gains, two transistor amplifiers can be *cascaded*. That is, you can feed the output of the first amplifier into the input of the second amplifier. Figure 8-17 shows a two-transistor amplifier circuit, also called a *two-stage amplifier*.

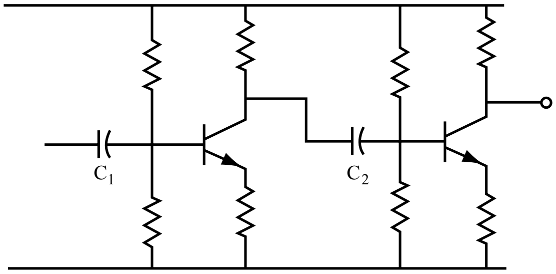

Figure 8-17

You find the total AC voltage gain by multiplying the individual gains. For example, if the first amplifier has an AC voltage gain of 10, and the second has an AC voltage gain of 10, then the overall AC voltage gain is 100.

Questions

A. Suppose you cascade an amplifier with a gain of 15 with one that has a gain of 25. What is the overall gain?

____

B. What is the overall gain if the individual gains are 13 and 17?

____

Answers

A. 375

B. 221

22 Two stage amplifiers can achieve very large AC voltage gains if each amplifier uses an emitter bypass capacitor.

Question

What is the total AC voltage gain if each stage of a two-transistor amplifier has a gain of 100?

Answer

10,000

The Emitter Follower

23 Figure 8-18 shows another type of amplifier circuit.

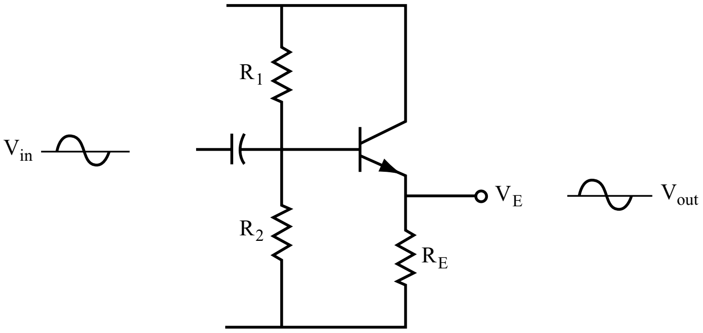

Figure 8-18

Question

How is the circuit shown in Figure 8-18 different from the amplifier circuit discussed in problems 11–18?

Answer

There is no collector resistor, and the output signal is taken from the emitter.

24 The circuit shown in Figure 8-18 is called an *emitter follower* amplifier. (In some cases, it is also called the *common collector* amplifier.)

The output signal has some interesting features:

- The peak-to-peak value of the output signal is almost the same as the input signal. In other words, the circuit gain is slightly less than 1, though in practice it is often considered to be 1.
- The output signal has the same phase as the input signal. It is not inverted. In fact, the output is simply considered to be the same as the input.
- The amplifier has a very high input resistance. Therefore, it draws very little current from the signal source.
- The amplifier has a very low output resistance. Therefore, the signal at the emitter appears to be emanating from a battery or signal generator with a very low internal resistance.

Questions

A. What is the voltage gain of an emitter follower amplifier?

____

B. Is the output signal inverted?

____

C. What is the input resistance of the emitter follower amplifier?

____

D. What is its output resistance?

____

Answers

A. 1

B. No

C. High

D. Low

25 The example in this problem demonstrates the importance of the emitter follower circuit. The circuit shown in Figure 8-19 contains a small AC motor with 100 ohms resistance that is driven by a 10 V_{pp} signal from a generator. The 50 ohm resistor labeled R_G is the internal resistance of the generator.

In this circuit, only 6.7 Vpp is applied to the motor; the rest of the voltage is dropped across R_G.

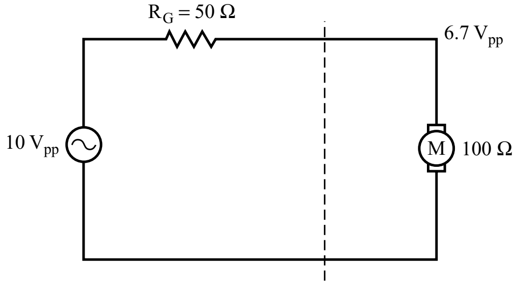

Figure 8-19

Figure 8-20 shows the same circuit, with a transistor connected between the generator and the motor in an emitter follower configuration.

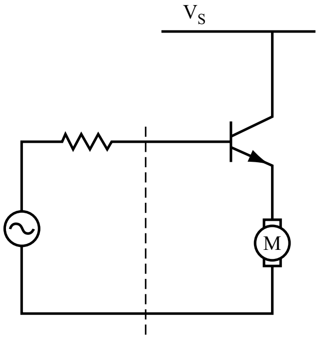

Figure 8-20

You can use the following formula to calculate the approximate input resistance of the transistor.

$R_{in} = \beta \times R_E = 100 \times 100\,\Omega = 10{,}000\,\Omega$ (assuming that $\beta = 100$)

The 10 V_{pp} from the generator is divided between the 10,000 ohm input resistance of the transistor and the 50 ohm internal resistance of the generator. Therefore, there is no significant voltage drop across R_G, and the full 10 V_{pp} is applied to the base of the transistor. The emitter voltage remains at 10 V_{pp}.

Also, the current through the motor is now produced by the power supply and not the generator, and the transistor looks like a generator with a very low internal resistance.

This internal resistance (R_O) is called the *output impedance* of the emitter follower. You can calculate it using this formula:

$$R_O = \frac{\text{internal resistance of generator}}{\beta}$$

for the circuit shown in Figure 8-20, if $R_G = 50$ ohms and $\beta = 100$, $R_O = 0.5$ ohms. Therefore, the circuit shown in Figure 8-20 is effectively a generator with an internal resistance of only 0.5 ohms driving a motor with a resistance of 100 ohms. Therefore, the output voltage of 10 V_{pp} is maintained across the motor.

Questions

A. What is the emitter follower circuit used for in this example?

B. Which two properties of the emitter follower are useful in circuits?

Answers

A. To drive a load that could not be driven directly by a generator

B. High input resistance and its low output resistance

26 The questions in this problem apply to the emitter follower circuit discussed in problems 23–25.

Questions

A. What is the approximate gain of an emitter follower circuit?

B. What is the phase of the output signal compared to the phase of the input signal?

C. Which has the higher value, the input resistance or the output resistance?

D. Is the emitter follower more effective at amplifying signals or at isolating loads?

Answers

A. 1

B. The same phase

C. The input resistance

D. Isolating loads

27 You can design an emitter follower circuit using these steps:

1. Specify V_E. This is a DC voltage level, which is usually specified as half the supply voltage.
2. Find V_B. Use $V_B = V_E + 0.7$ V.
3. Specify R_E. Often this is a given factor, especially if it is a motor or other load that is being driven.
4. Find I_E by using the following:

   $$I_E = \frac{V_E}{R_E}$$

5. Find I_B by using the following:

   $$I_B = \frac{I_E}{\beta}$$

6. Find I_2 by using $I_2 = 10I_B$.
7. Find R_2 by using the following:

   $$R_2 = \frac{V_B}{I_2}.$$

8. Find R_1 by using the following:

   $$R_1 = \frac{V_S - V_B}{I_2 + I_B}.$$

   Usually, I_B is small enough to be dropped from this formula.
9. Choose the nearest standard values for R_1 and R_2.
10. Check that these standard values give a voltage close to V_B. Use the voltage divider formula.

A simple design example illustrates this procedure. Use the values shown in the circuit in Figure 8-21 for this problem.

Questions

Work through Steps 1–10 to find the values of the two bias resistors.

1. V_E = __________
2. V_B = __________
3. R_E = __________

4. I_E = __________
5. I_B = __________
6. I_2 = __________
7. R_2 = __________
8. R_1 = __________
9. The nearest standard values are as follows:
   R_1 = __________ and R_2 = __________
10. V_B = __________

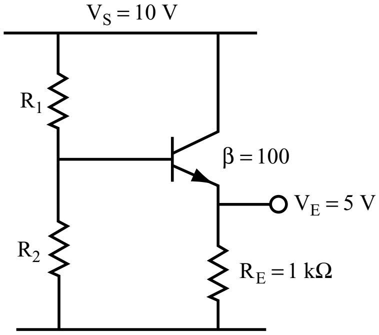

Figure 8-21

Answers

Your answers should be close to these values.

1. 5 V (This was given in Figure 8-21.)
2. 5.7 V
3. 1 kΩ (This was given in Figure 8-21.)
4. 5 mA
5. 0.05 mA
6. 0.5 mA
7. 11.4 kΩ
8. 7.8 kΩ
9. The nearest standard values are 8.2 kΩ and 12 kΩ.

10. The standard resistor values result in $V_B = 5.94$ V. This is a little higher than the V_B calculated in step 2, but it is acceptable.

V_E is set by the biasing resistors. Therefore, it is not dependent upon the value of R_E. Almost any value of R_E can be used in this circuit. The minimum value for R_E is obtained by using this simple equation:

$$R_E = \frac{10\,R_2}{\beta}$$

Analyzing an Amplifier

28 Up to now, the emphasis has been on designing a simple amplifier and an emitter follower. This section shows how to ''analyze'' a circuit that has already been designed. To ''analyze'' in this case means to calculate the collector DC voltage (the bias point) and find the AC gain. This procedure is basically the reverse of the design procedure.

Start with the circuit shown in Figure 8-22.

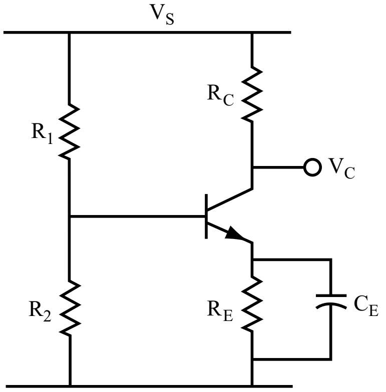

Figure 8-22

Here are the steps you use to analyze a circuit:

1. Find V_B by using the following:

$$V_B = V_S \times \frac{R_2}{R_1 + R_2}.$$

2. Find V_E by using $V_E = V_B - 0.7$ V.

3. Find I_C by using the following:

$$I_C = \frac{V_E}{R_E}.$$

Note that $I_C = I_E$.

4. Find V_R by using $V_R = R_C \times I_C$.
5. Find V_C by using $V_C = V_S - V_R$. This is the bias point.
6. Find A_V by using the following:

$$A_V = \frac{R_C}{R_E} \text{ or } A_V = \beta \times \frac{R_C}{R_{in}}$$

When you use the second formula, you must find the value of R_{in} (or h_{ie}) on the manufacturer's datasheets for the transistor.

Use the circuit shown in Figure 8-23 for following questions. For these questions, use $\beta = 100$, $R_{in} = 2$ kΩ and the values given in the circuit drawing.

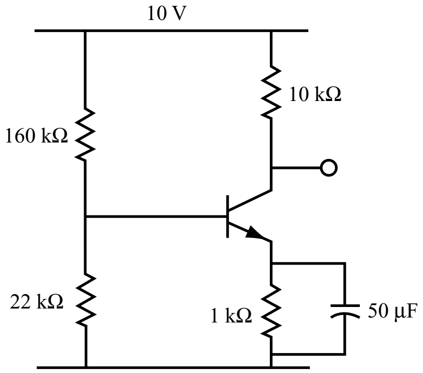

Figure 8-23

Questions

Calculate V_B, V_E, I_C, V_R, V_C, and A_V using steps 1–6 of this problem.

1. V_B = __________
2. V_E = __________
3. I_C = __________
4. V_R = __________
5. V_C = __________
6. A_V = __________

Answers

1. $V_B = 10 \times \dfrac{22\,\text{k}\Omega}{160\,\text{k}\Omega + 22\,\text{k}\Omega} = 1.2\,\text{V}$
2. $V_E = 1.2 - 0.7 = 0.5$ V
3. $I_C = \dfrac{0.5\,\text{V}}{1\,\text{k}\Omega} = 0.5\,\text{mA}$
4. $V_R = 10\ \text{k}\Omega \times 0.5\ \text{mA} = 5$ V
5. $V_C = 10$ V − 5 V = 5 V (This is the bias point.)
6. With the capacitor:

   $A_V = 100 \times \dfrac{10\,\text{k}\Omega}{2\,\text{k}\Omega} = 500$ (a large gain)

   Without the capacitor:

   $A_V = \dfrac{10\,\text{k}\Omega}{1\,\text{k}\Omega} = 10$ (a small gain)

29 You can determine the lowest frequency the amplifier will satisfactorily pass by following these simple steps:

1. Determine the value of R_E.
2. Calculate the frequency at which $X_C = R_E/10$. Use the capacitor reactance formula. (This is one of those ''rules of thumb'' that *can* be mathematically justified, and gives reasonably accurate results in practice.)

Questions

For the circuit shown in Figure 8-23, find the following.

A. R_E = __________

B. f = __________

Answers

A. $R_E = 1$ kΩ (given in the circuit diagram)

B. So, we will set $X_C = 100$ ohms, and use this formula:

$$X_C = \frac{1}{2\pi f C}$$

$$100\,\text{ohms} = \frac{0.16}{f \times 50\,\mu\text{F}} \quad \text{since}\ 0.16 = \frac{1}{2\pi}$$

So:

$$f = \frac{0.16}{100 \times 50 \times 10^{-6}} = 32\,\text{Hz}$$

30 For the circuit shown in Figure 8-24 follow the steps given in problems 28 and 29 to answer the following questions.

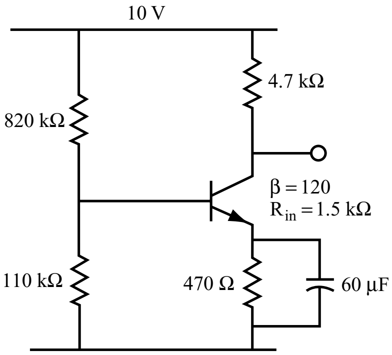

Figure 8-24

Questions

1. V_B = __________
2. V_E = __________
3. I_C = __________
4. V_R = __________
5. V_C = __________
6. With capacitor: A_V = __________

   Without capacitor: A_V = __________
7. Low frequency check: f = __________

Answers

Your answers should be close to these.

1. 1.18 V
2. 0.48 V
3. 1 mA
4. 4.7 V
5. 5.3 V (bias point)
6. With capacitor: 376
   Without capacitor: 10
7. 57 Hz (approximately)

The JFET as an Amplifier

31 Chapter 3 discussed the junction field effect transistor (JFET) in problems 29–32 and Chapter 4 discussed JFET in problems 37–41. You may wish to review these problems before answering the questions in this problem. Figure 8-25 shows a typical biasing circuit for a JFET.

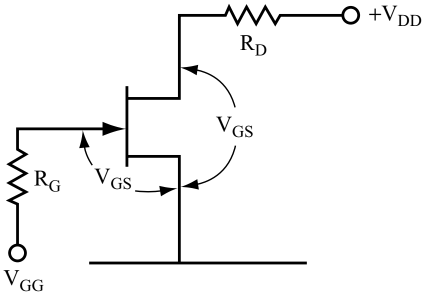

Figure 8-25

Questions

A. What type of JFET is depicted in the circuit?

B. What value of V_{GS} would you need to turn the JFET completely ON?

C. What drain current flows when the JFET is completely ON?

D. What value of V_{GS} would you need to turn the JFET completely OFF?

E. When a JFET is alternately turned completely ON and OFF in a circuit, what type of component are you using the JFET as?

Answers

A. N-channel JFET.

B. $V_{GS} = 0$ V to turn the JFET completely ON.

C. Drain saturation current (I_{DSS}).

D. V_{GS} should be a negative voltage for the N-channel JFET to turn it completely OFF. The voltage must be larger than or equal to the cutoff voltage.

E. The JFET is being used as a switch.

32 You can use a JFET to amplify AC signals by biasing the JFET with a gate to source voltage about halfway between the ON and OFF states. You can find the drain current that flows in a JFET biased to a particular V_{GS} by using the following equation for the transfer curve:

$$I_D = I_{DSS}\left(1 - \frac{V_{GS}}{V_{GS(off)}}\right)^2$$

In this equation, I_{DSS} is the value of the drain saturation current and $V_{GS(off)}$ is the gate to source voltage at cutoff. Both of these are indicated on the transfer curve shown in Figure 8-26.

For the transfer curve shown in Figure 8-26, $I_{DSS} = 12$ mA and $V_{GS(off)} = -4$ V. Setting the bias voltage at $V_{GS} = -2$ V returns the following value for the drain current:

$$I_D = 12\,\text{mA} \times \left(1 - \frac{-2}{-4}\right)^2 = 12\,\text{mA} \times (0.5)^2 = 3\,\text{mA}$$

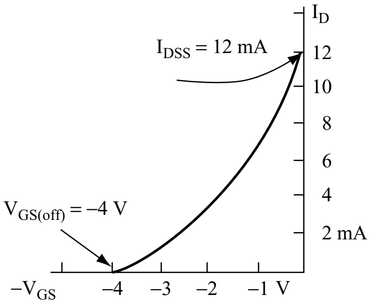

Figure 8-26

Questions

Calculate the drain current for the following:

A. $V_{GS} = -1.5$

B. $V_{GS} = -0.5$ volts.

Answers

A. 4.7 mA

B. 9.2 mA

NOTE **Datasheets give a wide range of possible I_{DSS} and $V_{GS(off)}$) values for a given JFET. You may have to resort to actually measuring these with the method shown in Chapter 4, problem 38.**

33 For the circuit shown in Figure 8-25, you choose the value of the drain to source voltage, V_{DS}, then calculate the value of the load resistor, R_D, by using the following equation:

$$R_D = \frac{(V_{DD} - V_{DS})}{I_D}$$

For this problem, use $I_D = 3$ mA, and a drain supply voltage (V_{DD}) of 24 V. Calculate the value of R_D that results in the specified value of V_{DS}; this is also the DC output voltage of the amplifier.

Question

Calculate the value of R_D that will result in $V_{DS} = 10$ V.

Answer

$$R_D = \frac{(V_{DD} - V_{DS})}{I_D} = \frac{(24\,V - 10V)}{3\,mA} = \frac{14\,V}{3\,mA} = 4.67\,k\Omega$$

34 The circuit shown in Figure 8-27 (which is referred to as a *JFET common source amplifier*) applies a 0.5 V_{pp} sine wave to the gate of the JFET, and produces an amplified sine wave output from the drain.

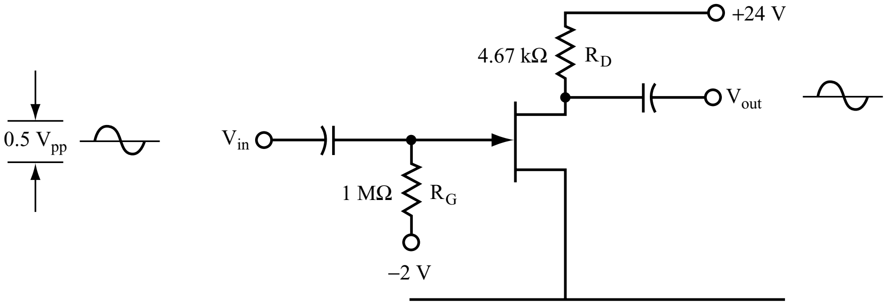

Figure 8-27

The input sine wave is added to the −2 V bias applied to the gate of the JFET. Therefore, V_{GS} varies from −1.75 to −2.25 V.

Question

Calculate I_D, using the formula in problem 32, for the maximum and minimum values of V_{GS}.

Answer

For $V_{GS} = -1.75\,V$, $I_D = 3.8\,mA$.
For $V_{GS} = -2.25\,V$, $I_D = 2.3\,mA$.

35 As the drain current changes, V_{RD} (the voltage drop across resistor R_D) also changes.

Question

For the circuit shown in Figure 8-27, calculate the values of V_{RD} for the maximum and minimum values of I_D you calculated in problem 34.

Answer

For $I_D = 3.8\,\text{mA}, V_{RD} = 3.8\,\text{mA} \times 4.67\,\text{k}\Omega = 17.7\,\text{V}$
For $I_D = 2.3\,\text{mA}, V_{RD} = 2.3\,\text{mA} \times 4.67\,\text{k}\Omega = 10.7\,\text{V}$

This corresponds to a 7 V_{pp} sine wave.

36 As the voltage drop across R_D changes, the output voltage also changes.

Question

For the circuit shown in Figure 8-27, calculate the values of V_{out} for the maximum and minimum values of V_{RD} you calculated in problem 35.

Answer

For $V_{RD} = 17.7\,\text{V},\ V_{out} = V_{DD} - V_{RD} = 24\,\text{V} - 17.7\,\text{V} = 6.3\,\text{V}$
For $V_{RD} = 10.7\,\text{V},\ V_{out} = V_{DD} - V_{RD} = 24\,\text{V} - 10.7\,\text{V} = 13.3\,\text{V}$

Therefore, the output signal is a 7 V_{pp} sine wave.

37 Table 8-1 shows the results of the calculations made in problems 34–36 including the DC bias point.

Table 8-1

V_{GS}	I_D	V_{RD}	V_{OUT}
−1.75 V	3.8 mA	17.7 V	6.3 V
−2.0 V	3.0 mA	14.0 V	10.0 V
−2.25 V	2.3 mA	10.7 V	13.3 V

Question

What are some characteristics of the AC output signal?

Answer

The output signal is a 7 V_{pp} sine wave with the same frequency as the input sine wave. Note that, as the input voltage on V_{GS} increases (toward

0 V), the output decreases. As the input voltage decreases (becomes more negative), the output voltage increases. This means that the output is 180 degrees out of phase with the input.

38 You can calculate the AC voltage gain for the amplifier discussed in problems 34–37 by using the following formula:

$$A_v = \frac{-V_{\text{out}}}{V_{\text{in}}}$$

The negative sign in this formula indicates that the output signal is 180 degrees out of phase from the input signal.

Question

Calculate the AC voltage gain for the amplifier discussed in problems 34–37.

Answer

$$\mathrm{A_V} = \frac{-7\,\mathrm{V_{pp}}}{0.5\,\mathrm{V_{pp}}} = -14$$

39 You can also calculate the AC voltage gain by using the following formula:

$$\mathrm{A_v} = -(\mathrm{g_m})(\mathrm{R_D})$$

In this equation, $\mathrm{g_m}$ is the *transconductance* and is a property of the JFET. It is also called the *forward transfer admittance*. A typical value for $\mathrm{g_m}$ is usually provided for JFETs in the manufacturers' datasheet. You can also use the data in Table 8-1 to calculate $\mathrm{g_m}$ using the following formula:

$$g_m = \frac{\Delta \mathrm{I}_D}{\Delta \mathrm{V}_{GS}}$$

In this equation, Δ indicates the change or variation in $\mathrm{V_{GS}}$ and the corresponding drain current. The unit for transconductance is mhos.

Questions

A. Using the data from Table 8-1, what is the value of $\mathrm{g_m}$ for the JFET used in the amplifier?

____

B. What is the corresponding AC voltage gain?

____

Answers

A. $gm = \dfrac{1.5\,\text{mA}}{0.5\,\text{V}} = 0.003\,\text{mhos}$

B. $A_v = -(0.003)(4670) = -14$, the same result you found in problem 38.

40 Design a JFET common source amplifier using a JFET with $I_{DSS} = 14.8$ mA and $V_{GS(off)} = -3.2$ V. The input signal is 40 mV_{pp}. The drain supply is 24 V.

Questions

A. Determine the value of V_{GS} that will bias the JFET at a voltage near the middle of the transfer curve.

____

B. Calculate the drain current when V_{GS} is at the value determined in step A, using the formula in problem 32.

____

C. Choose a value of V_{DS} and calculate the value of R_D using the formula in problem 33.

____

D. Calculate the maximum and minimum values of V_{GS} that result from the input signal, and the corresponding values of drain current using the procedure in problem 34.

____

E. Calculate the maximum and minimum values of V_{out} that result from the input signal using the procedures in problems 35 and 36.

____

F. Calculate the gain of the amplifier.

____

Answers

A. $V_{GS} = -1.6\ V$

B. $I_D = 3.7\ mA$

C. For $V_{DS} = 10\ V$,

$$R_D = \frac{14\,V}{3.7\,mA} = 3780\,\text{ohms}$$

D. V_{GS} will vary from −1.58 to −1.62 V. Use the formula to calculate values of drain current. I_D will vary from 3.79 to 3.61 mA.

E. V_{RD} will vary from 14.3 to 13.6 V. Therefore, V_{out} will vary from 9.7 to 10.4 V.

F. $A_v = \frac{-0.7}{0.04} = -17.5$

41 Use the results of problem 40, question D, to answer the following question.

Question

Calculate the transconductance of the JFET and the AC voltage gain using the formulas discussed in problem 39.

Answer

$$g_m = \frac{\Delta I_D}{\Delta V_{GS}} = \frac{0.18\,mA}{40\,mV} = 0.0045\,\text{mhos}$$

$$A_v = -(g_m)(R_D) = -(0.0045)(3780) = -17$$

This is very close to the value you found in problem 40, question F.

42 Figure 8-28 shows a JFET amplifier circuit that uses one power supply, rather than separate power supplies for the drain and gate used in the amplifier discussed in problems 34–41.

The DC voltage level of the gate is zero because the gate is tied to ground through R_G. Therefore, the voltage drop across R_S becomes the gate to source voltage. To design the circuit, you must find values for both R_S and R_D. Use the same bias point for this problem as you used for the amplifier discussed in problems 34–41: $V_{GS} = -2$ V and $I_D = 3$ mA. Follow these steps:

1. Calculate R_S, using the following formula, recognizing that $V_{RS} = V_{GS}$:

$$R_S = \frac{V_{RS}}{I_D} = \frac{V_{GS}}{I_D}$$

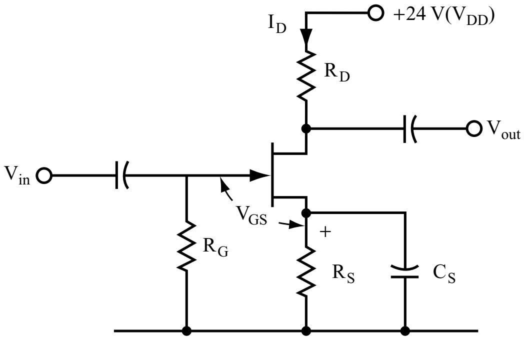

Figure 8-28

2. Calculate R_D using the following formula, using $V_{DS} = 10$ V, the same value you used for the amplifier discussed in problems 34–41:

$$R_D = \frac{(V_{DD} - V_{DS} - V_S)}{I_D}$$

3. Calculate X_{CS} using the following formula:

$$X_{CS} = \frac{R_S}{10}$$

Then, calculate C_S using the following formula:

$$X_{CS} = \frac{1}{2\pi f C_S}$$

4. Calculate the peak-to-peak output voltage using the procedures shown in problems 34–36.
5. Calculate the AC voltage gain using this formula:

$$A_V = \frac{-V_{out}}{V_{in}}$$

NOTE Choose the value of C_S so that its reactance is less than 10 percent of R_S at the lowest frequency you need to amplify. The DC load for the JFET is R_D plus R_S. The AC load is R_D only, because C_S bypasses the AC signal around R_S, which keeps the DC operating point stable. The use of C_S reduces the gain slightly because you now use a smaller R_D to calculate the AC voltage swings at the output.

Questions

A. What is the value of R_S?

B. What is the value of R_D?

C. What is the value of C_S? Assume f = 1 kHz.

D. Calculate the peak-to-peak V_{out} for $V_{in} = 0.5\ V_{pp}$.

E. What is the voltage gain?

Answers

A. $R_S = \dfrac{2\,V}{3\,mA} = 667\,ohms$

B. $R_D = \dfrac{12\,V}{3\,mA} = 4\,k\Omega$

C. $X_{CS} = 66.7$ ohms, $C_S = 2.4\ \mu F$

D. The AC drain current will still vary from 3.8 to 2.3 mA, as in problem 37. The voltage across R_D is now 6 V_{pp}, because R_D is 4 kΩ. The output voltage is also 6 V_{pp}.

E. $A_V = \dfrac{-6}{0.5} = -12$ The gain is 12.

The Operational Amplifier

43 The operational amplifier (op-amp) in use today is actually an integrated circuit (IC). This means that the device has numerous transistors and other components constructed on a very small silicon chip. These IC op-amps are much smaller and, therefore, more practical than an amplifier with equivalent performance that is made with discrete components.

It is possible to purchase op-amps in different case configurations. Some of these configurations are the TO metal package, the flat pack, and the DIP package. You will also find 2 op-amps (dual) or 4 op-amps (quad) in a single IC.

Their size, low cost, and wide range of applications have made op-amps so common today that they are thought of as a circuit device or component in and of themselves, even though a typical op-amp may contain 20 or more transistors in its design. The characteristics of op-amps very closely resemble those of an ideal amplifier. Following are these characteristics:

- High input impedance (does not require input current)
- High gain (used for amplifying small signal levels)
- Low output impedance (not affected by the load)

Questions

A. What are the advantages of using op-amps?

____

B. Why are op-amps manufactured using IC techniques?

____

Answers

A. Small size, low cost, wide range of applications, high input impedance, high gain, and low output impedance.

B. Because of the large numbers of transistors and components that are required in the design of an op-amp, they must be constructed on a single, small silicon chip using IC manufacturing techniques to be of a reasonable size.

44 Figure 8-29 shows the schematic symbol for an op-amp.

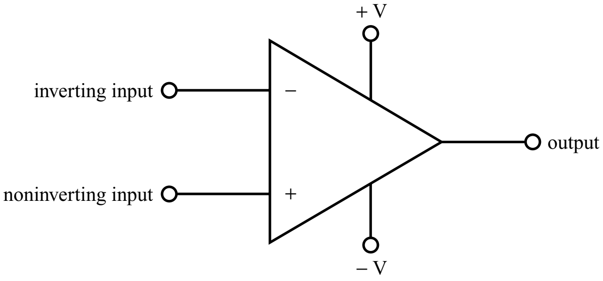

Figure 8-29

An input at the inverting input results in an output that is 180 degrees out of phase with the input. An input at the non-inverting input results in an output that is in phase with the input. Both positive and negative voltage supplies are required, and the datasheet will specify their values for the particular op-amp you are using. Datasheets usually contain circuit diagrams showing how you should connect external components to the op-amp for specific applications. These circuit diagrams (showing how a particular op-amp can be used for various applications) can be very useful to the designer or the hobbyist.

Questions

A. How many terminals does the op-amp require, and what are their functions?

B. How is the output related to the input when the input is connected to the inverting input?

Answers

A. 5 — two input terminals, one output terminal, two power supply terminals.

B. The output is 180 degrees out of phase with the input.

45 Figure 8-30 shows a basic op-amp circuit. The input signal is connected to an inverting input, as indicated by the negative sign. Therefore, the output signal will be 180 degrees out of phase with the input.

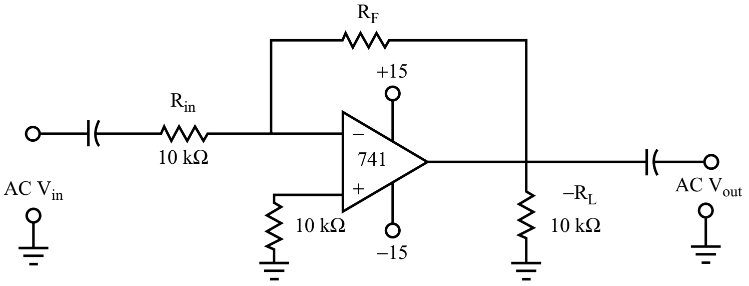

Figure 8-30

You can find the AC voltage gain for the circuit using the following equation:

$$A_v = \frac{-R_F}{R_{in}}$$

Resistor R_F is called a *feedback resistor*, because it forms a feedback path from the output to the input. Many op-amp circuits use a feedback loop. Because the op-amp has such a high gain, it is easy to saturate it (at maximum gain) with small voltage differences between the two input terminals. The feedback loop allows the operation of the op-amp at lower gains, allowing a wider range of input voltages. When designing a circuit, you can choose the value of the feedback resistor to achieve a specific voltage gain. The role of the capacitors in the diagram is to block DC voltages.

Questions

A. Calculate the value of R_F that would give the amplifier an AC voltage gain of 120.

____

B. Calculate A_C V_{out} if AC V_{in} is 5 mV_{rms}.

____

Answers

A. $R_F = 120 \times 10\,k\Omega = 1.2\,M\Omega$

B. $V_{out} = 120 \times 5\,mV = 0.6\,V_{rms}$

The output signal is inverted with respect to the input signal.

46 Use the op-amp circuit shown in Figure 8-30 to build an amplifier with an output voltage of 12 V_{pp}, an AC voltage gain of 50, and with $R_{in} = 6.8\,k\Omega$.

Questions

A. Calculate the value of R_F.

____

B. Calculate the value of V_{in} required to produce the output voltage specified earlier.

____

Answers

A. $R_F = 50 \times 6.8\,k\Omega = 340\,k\Omega$

B. $V_{in} = \dfrac{12\,V_{pp}}{50} = 0.24\,V_{pp}$ or $0.168\,V_{rms}$

Summary

This chapter introduced the most common types of amplifiers in use today: the common emitter BJT, the common source JFET, and the op-amp. At best, this chapter has only scratched the surface of the world of amplifiers. In fact, there are many variations and types of amplifiers. Still, the terminology and design approach you learned here should give you a basic foundation for further study.

Following are the key skills you gained in this chapter:

- How to design a simple amplifier when the bias point and the gain are specified
- How to do the same for an emitter follower
- How to analyze a simple amplifier circuit

Self-Test

These questions test your understanding of the material presented in this chapter. Use a separate sheet of paper for your diagrams or calculations. Compare your answers with the answers provided following the test.

1. What is the main problem with the amplifier circuit shown in Figure 8-1?

____

2. What is the gain formula for that circuit?

____

3. Does it have a high or low gain?

Use the circuit shown in Figure 8-31 for questions 4–8.

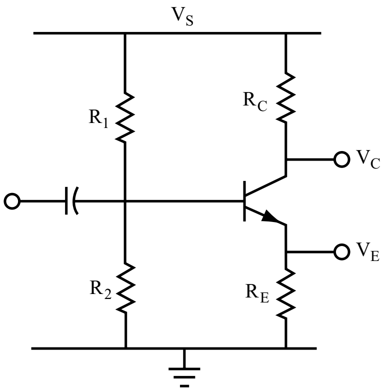

Figure 8-31

4. Design an amplifier so that the bias point is 5 V and the AC voltage gain is 15. Assume $\beta = 75$, $R_{in} = 1.5\ k\Omega$, $V_S = 10$ V, and $R_C = 2.4\ k\Omega$. Add capacitor C_E to the circuit and calculate a suitable value to maintain maximum AC voltage gain at 50 Hz. What is the approximate value of this gain?

---

5. Repeat question 4 with these values: $V_S = 28$ V, $\beta = 80$, $R_{in} = 1\ k\Omega$, and $R_C = 10\ k\Omega$. The bias point should be 14 V, and the AC voltage gain 20.

---

6. Repeat question 4 with these values: $V_S = 14$ V, $\beta = 250$, $R_{in} = 1\ k\Omega$, and $R_C = 15\ k\Omega$. The bias point should be 7 V, and the AC voltage gain 50.

---

7. Design an emitter follower amplifier given that $V_S = 12$ V, $R_E = 100$ ohms, $\beta = 35$, $V_E = 7$ V, $R_C = 0$ ohms.

---

8. Design an emitter follower amplifier given that $V_S = 28$ V, $R_E = 100$ ohms, $\beta = 35$, $V_E = 7$ V, $R_C = 0$ ohms.

In questions 9–11, the resistance and β values are given. Analyze the circuit to find the bias point and the gain.

9. $R_1 = 16\ k\Omega$, $R_2 = 2.2\ k\Omega$, $R_E = 100$ ohms, $R_C = 1\ k\Omega$, $\beta = 100$, $V_S = 10$ V

10. $R_1 = 36\ k\Omega$, $R_2 = 3.3\ k\Omega$, $R_E = 110$ ohms, $R_C = 2.2\ k\Omega$, $\beta = 50$, $V_S = 12$ V

11. $R_1 = 2.2\ k\Omega$, $R_2 = 90\ k\Omega$, $R_E = 20$ ohms, $R_C = 300\ k\Omega$, $\beta = 30$, $V_S = 50$ V

12. The circuits from questions 4 and 5 are connected to form a two-stage amplifier. What is the gain when there is an emitter bypass capacitor for both transistors? When the capacitor is not used in either of them?

13. Design a JFET amplifier using the circuit shown in Figure 8-27. The characteristics of the JFET are $I_{DSS} = 20$ mA and $V_{GS(off)} = -4.2$ V. The desired value of V_{DS} is 14 V. Find the value of R_D.

14. If the transconductance of the JFET used in question 13 is 0.0048 mhos, what is the voltage gain?

15. If the desired output is 8 V_{pp} for the JFET of questions 13 and 14, what should the input be?

16. Design a JFET amplifier using the circuit in Figure 8-28. The JFET characteristics are $I_{DSS} = 16$ mA and $V_{GS(off)} = -2.8$ V. Using a V_{DS} of 10 V, find the values of R_S, C_S, and R_D.

17. If the input to the JFET in question 16 is 20 mV_{pp}, what is the AC output voltage and what is the gain?

18. For the op-amp circuit shown in Figure 8-30, what is the output voltage if the input is 50 mV and the feedback resistor is 750 kΩ?

Answers to Self-Test

If your answers do not agree with those provided here, review the problems in parentheses before you go on to the next chapter.

1.	Its bias point is unstable, and its gain varies with temperature. Also, you cannot guarantee what the gain will be.	(problem 10)
2.	$A_V = \beta \times \frac{R_C}{R_{in}}$	(problem 10)
3.	Usually the gain is quite high.	(problem 10)
For Numbers 4–6, suitable values are given. Yours should be close to these.		
4.	$R_1 = 29$ kΩ, $R_2 = 3.82$ kΩ, $R_E = 160$ ohms, $C_E = 200$ μF, $A_V = 120$	(problems 17–22)
5.	$R_1 = 138$ kΩ, $R_2 = 8$ kΩ, $R_E =$ 500 ohms, $C_E = 64$ μF, $A_V = 800$	(problems 17–22)
6.	$R_1 = 640$ kΩ, $R_2 = 45$ kΩ, $R_E =$ 300 ohms, $C_E = 107$ μF, $A_V = 750$	(problems 17–22)
7.	$R_1 = 8$ kΩ; $R_2 = 11.2$ kΩ	(problem 27)
8.	$R_1 = 922$ ohms; $R_2 = 385$ ohms	(problem 27)
9.	$V_C = 5$ V, $A_V = 10$	(problems 28–30)
10.	$V_C = 6$ V, $A_V = 20$	(problems 28–30)
11.	$V_C = 30$ V, $A_V = 15$	(problems 28–30)
12.	When the capacitor is used, $A_V = 120 \times 800 = 96{,}000$.	(problems 17–22)
	When the capacitor is not used, $A_V = 15 \times 20 = 300$.	
13.	Use $V_{GS} = -2.1$ V, then $I_D = 5$ mA, $R_D = 2$ kΩ.	(problems 31–33)
14.	$A_v = -9.6$ mV_{pp}	(problem 39)
15.	$V_{in} = 83$ mV_{pp}	(problem 38)

16.	Use $V_{GS} = -1.4$ V, then $I_D = 4$ mA.	(problem 42)
	$R_S = 350$ ohms	
	$C_S = 4.5\ \mu F$ (assume $f = 1$ kHz)	
	$R_D = 3.15\ k\Omega$	
17.	V_{GS} varies from -1.39 to -1.41 V, I_D varies from 4.06 to 3.94 mA, V_{out} will be 400 mV_{pp}, $A_v = \frac{-400}{20} = -20$	(problem 42)
18.	$A_v = -75$, $V_{out} = 3.75$ V	(problem 45)

CHAPTER 9

Oscillators

This chapter introduces you to oscillators. An *oscillator* is a circuit that produces a continuous output signal. There are many types of oscillator circuits that are used extensively in electronic devices. Oscillators can produce a variety of different output signals, such as sine waves, square waves, or triangle waves.

When the output signal of an oscillator is a sine wave of constant frequency, the circuit is called a *sine wave oscillator*. Radio and television signals are sine waves transmitted through the air, and the 120 V AC from the wall plug is a sine wave, as are many test signals used in electronics.

This chapter introduces three basic sine wave oscillators. They all rely on resonant LC circuits as described in Chapter 7 to set the frequency of the sine wave.

When you complete this chapter, you will be able to do the following:

- Recognize the main elements of an oscillator.
- Differentiate between positive and negative feedback.
- Specify the type of feedback that causes a circuit to oscillate.
- Specify at least two methods of obtaining feedback in an oscillator circuit.
- Understand how resonant LC circuits set the frequency of an oscillator.
- Design a simple oscillator circuit.

Understanding Oscillators

1 An oscillator can be divided into three definite sections: (1) an amplifier; (2) the feedback connections; and (3) the components that set frequency.

The amplifier replaces the switch in the basic oscillator circuit, introduced in problem 35 of Chapter 7 (Figure 7-32).

Question

Draw an oscillator circuit, and label the parts. Use a separate sheet of paper for your drawing.

Answer

See Figure 9-1.

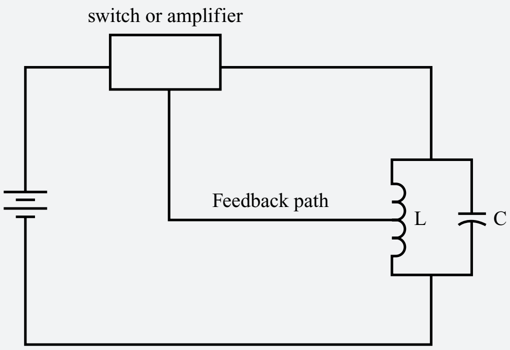

Figure 9-1

2 When you connect the output of an amplifier to its input, you get feedback. If the feedback is ‘‘out of phase’’ with the input, as shown in Figure 9-2, then the feedback is *negative*.

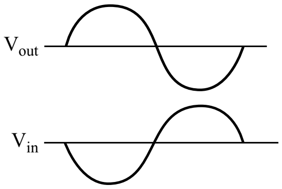

Figure 9-2

When the signal from the collector is fed back to the base of the transistor through a feedback resistor (R_f), as in the circuit shown in Figure 9-3, the feedback signal is out of phase with the input signal. Therefore, the feedback is negative.

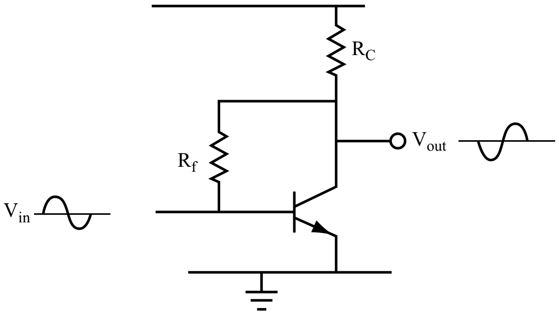

Figure 9-3

Negative feedback is used to stabilize the operation of an amplifier by doing the following:

- Preventing the DC bias point and gain of an amplifier from being affected by changes in temperature
- Reducing distortion in amplifiers, thereby improving the quality of the sound

Questions

A. Why would feedback signals be used in quality audio amplifiers?

____

B. What kind of feedback do they have?

____

Answers

A. To reduce distortion

B. Negative feedback

3 If the feedback from the output is in phase with the input, as shown in Figure 9-4, the circuit's feedback is *positive*.

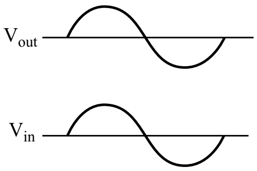

Figure 9-4

In the circuit shown in Figure 9-5, the collector of the second transistor is connected to the base of the first transistor. Because the output signal at the collector of the second transistor is in phase with the input signal at the base of the first transistor, this circuit has positive feedback.

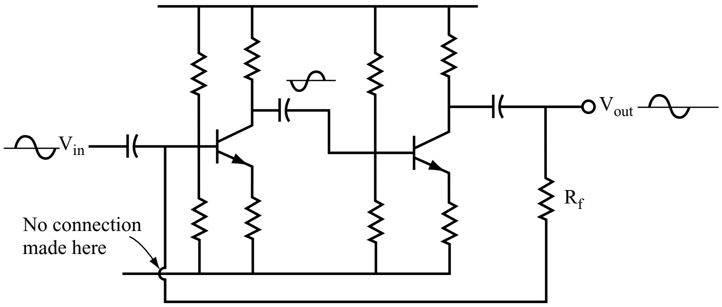

Figure 9-5

Positive feedback can cause an amplifier to oscillate even when there is *no external input*.

Questions

A. What type of feedback is used to stabilize an amplifier?

____

B. What type of feedback is used in oscillators?

____

C. What parts of an amplifier do you connect to produce feedback?

____

Answers

A. Negative feedback

B. Positive feedback

C. Connect the output of an amplifier to its input.

4 The amplifier shown in Figure 9-6 is the same type of amplifier that was discussed in problems 11–18 of Chapter 8. It is called a *common emitter amplifier*.

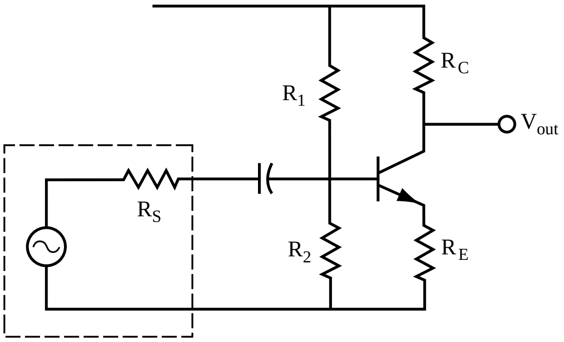

Figure 9-6

Questions

A. What effect would negative feedback have on this amplifier?

____

B. What effect would positive feedback have on this amplifier?

____

Answers

A. Stabilize it, reduce gain, and reduce distortion.

B. Cause it to oscillate.

5 In the circuit shown in Figure 9-6, an input signal that is applied to the base will be amplified.

Questions

A. What is the basic formula for an amplifier's voltage gain?

____

B. What is the voltage gain formula for the amplifier circuit shown in Figure 9-6?

____

Answers

A. $A_V = \beta \times \dfrac{R_L}{R_{in}}$

B. $A_V = \dfrac{R_L}{R_E} = \dfrac{R_C}{R_E}$

(as discussed in problem 12 of Chapter 8)

6 In the circuit shown in Figure 9-7, an input signal is applied to the emitter of the transistor instead of the base. This circuit is called a *common base amplifier*.

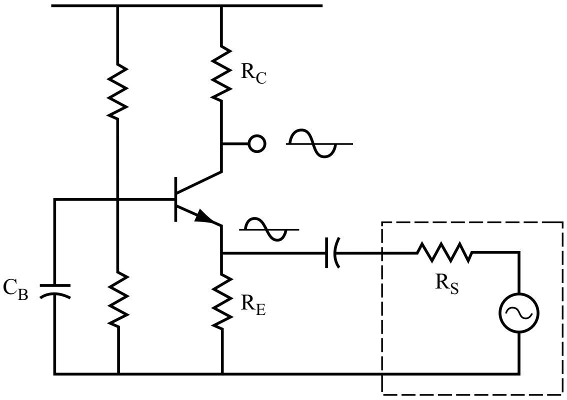

Figure 9-7

NOTE When you apply a signal to the emitter, it changes the voltage drop across the base-emitter diode, just as an input signal applied to the base does. Therefore, a signal applied to the emitter changes the base current and the collector current, just as if you had applied a signal to the base.

The voltage gain formula for this type of amplifier can be simplified because the input impedance to the amplifier is so low when the signal is fed into the emitter that you can discount it. This results in the following voltage gain formula for the common base amplifier:

$$A_V = \frac{R_L}{R_S}$$

R_S is the output resistance or impedance of the source or generator. It is also called the *internal impedance* of the source.

Question

What is the voltage gain formula for the circuit shown in Figure 9-7?

Answer

$A_V = \frac{R_L}{R_S} = \frac{R_C}{R_S}$, ($R_C$ is the load in this circuit)

7 Notice that the input and output sine waves in Figure 9-7 are in phase. Although the signal is amplified, it is not inverted.

Questions

A. What happens to the input signal to the amplifier when you apply it to the emitter instead of the base?

B. Is the input impedance of the common base amplifier high or low compared to the common emitter amplifier?

C. What is the gain formula for the common base amplifier?

Answers

A. Amplified and not inverted

B. Low

C. $A_V = \frac{R_L}{R_S} = \frac{R_C}{R_S}$

8 Figure 9-8 shows an amplifier circuit with a parallel inductor and capacitor connected between the collector of the transistor and ground. A parallel inductor and capacitor circuit is sometimes called a *tuned* (or *resonant*) *load*.

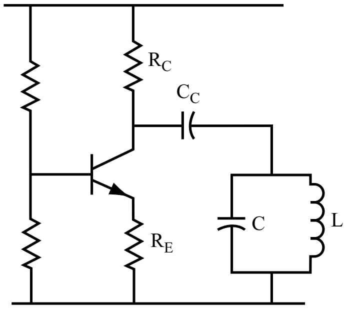

Figure 9-8

In this circuit, the inductor has a very small DC resistance, which could pull the collector DC voltage down to near 0 V. Therefore, you include capacitor C_C in the circuit to allow AC signals to pass through the LC circuit while preventing the collector DC voltage from being pulled down to 0 V.

Questions

A. What term would you use to describe the load in this circuit?

____

B. Does the circuit contain all three components of an oscillator at this point?

____

Answers

A. Resonant or tuned

B. No, the feedback connections are missing.

NOTE **The circuit in Figure 9-8 does not have an input signal either to the emitter or to the base. By adding a feedback connection to a parallel LC circuit, you provide an input signal to the emitter or base, as explained later in this chapter.**

9 Write the voltage gain formulas for the following circuits. Refer to the circuits and voltage gain formulas in problems 4–6, if necessary.

Questions

A. Common emitter circuit____________________________

B. Common base circuit____________________________

Answers

A. $A_V = \dfrac{R_C}{R_E}$

B. $A_V = \dfrac{R_C}{R_S}$

10 You can use common emitter and common base amplifier circuits in oscillators, and in each case, you would usually also include an extra capacitor.

In a common emitter amplifier, you can add a capacitor (C_E) between the emitter and ground, as discussed in problems 19 and 20 of Chapter 8.

In a common base circuit, you can add a capacitor (C_B) between the base and the ground, as is shown in Figure 9-7.

Question

What is the general effect in both cases?

____

Answer

An increase in the gain of the amplifier.

The gain is increased to the point where you can consider it ''large enough'' to use the amplifier as an oscillator. When these capacitors are used in either a common emitter or common base amplifier, it is not usually necessary to calculate the gain of the amplifier.

11 An LC circuit has a resonance frequency that you can determine using the methods discussed in problems 6–12 of Chapter 7. When you use an LC circuit in an oscillator, the output signal of the oscillator will be at the resonance frequency of the LC circuit.

Question

What is the formula for the oscillation (or resonant) frequency?

____

Answer

$$f_r = \frac{1}{2\pi\sqrt{LC}}$$

In practice, the actual measured frequency is never quite the same as the calculated frequency. The capacitor and inductor values are not exact, and other stray capacitances in the circuit affect the frequency. When you need to set an exact frequency, use an adjustable capacitor or inductor.

12 Figure 9-9 shows the parallel LC circuit connected between the collector and the supply voltage, rather than between the collector and ground (as in Figure 9-8).

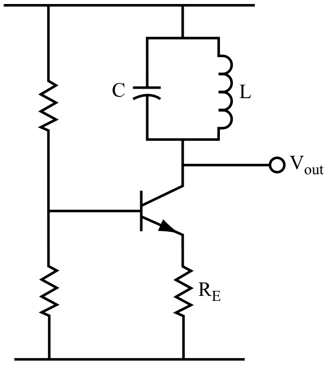

Figure 9-9

You can use this circuit and the circuit shown in Figure 9-8 to selectively amplify one frequency far more than others.

Questions

A. What would you expect this one frequency to be?

____

B. Write the formula for the impedance of the circuit at the resonance frequency.

____

C. What is the AC voltage gain at this frequency?

____

Answers

A. The resonance frequency

B. $Z = \frac{L}{C \times r}$

where r is the DC resistance of the coil

C. $A_V = \frac{Z}{R_E}$

13 Because of the very low DC resistance of the coil, the DC voltage at the collector is usually very close to the supply voltage (V_S). In addition, the AC output voltage positive peaks can exceed the DC level of the supply voltage. With large AC output, the positive peaks can actually reach $2V_S$, as shown in Figure 9-10.

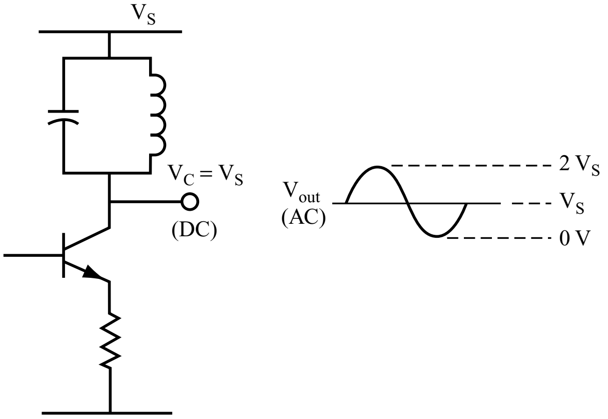

Figure 9-10

Question

Indicate which of the following is an accurate description of the circuit in Figure 9-10:

A. Oscillator

B. Tuned amplifier

C. Common base circuit

D. Common emitter circuit

Answer

B

Feedback

14 To convert an amplifier into an oscillator, you must connect a portion of the output signal to the input. This feedback signal must be in phase with the input signal to induce oscillations.

Figure 9-11 shows three methods you can use to provide a feedback signal from a parallel LC circuit. Each is named for its inventor.

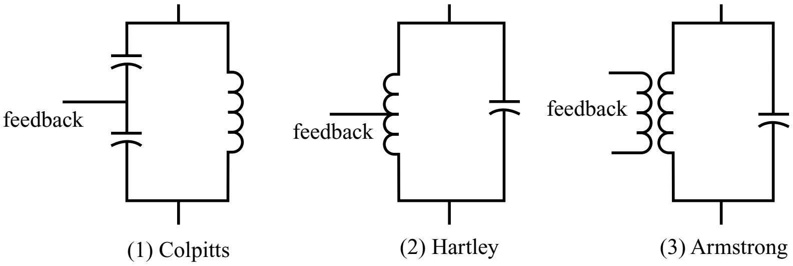

Figure 9-11

In the *Colpitts* method, the feedback signal is taken from a connection between two capacitors that form a voltage divider. In the *Hartley* method, the feedback signal is taken from a tap partway down the coil. Therefore, an inductive voltage divider determines the feedback voltage. The *Armstrong* method uses a step down transformer (an inductor with an extra coil with fewer turns than the main coil). In all three of these methods, between one-tenth and a half of the output must be used as feedback.

Questions

A. Where is the feedback taken from in a Colpitts oscillator?

B. What type of oscillator uses a tap on the coil for the feedback voltage?

C. What type does not use a voltage divider?

____

Answers

A. A capacitive voltage divider

B. Hartley

C. Armstrong

15 The output voltage appears at one end of the parallel LC circuit shown in Figure 9-12, and the other end is effectively at ground. The feedback voltage V_f is taken between the junction of the two capacitors.

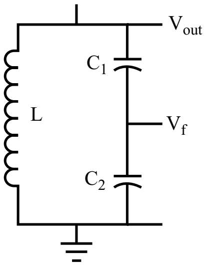

Figure 9-12

Question

Using the voltage divider formula, what is V_f?

____

Answer

$$V_f = \frac{V_{out}X_{C2}}{(X_{C1} + X_{C2})}$$

which becomes

$$V_f = \frac{V_{out}C_1}{(C_1 + C_2)}$$

16 To find the resonance frequency in this circuit, first find the equivalent total capacitance C_T of the two series capacitors. You then use C_T in the resonance frequency formula.

Questions

A. What is the formula for C_T?

____

B. What is the resonance frequency formula for the Colpitts oscillator?

____

Answers

A. $C_T = \frac{C_1 C_2}{C_1 + C_2}$

B. $f_r = \frac{1}{2\pi\sqrt{LC_T}}$,
if Q is equal to or greater than 10

NOTE **If Q is less than 10, you can use one of the following two formulas to calculate the resonance frequency for a parallel LC circuit:**

$$f_r = \frac{1}{2\pi\sqrt{LC}}\sqrt{1 - \frac{r^2C}{L}} \text{ or } f_r = \frac{1}{2\pi\sqrt{LC}}\sqrt{\frac{Q^2}{1+Q^2}}$$

17 Figure 9-13 shows a parallel LC circuit in which the feedback voltage is taken from a tap N_1 turns from one end of a coil, and N_2 turns from the other end.

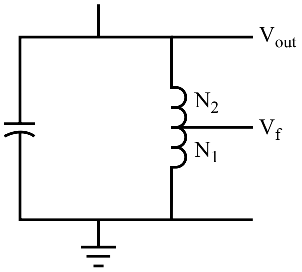

Figure 9-13

You can calculate the feedback voltage with a voltage divider formula that uses the number of turns in each part of the coil.

$$V_f = V_{out} \times \frac{N_1}{N_1 + N_2}$$

The manufacturer should specify N_1 and N_2.

Questions

A. Who invented this feedback method?

____

B. When you divide V_f by V_{out}, what should the result be?

____

Answers

A. Hartley

B. Between one-tenth and one-half

18 Figure 9-14 shows a parallel LC circuit in which the feedback voltage is taken from the secondary coil of a transformer. The formula used to calculate the output voltage of a secondary coil is covered in problem 6 of Chapter 10.

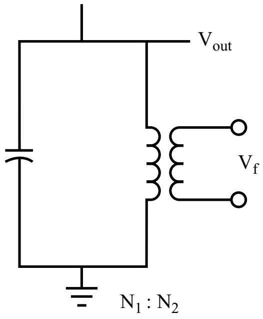

Figure 9-14

Question

Who invented this type of oscillator?

____

Answer

Armstrong

19 For each of the feedback methods described in the last few problems, the voltage fed back from the output to the input is a fraction of the total output voltage ranging between one-tenth and one-half of V_{out}.

To ensure oscillations, the product of the feedback voltage and the amplifier voltage gain must be greater than 1.

$A_V \times V_f > 1$

It is usually easy to achieve this because A_v is much greater than 1.

No external input is applied to the oscillator. Its input is the small part of the output signal that is fed back. If this feedback is of the correct phase and amplitude, the oscillations start spontaneously and continue as long as power is supplied to the circuit.

The transistor amplifier amplifies the feedback signal to sustain the oscillations, and converts the DC power from the battery or power supply into the AC power of the oscillations.

Questions

A. What makes an amplifier into an oscillator?

____

B. What input does an amplifier need to become an oscillator?

____

Answers

A. A resonant LC circuit with feedback of the correct phase and amount

B. None. Oscillations will happen spontaneously if the feedback is correct.

The Colpitts Oscillator

20 Figure 9-15 shows a Colpitts oscillator circuit, the simplest of the LC oscillators to build.

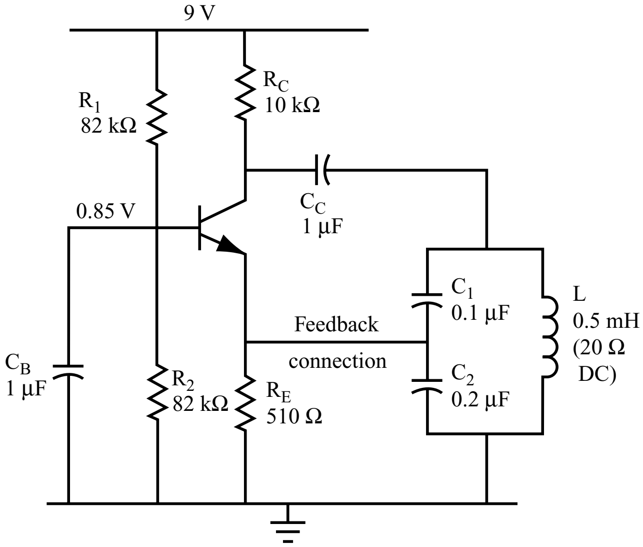

Figure 9-15

The feedback signal is taken from the capacitive voltage divider and fed to the emitter. This connection provides a feedback signal to the emitter in the phase required to provide positive feedback.

In this circuit, the reactance of capacitor C_B is low enough for the AC signal to pass through it, rather than passing through R_2. Capacitor C_E should have a reactance, X_{CB}, of less than 160 ohms at the oscillation frequency. If R_2 happens to be smaller than 1.6 kΩ, choose a value of X_{CB} that is less than one-tenth of R2.

Question

For the circuit shown in Figure 9-15, what is your first estimate for C_B? Assume that f_r is equal to 1 kHz and that X_c equals 160 ohms.

Answer

$$X_{CB} = 160\,\text{ohms} = \frac{1}{2\pi f C_B} = \frac{1}{2 \times \pi \times 10^3 \times C_B}$$

Therefore, $C_B = 1\ \mu F$; larger values of C_B also work.

21 Use the Colpitts oscillator component values shown in Figure 9-15 to answer the following questions.

Questions

A. What is the effective total capacitance of the two series capacitors in the tuned circuit?

C_T = ______________________________

B. What is the oscillator frequency?

f_r = ______________________________

C. What is the impedance of the tuned circuit at this frequency?

Z = ______________________________

D. What fraction of the output voltage is fed back?

V_f = ______________________________

E. What is the reactance of C_B at the frequency of oscillation?

X_{CB} = ______________________________

Answers

A. $C_T = 0.067\ \mu F$

B. Because Q is not known, use the formula that includes the resistance of the coil (see problem 16):

$f_r = 26.75$ kHz

If you use the calculated value of f_r to calculate Q, as in problem 20 of Chapter 8, you find that $Q = 4.2$. Therefore, it is appropriate to use the formula that includes the resistance of the coil to calculate f_r.

C. Using

$$Z_T = \frac{L}{rC},\ Z_T = 373 \text{ ohms}.$$

D. Using a voltage divider with the capacitor values,

$$V_f = V_{out}\frac{C_1}{(C_1 + C_2)} = \frac{V_{out}}{3}.$$

E. X_{CB} = about 6 ohms, which is a very good value (much less than the 8200 ohm value of R_2)

22 Figure 9-16 shows a Colpitts oscillator circuit that uses a different method for making feedback connections between the parallel LC circuit and the transistor.

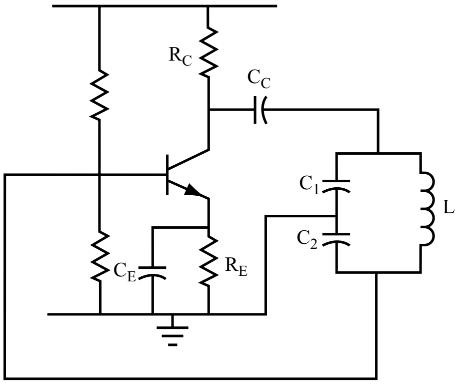

Figure 9-16

Question

List the differences between this circuit and the one shown in Figure 9-15.

Answer

The feedback is connected to the base instead of the emitter, and the ground is connected to the center of the capacitive voltage divider. The capacitor C_E has been added. (This connection provides a feedback signal to the base in the correct phase to provide positive feedback.)

23 In the circuit shown in Figure 9-16, capacitor C_E should have a reactance of less than 160 ohms at the oscillation frequency. If the emitter resistor R_E is smaller in value than 1.6 kΩ, then C_E should have a reactance that is less than $R_E/10$ at the oscillation frequency.

Question

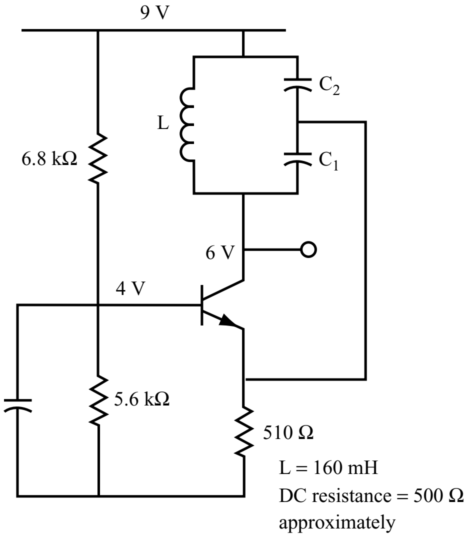
If you use an emitter resistor of 510 ohms in a 1 kHz oscillator, what value of capacitor should you use for C_E?

Answer

$$X_C = \frac{510}{10} = \frac{1}{2\pi f C_E} = \frac{0.16}{10^3 \times C_E}$$

So, $C_E = 3.2\ \mu F$. Thus, you should use a capacitor larger than 3 μF.

24 Figure 9-17 shows a Colpitts oscillator with the parallel LC circuit connected between the collector and the supply voltage. As with the circuits shown in Figures 9-15 and 9-16, this circuit provides a feedback signal to the transistor (in this case, the emitter) in the correct phase to provide positive feedback.



L = 160 mH
DC resistance = 500 Ω approximately

Figure 9-17

The following table shows possible values you might use for C_1 and C_2 in the circuit shown in Figure 9-17.

C_1	C_2	C_T	F_R
0.01 µF	0.1 µF		
0.01 µF	0.2 µF		
0.01 µF	0.3 µF		
0.1 µF	1 µF		
0.2 µF	1 µF		

Questions

A. Calculate C_T and f_r for each row of the preceding table.

B. Does increasing C_2 while holding C_1 constant increase or decrease the resonance frequency?

____

C. What effect does increasing C_1 have on the resonance frequency?

____

D. What is the condition that results in the highest possible resonance frequency?

____

E. What would be the highest resonance frequency if C_1 is fixed at 0.01 μF and C_2 can vary from 0.005 μF to 0.5 μF?

____

Answers

A. The values of C_T and f_r are shown in the following table.

C_1	C_2	C_T	F_R
0.01 μF	0.1 μF	0.009 μF	4.19 kHz
0.01 μF	0.2 μF	0.0095 μF	4.08 kHz
0.01 μF	0.3 μF	0.0097 μF	4.04 kHz
0.1 μF	1 μF	0.09 μF	1.33 kHz
0.2 μF	1 μF	0.167 μF	0.97 kHz

B. Increasing C_2 decreases the resonance frequency, and, therefore, decreases the output frequency of the oscillator.

C. Increasing C_1 will also decrease the resonance frequency and the output frequency of the oscillator.

D. When C_T is at its lowest possible value.

E. When C_2 is 0.005 μF, C_T will be 0.0033 μF, which is its lowest possible value. Therefore, the frequency is at the highest possible value, or about 6.9 kHz. The lowest frequency occurs when C_2 is at its highest setting of 0.5 μF.

Optional Experiment

If you have an oscilloscope, you may want to build the oscillator shown in Figure 9-17 and see how closely your measurements of the frequency agree with those you have just calculated. If you are within 20 percent, then the answers are satisfactory. In some cases, the waveform may be distorted.

The Hartley Oscillator

25 Figure 9-18 shows a Hartley oscillator circuit. In this type of circuit, the feedback is taken from a tap on the coil.

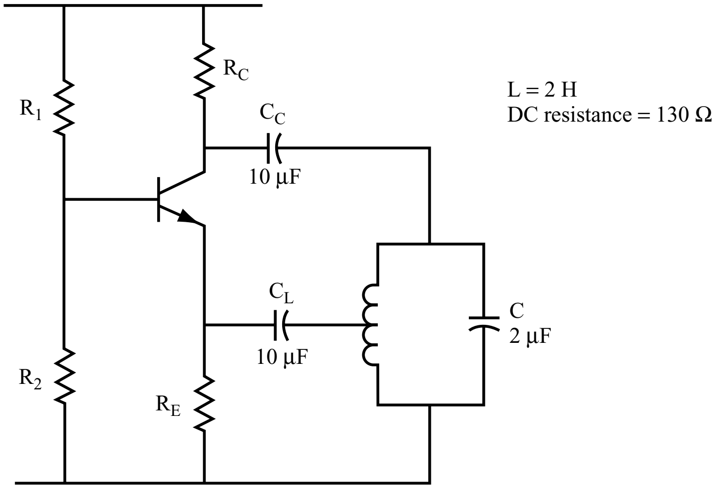


Figure 9-18

Capacitor C_L stops the emitter DC voltage from being pulled down to 0 V through the coil. C_L should have a reactance of less than $R_E/10$, or less than 160 ohms at the oscillator frequency.

Questions

Work through the following calculations:

A. What is the resonance frequency?

f_r = ____________________

B. What is the approximate impedance of the load?

Z = ____________________

C. What missing information prevents you from calculating the fraction of the voltage drop across the coil that is fed back to the emitter?

____

Answers

A. 80 Hz (approximately)

B. 7.7 kΩ (approximately)

C. The number of turns in the coil and the position of the tap are not known.

Figure 9-19 shows a Hartley oscillator with the parallel LC circuit connected between the collector and the supply voltage. As with the circuit shown in Figure 9-18, this circuit provides a feedback signal to the emitter from a tap in the coil, in the correct phase to provide positive feedback.

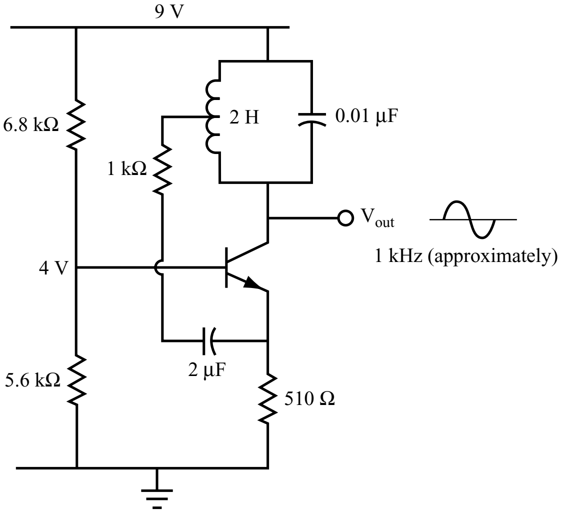

Figure 9-19

For a Colpitts oscillator it is easy to choose the two capacitors to provide both the desired frequency and the desired amount of feedback. If the circuit does not oscillate, it is relatively simple to change the capacitors until it does oscillate, and then adjust the values slightly to get the desired frequency.

Because a Hartley oscillator uses a tapped coil, trying out different feedback voltages is not quite so easy. The feedback ratio cannot be altered, because it is impossible to make another tap or change the tap on the coil.

The Armstrong Oscillator

The Armstrong oscillator shown in Figure 9-20 is somewhat more difficult to design and build.

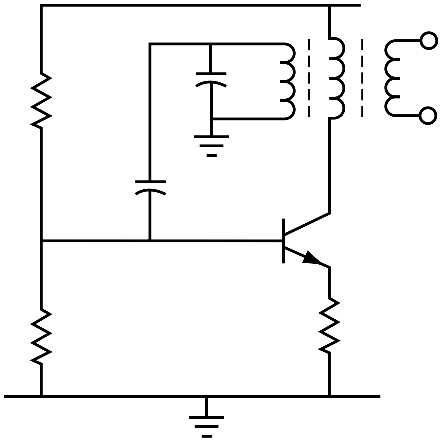

Figure 9-20

Here, the oscillations depend more on the extra winding on the coil than on any other factor.

Because of the large variety of transformers and coils available, it is almost impossible to give you a simple procedure for designing an Armstrong oscillator. Instead, the manufacturer specifies the number of turns required on the coils, which guarantees that the oscillator will work in its most common operation, at high radio frequencies.

Because of the practical difficulties, the Armstrong and its variations are not explored any further.

Practical Oscillator Design

26 This section briefly covers some practical problems with oscillators, and then presents a simple design procedure.

Before you proceed, review the important points of this chapter by answering the following questions.

Questions

A. What three elements must an oscillator have present to work?

____

B. What determines the frequency of an oscillator's output signal?

____

C. What provides the feedback?

____

D. How many feedback methods for oscillators have we presented?

____

E. What do you need to start the oscillations once the circuit has been built?

____

Answers

A. An amplifier, a resonant LC circuit (or some other frequency determining components), and feedback.

B. The frequency of the output signal is the same as the resonance frequency.

C. A voltage divider on the resonant circuit.

D. Three — the Colpitts, Hartley, and the Armstrong.

E. Nothing — the oscillations should start spontaneously if the component values in the circuit are correct.

The main practical problem in building oscillators is selecting the coil. For mass production, a manufacturer can specify and purchase the exact coil required. But in a lab or workshop, where you are building only a single circuit, it is often difficult or impossible to find the exact inductor specified in a circuit design. What usually happens is that you use the most readily available coil, and design the rest of the circuit around it. This presents three possible problems:

- You may not know the exact value of the inductance.
- The inductance value may not be the best for the desired frequency range.
- The coil may or may not have tap points or extra windings, and this may cause a change in the circuit design. For example, if there are no taps, then you cannot build a Hartley oscillator.

Because Colpitts is the easiest oscillator to make work in practice and provides an easy way around some of the practical difficulties, let's focus on that oscillator.

You can use almost any coil when building a Colpitts oscillator, provided it is suitable for the frequency range you want. For example, a coil from the tuner section of a television set would not be suitable for a 1 kHz audio oscillator because its inductance value is outside the range best suited to a low frequency audio circuit.

Simple Oscillator Design Procedure

27 Following is a simple step-by-step procedure for the design of a Colpitts oscillator. The Colpitts will work over a wide frequency range. (A Hartley can be built from a very similar set of steps.)

By following this procedure, you can build an oscillator that works in the majority of cases. There is a procedure you can use that guarantees that the oscillator will work, but it is far more complex.

If you are not actually building the oscillator, use the assumed values provided here, and draw the circuits using your calculated values.

Follow these steps:

1. Choose the frequency of the oscillator output signal.
2. Choose a suitable coil. This step presents the greatest practical difficulty. Some values of coil are often not available, so you must use whatever is readily available. Fortunately, you can use a wide range of inductance values and still obtain the desired resonance frequency by adjusting the value of the capacitor.
3. If you know the value of the inductance, calculate the capacitor value using this formula:

   $$f_r = \frac{1}{2\pi\sqrt{LC}}$$

   Use this value of capacitor for C_1 in the next steps.
4. If you don't know the inductance value, choose any value of capacitance and call this C_1. This may produce a frequency considerably different from what you require. However, at this stage, the main thing is to get the circuit oscillating. You can adjust values later.
5. Choose a capacitor C_2 that is between 3 and 10 times the value of C_1. Figure 9-21 shows the two capacitors and the coil connected in a parallel circuit with the two capacitors acting as a voltage divider.

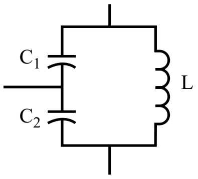

Figure 9-21

At this point, stop and make some assumptions. Suppose you need a frequency of 10 kHz and have a coil with a 16 mH inductance.

Questions

A. What approximate value of C_1 do you need?

____

B. What value of C_2 do you need?

____

Answers

A. $C_1 = 0.016\ \mu F$

B. $C_2 = 0.048\ \mu F$ to $0.16\ \mu F$

28 Now, continue with the design procedure by following the next steps.

6. Design an amplifier with a common emitter gain of about 20. Choose a collector DC voltage that is about half the supply voltage. The main point to keep in mind here is that the collector resistor R_C should be about one-tenth the value of the impedance of the LC circuit at the resonance frequency. This is often a difficult choice to make, especially if you don't know the coil value. Usually, you have to make an assumption, so R_C is an arbitrary choice.
7. Assemble the circuit shown in Figure 9-15.
8. Calculate the value of C_C. Do this by making X_C 160 ohms at the desired frequency. This is another ''rule of thumb'' that happens to work, and you can justify it mathematically. Use the following formula:

$$C_C = \frac{1}{2\pi f_r X_C}$$

Question

Substitute the values given so far into the formula to calculate C_C.

____

Answer

$$C_C = \frac{1}{2\pi \times 10\ \text{kHz} \times 160\ \Omega} = 0.1\ \mu F$$

29 Now, complete one last step.

9. Calculate the value of C_B. Again, choose a value so that X_C is 160 ohms at the desired frequency.

Question

What is the value of C_B?

Answer

$C_B = 0.1\,\mu F$

30 Continue the design procedure steps.

10. Apply power to the circuit and look at the output signal on an oscilloscope. If the output signal is oscillating, check the frequency. If the frequency varies significantly from the desired frequency, then change C_1 until you get the desired frequency. Change C_2 to keep the ratio of the capacitance values about the same as discussed in step 5. C_2 will affect the output level.
11. If the circuit does not oscillate, go through the steps outlined in the troubleshooting checklist that follows.

Optional Experiment

Once the oscillator is working, if you want to take it further, you can change the circuit to connect the feedback signal to the base instead of the emitter, as shown in Figure 9-16. To build this oscillator, you also need to calculate C_E. Assume that X_C is 160 ohms at the desired frequency.

Oscillator Troubleshooting Checklist

If an oscillator does not work, most often the trouble is with the feedback connections. A little experimenting (as outlined in steps 2 to 6 of the following checklist) should produce the right results. This is especially true when you use an unknown coil that may have several taps or windings. However, you should try each of the following steps if you're having trouble.

1. Ensure that C_B, C_C, and C_E are all large enough to have a reactance value less than 160 ohms. Ensure that C_E is less than one-tenth of R_E.

2. Check the C_1/C_2 ratio. It should be between 3:1 and 10:1.
3. Swap out C_1 and C_2. They may be connected to the wrong end of the LC circuit.
4. Check that you made the feedback connection to and from the correct place.
5. Check both ends of the LC circuit to see that they are connected to the correct place.
6. Check the DC voltage level of the collector, base, and emitter.
7. Check the capacitor values of the LC circuit. If necessary, try some other values until the circuit oscillates.
8. If none of the previous actions produce oscillations, check to see if any of the components are defective. The coil may be opened or shorted. The capacitor may be shorted. The transistor may be dead, or its β may be too low. Check the circuit wiring carefully.

In most cases, one or more of these steps produces oscillations.

When an oscillator is working it may still have one or two main faults, including the following:

- *A distorted output waveform* — This can happen when C_B, C_C, or C_E are not low enough in value, or when an output amplitude is too high.
- *Output level too low* — When this happens, the sine wave is usually very ''clean'' and ''pure.'' In a Colpitts oscillator, changing the ratio of C_1 and C_2 often helps raise the output level. If not, you can use another transistor as an amplifier after the oscillator as discussed in Chapter 8, problem 21.

31 Now, work through a design example. Design and build an oscillator with an output frequency of 25 kHz using a coil with a value of 4 mH, and address each of the steps in problems 27–30 as described in these questions.

Questions

1. The value of f_r is given as 25 kHz.
2. L is given as 4 mH.
3. Use the formula to find C_1.

   C_1 = ____________________
4. You do not need this step.
5. Choose C_2.

   C_2 = ____________________
6. The procedure to design amplifiers is shown in Chapter 8.
7. The circuit is shown in Figure 9-22.

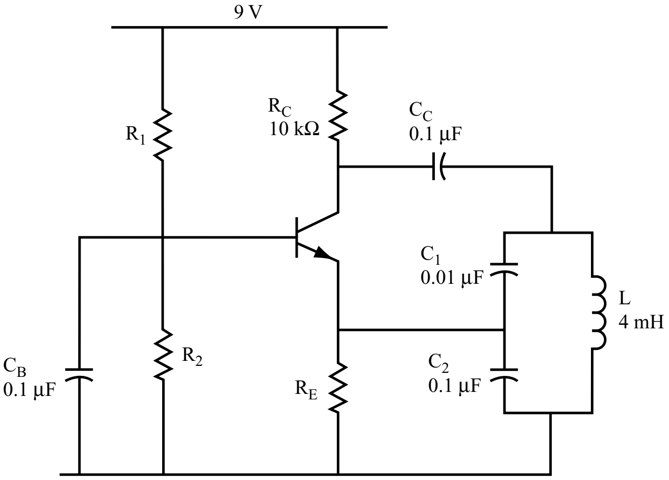

Figure 9-22

8. Find C_C.

C_C = ____________________

9. Find C_B.

C_B = ____________________

Answers

$C_1 = 0.01\ \mu F$
$C_2 = 0.1\ \mu F$
$C_C = 0.047\ \mu F$ (use $0.1\ \mu F$)
$C_B = 0.047\ \mu F$ (use $0.1\ \mu F$)

Steps 10–11 are the procedure you use to ensure that the oscillator works. If you build this circuit, go through steps 10–11. You don't need to do them if you didn't actually build the circuit.

32 Figure 9-22 shows the circuit designed in problem 31.

Measurements of the output signal of this oscillator confirm a frequency very close to 25 kHz.

Question

Find the impedance of the LC circuit at resonance. Note that r (the DC resistance of the inductor) is 12 ohms.

____

Answer

$$Z = \frac{L}{C \times r} = \frac{4 \times 10^{-3}}{0.01 \times 10^{-6} \times 12} = 33\,\text{k}\Omega \text{ (approximately)}$$

Note that this is about three times the value used for R_C instead of being 10 times the value of R_C, as suggested in step 6 of problem 28.

33 If you wish, work through this second oscillator design example. Design an oscillator with an output frequency of 250 kHz using a coil with a value of 500 μH.

Questions

1. $f_r = 250$ kHz
2. $L = 500\ \mu H = 0.5$ mH
3. Find C_1.
   $C_1 =$ ____________________
4. You do not need this step.
5. Find C_2.
   $C_2 =$ ____________________
6. Use the same amplifier as in the last example.
7. The circuit is shown in Figure 9-23.
8. Find C_C.
   $C_C =$ ____________________
9. Find C_B.
   $C_B =$ ____________________

Answers

$C_1 = 0.0008\ \mu F$; therefore, choose a standard value of 0.001 μF
$C_2 = 0.0047\ \mu F$, which is a standard value
$C_B = C_C = 0.004\ \mu F$ (minimum)

34 The circuit you designed in problem 33 is shown in Figure 9-23.

Measurements of the output signal of this oscillator confirm a frequency close to 250 kHz.

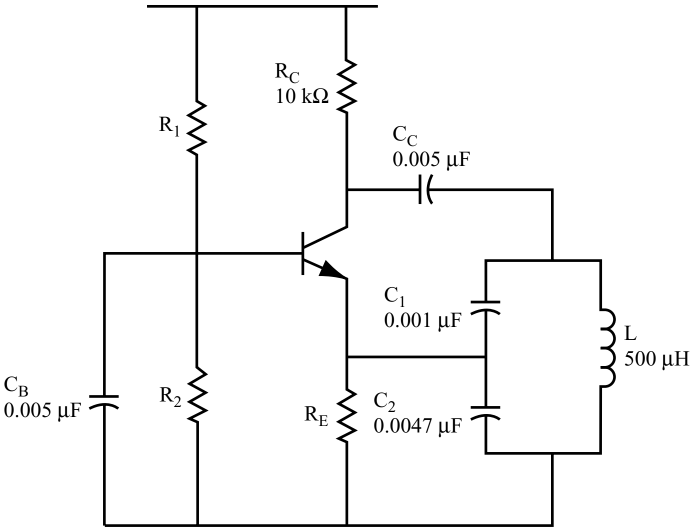

Figure 9-23

Question

Find the impedance of the LC circuit at resonance. Note that r (the DC resistance of the inductor) is 20 ohms.

Answer

Z = 30 kΩ

This is about 3 times the value of R$_C$ rather than 10 times the value of R$_C$, as suggested in step 6 of problem 28.

35 Figure 9-24 shows several other oscillator circuits. Calculate the expected output frequency for each circuit and build as many as you want to. Check the measured oscillator output frequency against the calculated values for each circuit you build.

Questions

What is the output frequency for each circuit?

A. f =

B. f =

C. f =

Summary and Applications

In this chapter, we covered the following topics related to oscillators:

- The main elements that make up an oscillator.
- How to differentiate between positive and negative feedback.
- The type of feedback that causes a circuit to oscillate.
- Two methods of obtaining feedback in an oscillator circuit.
- How resonant LC circuits set the frequency of an oscillator.

You also practiced designing a simple oscillator circuit to solidify your understanding of its elements and operation.

Self-Test

These questions test your understanding of the concepts and equations presented in this chapter. Use a separate sheet of paper for your diagrams or calculations. Compare your answers with the answers provided following the test.

1. What are the three sections that are necessary in an oscillator?

   ____

2. What is the difference between positive and negative feedback?

   ____

3. What type of feedback is required in an oscillator?

   ____

4. What is the formula for the frequency of an oscillator?

   ____

5. Draw the circuit for a Colpitts oscillator.
6. Draw the circuit for a Hartley oscillator.
7. Draw the circuit for an Armstrong oscillator.
8. Problems 27–30 give a design procedure for oscillators. How well do the circuits in problem 35 fulfill the criteria for that procedure? In other words, check the values of V_f, A_V (for a common emitter amplifier), C_1/C_2 ratio, R_C/Z ratio, and the frequency.

   A. ______________________________

   B. ______________________________

   C. ______________________________

   D. ______________________________

9. For the circuit shown in Figure 9-23, calculate the values of C_1, C_2, C_C, and C_B for an oscillator with an output frequency of 10 kHz using a 100 mH coil.

Answers to Self-Test

If your answers do not agree with those provided here, review the problems indicated in parentheses before you go on to the next chapter.

1.		An amplifier, feedback, and a resonant load	(problem 1)
2.		Positive feedback is "in phase" with the input, and negative feedback is "out of phase" with the input.	(problems 2–3)
3.		Positive feedback	(problem 3)
4.		$f_r = \frac{1}{2\pi\sqrt{LC}}$	(problem 11)
5.		See Figure 9-15.	(problem 20)
6.		See Figure 9-18.	(problem 25)
7.		See Figure 9-20.	(problem 25)
8.	A.	$V_f = \frac{0.047}{0.147}$	(problems 27–30)
		A_V cannot be calculated.	
		$C_1/C_2 = 0.047/0.1 = 0.47$	
		Z cannot be calculated because r is unknown.	
		$f_r = 8.8$ kHz (approximately)	
	B.	$V_f = \frac{0.15}{0.62}$	
		$A_V = 2.2$ (approximately)	
		$C_1/C_2 = 1/3$ (approximately)	
		Z cannot be calculated.	
		$f_r = 10$ kHz (approximately)	
	C.	$V_f = \frac{0.1}{0.2}$	
		A_v cannot be calculated.	
		$C_1/C_2 = 1$	
		Z cannot be calculated.	
		$f_r = 3$ kHz	
	D.	$V_f = \frac{0.3}{1}$	
		A_v cannot be calculated.	
		$C_1/C_2 = 0.3$	
		Z cannot be calculated.	
		$f_r = 1$ kHz (approximately)	
9.		$C_1 = 0.0033\ \mu F$; $C_2 = 0.01\ \mu F$; $C_B = C_C = 0.1\ \mu F$	(problems 26–30)

CHAPTER 10

The Transformer

Transformers are used to ''transform'' an AC voltage to a higher or lower level. When you charge up your cellphone, you are using a transformer to reduce the 120 volts supplied by the wall outlet to the 5 volts or so needed to charge your cellphone's battery. In fact, most electrical devices that you plug into wall outlets use transformers to reduce power coming from an outlet to that required by the electrical components in the device.

You can also use transformers to increase voltage. For example, some of the equipment used to manufacture integrated circuits requires thousands of volts to operate. Transformers are used to increase the 240 volts supplied by the power company to the required voltage.

When you complete this chapter, you will be able to do the following:

- Recognize a transformer in a circuit.
- Explain and correctly apply the concepts of *turns ratio* and *impedance matching*.
- Recognize two types of transformer.
- Do simple calculations involving transformers.

Transformer Basics

1 Consider two coils placed very close to each other, as shown in Figure 10-1. If you apply an AC voltage to the first (or primary) coil, the alternating current flowing through the coil creates a fluctuating magnetic field that surrounds the coil. As the strength and polarity of this magnetic field changes, it induces an alternating current and a corresponding AC voltage in the second (or secondary) coil. The AC signal induced in the secondary coil is at the same frequency as the AC signal applied to the primary coil.

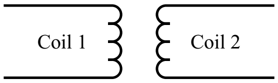

Figure 10-1

Both transformer coils are usually wound around a core made of a magnetic material such as iron or ferrite to increase the strength of the magnetic field.

Questions

A. When the two coils are wound around the same core, are they connected electrically?

____

B. What type of device consists of two wire coils wound around an iron or ferrite core?

____

C. If you apply an AC voltage to the terminals of the primary coil, what occurs in the secondary coil?

____

Answers

A. No.

B. A transformer.

C. An alternating current is induced in the secondary coil, which produces an AC voltage between the terminals of the secondary coil.

2 A transformer is only used with alternating currents. A fluctuating magnetic field (such as that generated by alternating current flowing through a primary coil) is required to induce current in a secondary coil. The stationary magnetic field generated by direct current flowing through a primary coil will not induce any current or voltage in a secondary coil.

When a sine wave signal is applied to a primary coil, you can observe a sine wave of the same frequency across the secondary coil, as shown in Figure 10-2.

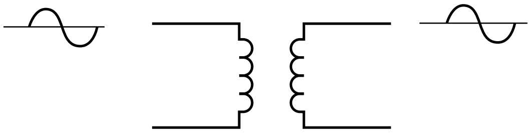

Figure 10-2

Questions

A. What will be the difference in frequency between a signal applied to a primary coil and the signal induced in a secondary coil?

____

B. What will be the voltage difference across a secondary coil if 10 V DC is applied to the primary coil?

____

Answers

A. No difference. The frequencies will be the same.

B. Zero volts. When a DC voltage is applied to the primary coil, there is no voltage or current induced in the secondary coil. You can summarize this by saying that DC does not pass through a transformer.

3 You can compare the output waveform measured between the terminals of the secondary coil to the output waveform measured between the terminals of the primary coil. If the output goes positive when the input goes positive, as shown in Figure 10-3, then they are said to be *in phase*.

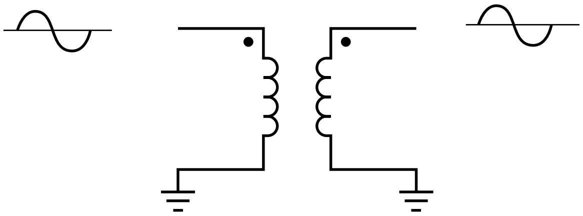

Figure 10-3

The dots on the coils in Figure 10-3 indicate the corresponding end of each coil. If one coil is reversed, then the output will be inverted from the input. The output is said to be *out of phase* with the input, and a dot is placed at the opposite end of the coil.

Question

In Figure 10-4, the output sine wave is out of phase with the input sine wave. Place a dot in the correct location in the secondary coil to show that it is out of phase.

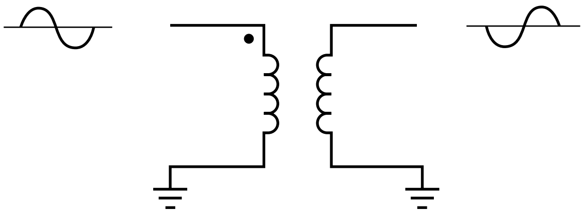

Figure 10-4

Answer

The dot should be at the lower end of the right coil.

4 The transformer shown in the right side of Figure 10-5 has three terminals. The additional terminal, in the middle of the coil, is called a *center tap*.

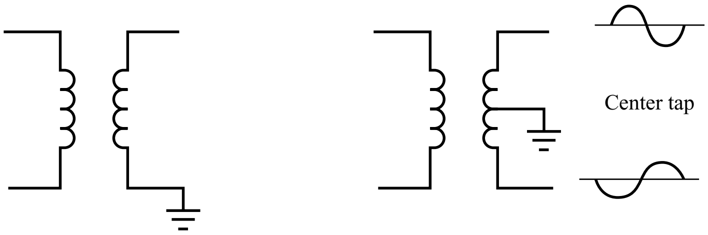

Figure 10-5

Question

What is the difference between the two output waveforms shown for the transformer on the right side of Figure 10-5?

____

Answer

The two waveforms are 180 degrees out of phase. That is, the positive peak of the upper output occurs at the same time as the negative peak of the lower waveform.

5 In a transformer, the output voltage from the secondary coil is directly proportional to the number of turns of wire in the secondary coil. If you increase the number of turns of wire in the secondary coil, a larger output voltage is induced across the secondary coil. If you decrease the number of turns of wire in the secondary coil, a smaller output voltage is induced across the secondary coil.

Question

How does increasing the number of turns of wire in a secondary coil affect the output voltage across the secondary coil?

Answer

It increases the output voltage across the secondary coil.

6 The number of turns in the primary and secondary coils are shown in Figure 10-6 as N_p and N_s.

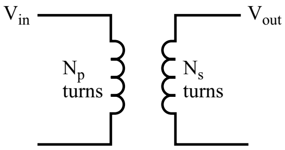

Figure 10-6

Question

The ratio of the input to output voltage is the same as the ratio of the number of turns in the primary coil to the number of turns in the secondary coil. Write a simple formula to express this.

Answer

$$\frac{V_{in}}{V_{out}} = \frac{N_p}{N_s}$$

NOTE **The ratio of primary turns to secondary turns is called the *turns ratio* (TR):**

$$TR = \frac{N_p}{N_s} = \frac{V_{in}}{V_{out}}$$

7 Use the formula from problem 6 to answer the following question.

Question

Calculate the output voltage of a transformer with a 2 to 1 (2:1) turns ratio when you apply a 10 V_{pp} sine wave to the primary coil.

____

Answer

$$\frac{V_{in}}{V_{out}} = \frac{N_p}{N_s} = TR$$

$$V_{out} = V_{in}\frac{N_s}{N_p} = V_{in} \times \frac{1}{TR}$$

$$V_{out} = V_{in} \times \frac{1}{TR} = 10 \times \frac{1}{2} = 5\ V_{pp}$$

8 Use the input voltage and turns ratio for a transformer to answer the following questions.

Questions

Calculate V_{out} in the following:

A. $V_{in} = 20\ V_{pp}$, turns ratio = 5:1.

$V_{out} =$ ____________________________

B. $V_{in} = 1\ V_{pp}$, turns ratio = 1:10.

$V_{out} =$ ____________________________

C. $V_{in} = 100\ V_{rms}$. Find V_{out} when the primary and secondary coil have an equal number of turns.

$V_{out} =$ ____________________________

Answers

A. 4 V_{pp} (This is called a *step down transformer*.)

B. 10 V_{pp} (This is called a *step up transformer*.)

C. 100 V_{rms} (This is called an *isolation transformer*, which is used to separate or isolate the voltage source from the load electrically.)

9 Almost all electronic equipment that is operated from 120 V AC house current requires a transformer to convert the 120 V AC to a more suitable, lower voltage. Figure 10-7 shows a transformer that steps down 120 V AC to 28 V AC.

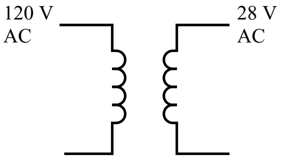

Figure 10-7

Question

Calculate the turns ratio for this transformer.

Answer

$$\text{TR} = \frac{N_p}{N_s} = \frac{120}{28} = 4.3{:}1$$

10 Figure 10-8 shows an oscilloscope trace of the output waveform from the 28 V secondary coil.

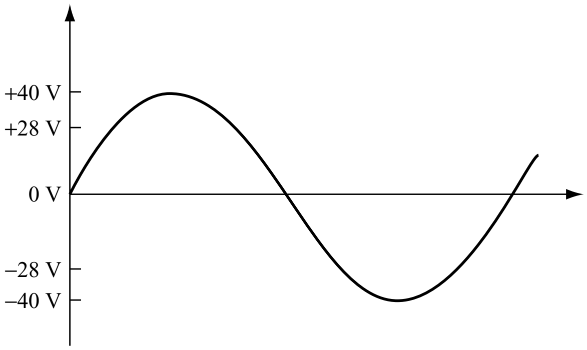

Figure 10-8

Questions

A. Is 28 V a peak-to-peak or an rms value?

B. What is the peak-to-peak value of the 28 V across the secondary coil?

____

Answers

A. rms

B. $2 \times 1.414 \times 28 = 79.184$ V

11 Like the 28 V transformer output value, the 120 V wall plug value is an rms measurement.

Question

What is the peak-to-peak value of the voltage from the wall plug?

____

Answer

Approximately 340 volts

12 The actual voltage measured across the secondary coil of a transformer depends upon where and how you make the measurement. Figure 10-9 illustrates different ways to measure voltage across a 20 V_{pp} secondary coil that has a center tap.

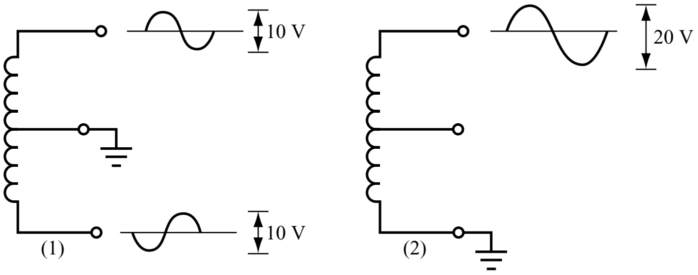

Figure 10-9

If the center tap is grounded as shown in diagram (1) of Figure 10-9, then there is 10 V_{pp} AC between each terminal and ground. You can see that the two output waveforms in diagram (1) are out of phase (180 degrees out of phase, in this case) by comparing the two sine waves shown next to the two terminals. If the bottom terminal is grounded as it is in diagram (2) of Figure 10-9 and the center tap is not used, then there is 20 V_{pp} between the top terminal and ground.

Questions

A. Assume a center-tapped secondary coil is rated at 28 V_{rms} referenced to the center tap. What is the rms voltage output when the center tap is grounded?

____

B. Assume the 28 V_{rms} is the total output voltage across the entire secondary winding. What will be the output voltage between each end of the coil and the center tap?

____

C. Assume the output voltage of a center-tapped secondary coil is 15 V_{rms} between each end of the coil and the center tap. What is the peak-to-peak output voltage when the center tap is not connected?

____

Answers

A. 28 V_{rms} between each end of the coil and the center tap

B. 14 V_{rms} (one half of the total V_{out})

C. When the center tap is not connected, the output is 30 V_{rms}. Therefore, $V_{pp} = 2 \text{ X } 1.414 \text{ X } 30 = 84.84$ volts

13 When the magnetic field induces an AC signal on the secondary coil, there is some loss of power. The percentage of power out of the transformer versus the input power is called the *efficiency* of the transformer. For the sake of this discussion, assume the transformer has an efficiency of 100 percent. Therefore, the output power of the secondary coil equals the power into the primary coil.

Power in = Power out, or $P_{in} = P_{out}$

However, P = VI. Therefore, the following is true:

$$V_{in}I_{in} = V_{out}I_{out}$$

You can rearrange this to come up with the following formula:

$$\frac{I_{out}}{I_{in}} = \frac{V_{in}}{V_{out}} = TR$$

Questions

A. What would be the input current for a transformer if the input power was 12 watts at a voltage of 120 V_{rms}?

____

B. What would be the transformer's output voltage if the turns ratio was 5:1?

____

C. What would be the output current?

____

D. What would be the output power?

____

Answers

NOTE In AC power calculations, you must use the rms values of current and voltage.

A. $I_{in} = \frac{P_{in}}{V_{in}} = \frac{12}{120} = 0.1\,A_{rms}$

B. $V_{out} = \frac{V_{in}}{TR} = \frac{120}{5} = 24\,V_{rms}$

C. $I_{out} = I_{in}\,(TR) = 0.1 \times 5 = 0.5\ A_{rms}$

D. $P_{out} = V_{in}I_{out} = 24 \times 0.5 = 12$ watts (same as the power in)

Transformers in Communications Circuits

14 In communications circuits, an input signal is often received via a very long interconnecting wire, usually called a *line*, which normally has an impedance of 600 ohms. A typical example is a telephone line between two cities.

Question

Communications equipment works best when connected to a load that has the same impedance as the output of the equipment. What output impedance should communications equipment have?

Answer

600 ohms output impedance, to be connected to a 600 ohms line

15 Because most electronic equipment does not have a 600 ohm output impedance, a transformer is often used to connect such equipment to a line. Often, the transformer will be built into the equipment for convenience. The transformer is used to ''match'' the equipment to the line, as shown in Figure 10-10.

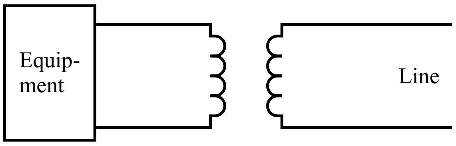

Figure 10-10

To work correctly, the output of the transformer secondary coil should have a 600 ohm impedance to match the line. The output impedance of the transformer (measured at the secondary winding) is governed by two things. One of these is the output impedance of the equipment.

Question

What would you expect the other governing factor to be?

Answer

The turns ratio of the transformer. (The DC resistance of each coil has no effect, and you can ignore it.)

16 Figure 10-11 shows a signal generator with an output impedance of Z_G connected to the primary coil of a transformer. A load impedance of Z_L is connected to the secondary coil.

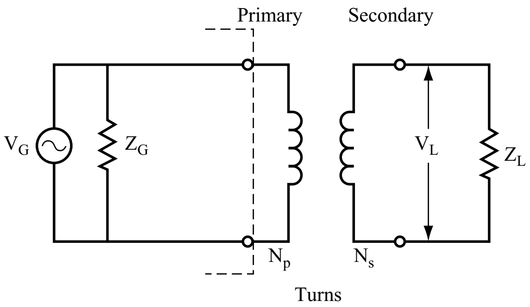

Figure 10-11

You know that $P_{in} = P_{out}$ and that $P = V^2/Z$. Therefore, you can write an equation equating the power of the generator to the power of the load in terms of V and Z, as shown here:

$$\frac{{V_G}^2}{Z_G} = \frac{{V_L}^2}{Z_L}$$

You can rearrange this equation to give the ratio of the voltages, as shown here:

$$\frac{Z_G}{Z_L} = \left(\frac{V_G}{V_L}\right)^2$$

And since $V_G = V_{in}$ and $V_L = V_{out}$ and $V_{in}/V_{out} = N_p/N_s$, the following is true:

$$\frac{Z_G}{Z_L} = \left(\frac{V_{in}}{V_{out}}\right)^2 = \left(\frac{N_p}{N_s}\right)^2 = (TR)^2$$

Therefore, the ratio of the input impedance to the output impedance of a transformer is equal to the square of the turns ratio. As you will see in question A, you can determine the turns ratio for a transformer that will match impedances between a generator and a load. In this way, the generator ‘‘sees’’ an impedance equal to its own impedance, and the load also ‘‘sees’’ an impedance equal to its own impedance.

For the following problem, a generator has an output impedance of 10 kΩ and it produces a 10 V_{pp} (3.53 V_{rms}) signal. It will be connected to a 600 ohm line.

Questions

A. To properly match the generator to the line, what turns ratio is required?

B. Find the output voltage across the load.

C. Find the load current and power.

Answers

A. $\text{TR} = \sqrt{\dfrac{Z_G}{Z_L}} = \sqrt{\dfrac{10{,}000\,\Omega}{600\,\Omega}} = \dfrac{4.08}{1}$ or 4.08:1

B. $V_L = \dfrac{V_G}{\text{TR}} = \dfrac{10}{4.08} = 2.45\,V_{pp}$, which is 0.866 V_{rms}

C. $P_{in} = \dfrac{{V_G}^2}{Z_G} = \dfrac{(3.53)^2}{10{,}000} = 1.25\,\text{mW}$

NOTE **For the power calculation, you must use the RMS value of the voltage.**

$I_{in} = \dfrac{P_{in}}{V_{in}} = \dfrac{1.25\,\text{mW}}{3.53\,V_{rms}} = 0.354\,\text{mA}_{rms}$, which is 1 mA_{pp}

$I_L = I_{in}\,(\text{TR}) = 0.354 \times 4.08 = \mathbf{1.}445\ \text{mA}_{rms}$, which is $\mathbf{4.}08\ \text{mA}_{pp}$

$P_L = \dfrac{{V_L}^2}{Z_L} = \dfrac{(0.866)^2}{600} = 1.25\,\text{mW};$

which is the same as the input power. This circuit is shown in Figure 10-12.

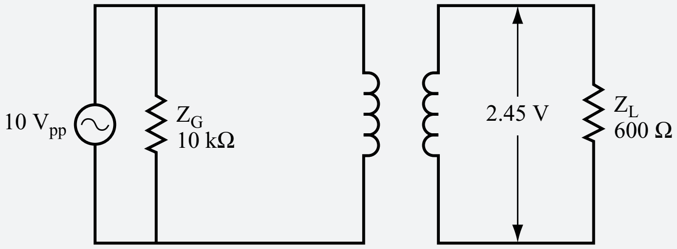

Figure 10-12

NOTE The generator now sees 10 kΩ when it looks toward the load, rather than the actual 600 ohm load. By the same token, the load now sees 600 ohms when it looks toward the source. This condition allows the optimum transfer of power to take place between the source and the load. In practice, however, the optimum condition as calculated here rarely exists. Because it may be impossible to obtain a transformer with a turns ratio of 4.08:1, you would have to select the closest available value, which might be a turns ratio of 4:1. The difference in the turns ratio affects the conditions at the load side, but only slightly.

17 In this problem, you use a transformer to match a generator to a load.

Questions

A. What turns ratio is required to match a generator that has a 2 kΩ output to a 600 ohm line?

____

B. If the generator produces 1 V_{pp}, what is the voltage across the load?

____

Answers

A. TR = 1.83

B. $V_L = 0.55\ V_{pp}$

18 In this problem you use a transformer to match a generator to a 2 kΩ load.

Questions

A. What turns ratio is required to match a 2 kΩ load with a source that has an output impedance of 5 kΩ?

____

B. If the load requires a power of 20 mW, what should the source be? (First, find the voltage across the load.)

____

C. What are the primary and secondary currents and the power supplied by the source to the primary side of the transformer?

____

Answers

A. TR = 1.58

B. $V_L = \sqrt{P_L \times Z_L} = \sqrt{20\ \text{mW} \times 2\ \text{k}\Omega} = 6.32\ V_{rms}$; and
$V_G = V_L \times TR = 6.32\ V_{rms} \times 1.58 = 10\ V_{rms}$

C. $I_L = 3.16\ \text{mA}_{rms}$, $I_p = 2\ \text{mA}_{rms}$, $P_{in} = 20\ \text{mW}$

Summary and Applications

In this chapter, you learned about the following topics related to transformers:

- The principles that allow an AC signal to be induced in a secondary coil
- How the AC voltage across the secondary coil can be stepped up or down depending upon the turns ratio of the transformer
- The use of a center tap to produce various voltages from a transformer
- The use of transformers to match impedances between a generator and a load
- That transformers can cause the output signal to be inverted (out of phase) from the input signal

Self-Test

These questions test your understanding of the material in this chapter. Use a separate sheet of paper for your diagrams or calculations. Compare your answers with the answers provided following the test.

1. How is a transformer constructed?

2. What type of signal is used as an input to a transformer?

3. If a sine wave is fed into a transformer shown in Figure 10-13, what does the output waveform look like?

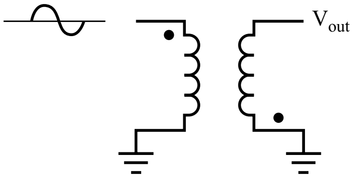

Figure 10-13

4. What is meant by the term *turns ratio*?

5. If $V_{in} = 1\ V_{pp}$ and $TR = 2$, what is the output voltage?

V_{out} __________

6. $V_{in} = 10\ V_{pp}$ and $V_{out} = 7\ V_{pp}$, what is the turns ratio?

TR = __________

7. In the center-tapped secondary winding shown in Figure 10-14, the voltage between points A and B may be expressed as $V_{A\text{-}B} = 28\ V_{pp}$. What is the voltage between C and A?

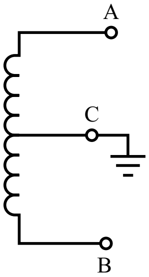

Figure 10-14

8. In the center-tapped secondary winding shown in Figure 10-14, the voltage between points B and C is $V_{B\text{-}C} = 5\ V_{rms}$. What is the peak-to-peak voltage between A and B?

9. If $I_{in} = 0.5\ A_{rms}$ and $I_{out} = 2.0\ A_{rms}$, what is the turns ratio?

10. Is the transformer in problem 9 a step up or a step down transformer?

____

11. If $Z_L = 600$ ohms and $Z_G = 6$ kΩ, find the turns ratio.

TR = ______________________________

12. If $Z_L = 1$ kΩ and the turns ratio is 10:1, what is the generator impedance?

$Z_G =$ ______________________________

Answers to Self-Test

If your answers do not agree with those given here, review the frames indicated in parentheses before you go on to the next chapter.

1.	Two coils of wire wound around a magnetic core (such as iron or ferrite)	(problem 1)
2.	An AC voltage — DC does not work.	(problem 2)
3.	An inverted sine wave	(problem 3)
4.	The ratio of the turns in the primary winding to the number of turns in the secondary coil	(problem 6)
5.	$V_{out} = 0.5$ V	(problem 7)
6.	TR = 1.43:1	(problem 7)
7.	$V_{C\text{-}A} = 14\ V_{pp}$	(problem 12)
8.	$V_{A\text{-}B} = 14.14\ V_{pp}$	(problem 12)
9.	TR = 4:1	(problem 13)
10.	It is a step down transformer. The voltage is lower (stepped down) in the secondary coil than in the primary coil if the current in the secondary coil is higher than the current in the primary coil. This maintains the same power on either side of the transformer.	(problem 13)
11.	TR = 3.2:1	(problem 16)
12.	$Z_G = 100$ kΩ	(problem 16)

CHAPTER 11

Power Supply Circuits

A power supply is incorporated into many electronic devices. Power supplies take the 120 V AC from a wall plug and convert it to a DC voltage, providing power for all types of electronic circuits.

Power supply circuits are very simple in principle, and those shown in this chapter have been around for many years. Because power supplies incorporate many of the features covered in this book, they make an excellent conclusion to your study of basic electronics.

Diodes are a major component in power supplies. Learning how AC signals are affected by diodes is fundamental to your understanding of how power supplies work. Therefore, this chapter begins with a brief discussion of diodes in AC circuits.

Note that throughout this chapter, diagrams show how AC signals are affected by diodes and other components in power supply circuits. If you have an oscilloscope, you can breadboard the circuits and observe these waveforms yourself.

When you complete this chapter, you will be able to do the following:

- Describe the function of diodes in AC circuits.
- Identify at least two ways to rectify an AC signal.
- Draw the output waveforms from rectifier and smoothing circuits.
- Calculate the output voltage from a power supply circuit.
- Determine the appropriate component values for a power supply circuit.

Diodes in AC Circuits Produce Pulsating DC

1 You can use diodes for several purposes in AC circuits, where their characteristic of conducting in only one direction is useful.

Questions

Assume that you apply +20 V DC at point A of the circuit shown in Figure 11-1.

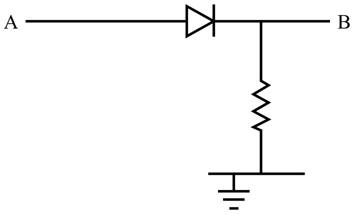

Figure 11-1

A. What is the output voltage at point B?

B. Suppose that you now apply +10 V DC at point B. What is the voltage at point A?

Answers

A. 20 V DC (Ignore, for now, the voltage drop of 0.7 V across the diode.)

B. 0 V (The diode is reverse biased.)

2 Figure 11-2 shows the circuit in Figure 11-1 with a 20 V_{pp} AC input signal centered at +20 V DC.

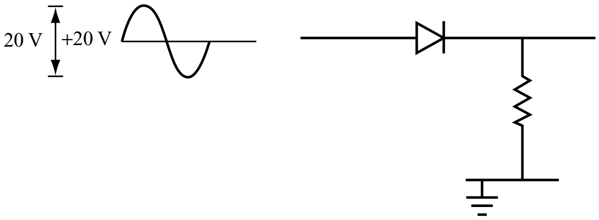

Figure 11-2

Questions

A. What are the positive and negative peak voltages of the input signal?

B. What is the output waveform of this circuit?

Answers

A. Positive peak voltage is 20 V + 10 V = 30 V.

Negative peak voltage is 20 V − 10 V = 10 V.

B. The diode is always forward biased, so it always conducts. Thus, the output waveform is exactly the same as the input waveform.

3 Figure 11-3 shows a circuit with 20 V_{pp} AC input signal centered at 0 V DC.

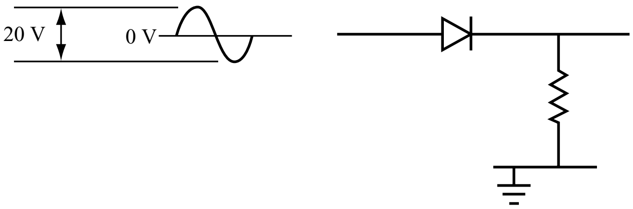

Figure 11-3

Questions

A. What are the positive and negative peak voltages of the input signal?

B. Draw the output waveform on the blank graph provided in Figure 11-4. Remember that only the positive portion of the input waveform passes through the diode.

Figure 11-4

Answers

A. Positive peak voltage is +10 V. Negative peak voltage is −10 V.

B. See Figure 11-5.

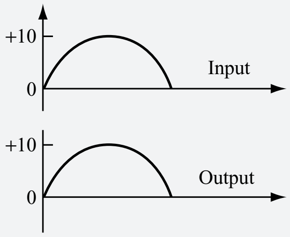

Figure 11-5

4 When the input is negative, the diode in the circuit shown in Figure 11-3 is reverse biased. Therefore, the output voltage remains at 0 V.

Question

Figure 11-6 shows the input waveform for the circuit shown in Figure 11-3. On a separate sheet of paper, draw the output waveform.

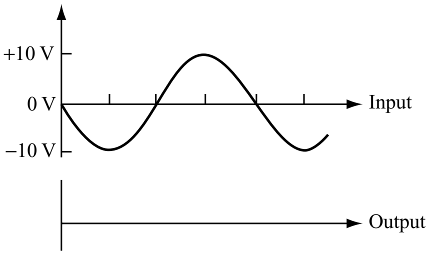

Figure 11-6

Answer

See Figure 11-7.

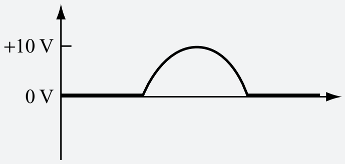

Figure 11-7

5 Figure 11-7 shows the output waveform, of the circuit shown in Figure 11-3, for one complete cycle of the input waveform.

Question

Now, draw the output waveform for three complete cycles of the input waveform shown in Figure 11-6. Use a separate sheet of paper for your drawing.

Answer

See Figure 11-8.

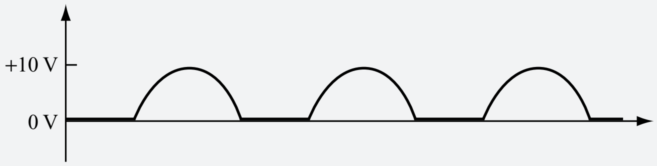

Figure 11-8

6 When the diode is connected in the opposite direction, it is forward biased and, therefore, conducts current when the input signal is negative. In this case, the diode is reverse biased when the input signal is positive. Therefore, the output waveform is inverted from the output waveform shown in Figure 11-8.

Question

On a separate sheet of paper, draw the output waveform for three input cycles, assuming that the diode is connected in the opposite direction from the diode shown in Figure 11-3.

Answer

See Figure 11-9.

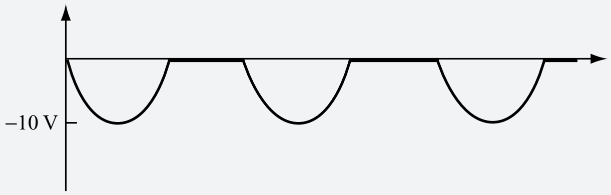

Figure 11-9

7 Figure 11-10 shows a circuit with a 20 V_{pp} AC input signal centered at −20 V DC.

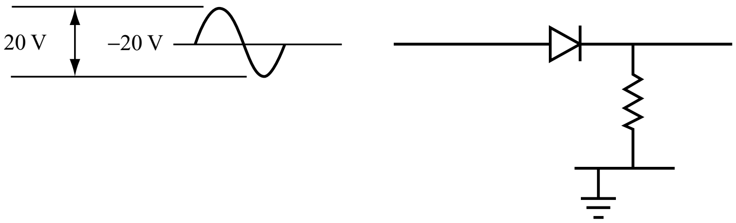

Figure 11-10

Questions

A. When is the diode forward biased?

B. What is the output voltage?

Answers

A. Never, because the voltage that results from adding the AC and DC signals ranges from −10 V to −30 V. Therefore, the diode is always reverse biased.

B. A constant 0 V

8 As you have seen, a diode passes either the positive or negative portion of an AC voltage waveform, depending on how you connect it in a circuit. Therefore, the AC input signal is converted to a pulsed DC output signal, a process called *rectification*. A circuit that converts either the positive or negative portion of an AC voltage waveform to a pulsed DC output signal is called a *half-wave rectifier*.

Question

Refer to the output waveforms shown in Figures 11-8 and 11-9. Do these waveforms represent positive DC voltage pulses or negative DC voltage pulses?

Answer

The waveform In Figure 11-8 represents positive pulses of DC voltage. The waveform in Figure 11-9 represents negative pulses of DC voltage.

9 The circuit shown in Figure 11-11 shows a diode connected to the secondary coil of a transformer.

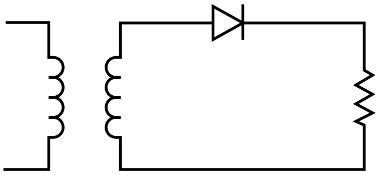

Figure 11-11

Questions

A. How does the diode affect the AC signal?

____

B. Draw the waveform of the voltage across the load for the circuit shown in Figure 11-11 if the secondary coil of the transformer has a 30 V_{pp} AC output signal centered at 0 V DC. Use a separate sheet of paper for your drawing.

Answers

A. The AC signal is rectified.

B. See Figure 11-12. This type of circuit (called a *half-wave rectifier*) produces in an output waveform containing either the positive or negative portion of the input waveform.

Figure 11-12

10 Figure 11-13 shows the waveforms at each end of a center-tap transformer secondary coil. Diode D_1 rectifies the waveform shown at point A and diode D_2 rectifies the waveform shown at point B.

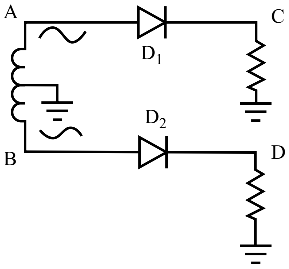

Figure 11-13

Questions

A. Which diode conducts during the first half of the cycle?

B. Which diode conducts during the second half of the cycle?

C. Draw the input waveforms (points A and B), and underneath draw each output waveform (points C and D). Use a separate sheet of paper for your drawing.

Answers

A. During the first half of the cycle, D_1 is forward biased and conducts current. D_2 is reverse biased and does not conduct current.

B. During the second half of the cycle, D_2 is forward biased and conducts current. D_1 is reversed biased and does not conduct current.

C. See Figure 11-14.

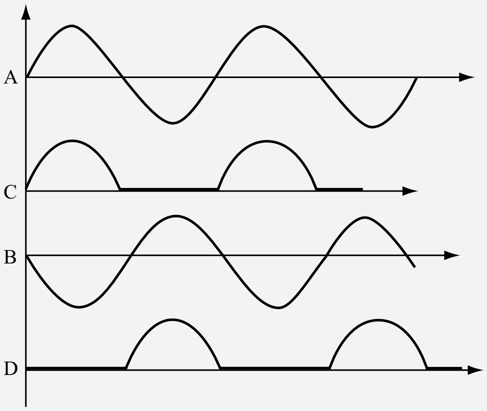

Figure 11-14

11 Figure 11-15 shows a circuit in which diodes connected to the ends of a center-tap transformer are connected to ground through a single resistor. The output voltage waveforms from both diodes are therefore applied across one load resistor. This type of circuit is called a *full-wave rectifier*.

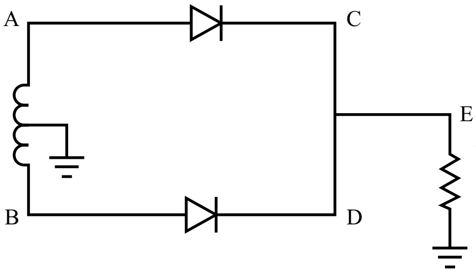

Figure 11-15

Question

On a separate sheet of paper, draw the waveform representing the voltage at point E in the circuit shown in Figure 11-15. (This waveform is a combination of the waveforms at points C and D shown in Figure 11-14.)

Answer

See Figure 11-16.

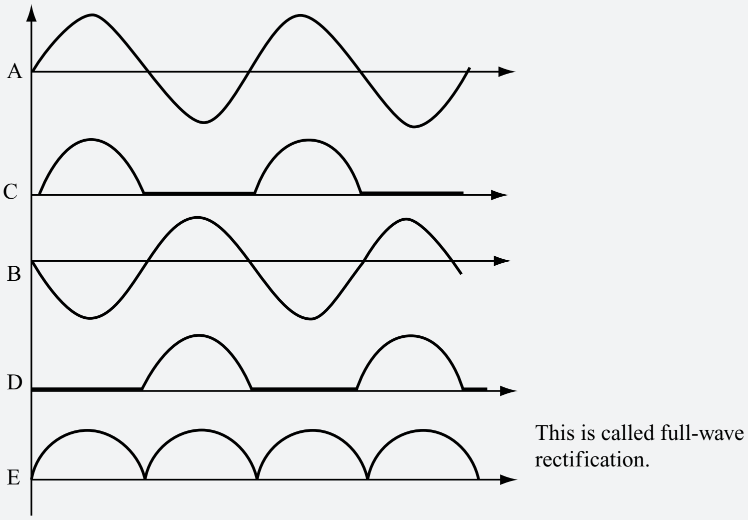

Figure 11-16

12 Full-wave rectification of AC allows a much ''smoother'' conversion of AC to DC than does half-wave rectification.

Figure 11-17 shows a full-wave rectifier circuit that uses a transformer with a two terminal secondary coil, rather than a center-tapped secondary coil.

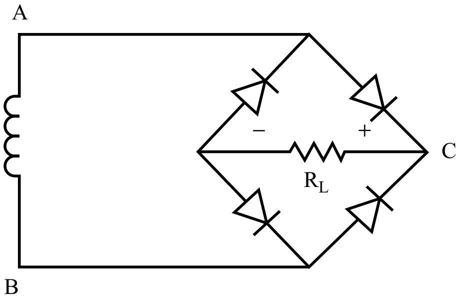

Figure 11-17

Question

How does this circuit differ from the circuit shown in Figure 11-15?

Answer

This circuit has no center tap on the secondary coil, and it uses four diodes.

13 Figure 11-18 shows the direction of current flow when the voltage at point A is positive.

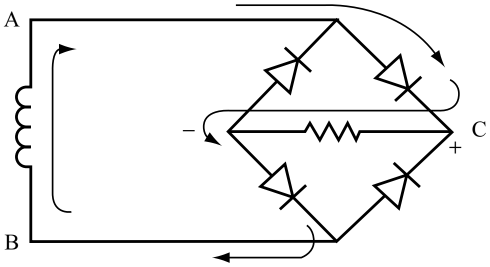

Figure 11-18

Figure 11-19 shows the direction of current flow when the voltage at point B is positive.

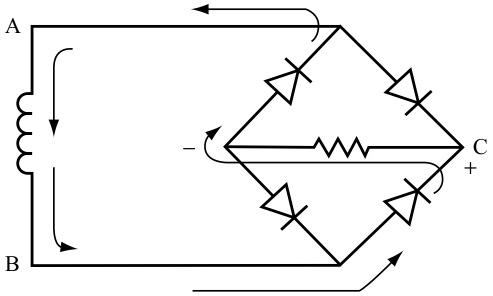

Figure 11-19

Notice that the direction of current through the load resistor is the same in both cases.

Question

A. Through how many diodes does the current travel in each conduction path?

B. Draw the voltage waveform at point C. Use a separate sheet of paper for your drawing.

Answer

A. Two diodes in each case

B. See Figure 11-20.

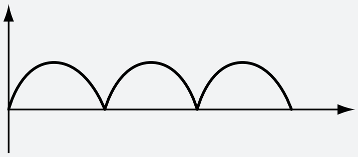

Figure 11-20

What this chapter has explored to this point is how AC is turned into pulsating DC. In fact, rectified AC is often called *pulsating DC*. The next step in your understanding of power supplies is to learn how you turn pulsating DC into level DC.

Level DC (Smoothing Pulsating DC)

14 A basic power supply circuit can be divided into four sections, as shown in Figure 11-21.

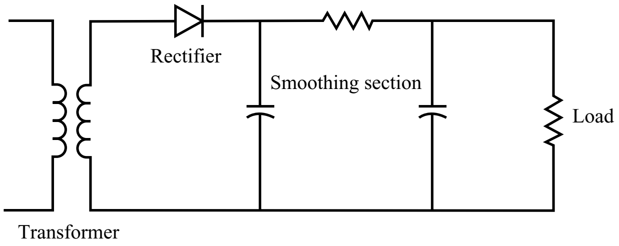

Figure 11-21

Questions

A. If you use a center-tap transformer in a power supply, how many diodes would you need to produce a full-wave rectified output?

____

B. Will the power supply circuit shown in Figure 11-21 result in full- or half-wave rectification?

____

C. What type of output will the rectifier section of the power supply circuit shown in Figure 11-21 produce?

____

Answers

A. Two

B. Half-wave

C. Pulsating DC

15 The function of the smoothing section of a power supply circuit is to take the pulsating DC (PDC) and convert it to a ''pure'' DC with as little AC ''ripple'' as possible. The smoothed DC voltage, shown in the illustration on the right in Figure 11-22, is then applied to the load.

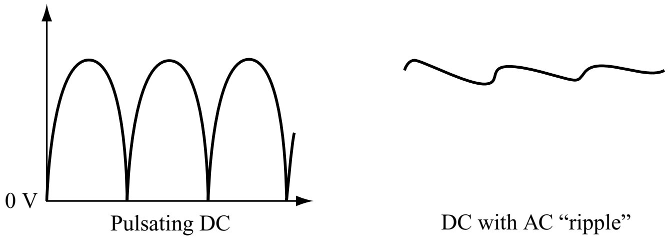

Figure 11-22

The load (which is ''driven'' by the power supply) can be a simple lamp or a complex electronic circuit. Whatever load you use, it will require a certain voltage across its terminals and will draw a current. Therefore the load will have a resistance.

Usually the voltage and current required by the load (and, hence, its resistance) are known, and you must design the power supply to provide that voltage and current.

To simplify the circuit diagrams, you can treat the load as a simple resistor.

Questions

A. What does the smoothing section of a power supply do?

____

B. What is connected to a power supply, and what can you treat it like?

____

Answers

A. The smoothing section converts the pulsating DC to a ''pure'' DC.

B. A load such as a lamp or an electronic circuit is connected to a power supply. In most cases you can treat the load as you do a resistor.

16 Figure 11-23 shows a power supply circuit with a resistor as the load.

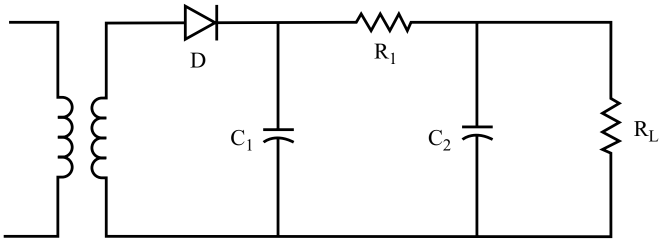

Figure 11-23

Questions

Look at the circuit shown in Figure 11-23 and answer these questions.

A. What type of secondary coil is used?

____

B. What type of rectifier is used?

____

C. What components make up the smoothing section?

____

D. What output would you expect from the rectifier section?

____

Answers

A. A secondary coil with no center tap

B. A single diode half-wave rectifier

C. A resistor and two capacitors (R_1, C_1, and C_2)

D. Half-wave pulsating DC

17 Figure 11-24 shows the output waveform from the rectifier portion of the power supply circuit shown in Figure 11-23.

Figure 11-24

This waveform is the input to the smoothing section of the power supply circuit. Use one of the DC pulses (shown in Figure 11-25) to analyze the effect of the smoothing section on the waveform.

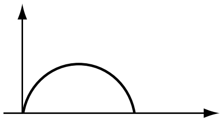

Figure 11-25

As the voltage level of the DC pulse rises to its peak, the capacitor C_1 is charged to the peak voltage of the DC pulse.

When the input DC pulse drops from its peak voltage back to 0 volts, the electrons stored on capacitor C_1 discharge through the circuit. This maintains the voltage across the load resistor at close to its peak value, as shown in Figure 11-26. Note that the DC pulse to the right of the diode stays at the peak voltage, even though V_{in} drops to zero.

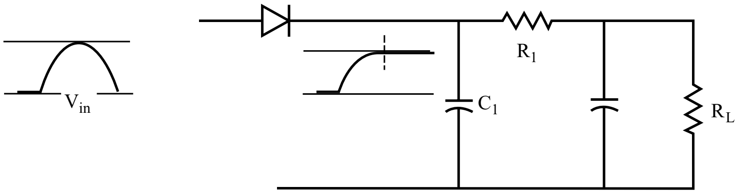

Figure 11-26

Question

What discharge path is available for the capacitor C_1?

Answer

The diode is not conducting, so the capacitor cannot discharge through the diode. The only possible discharge path is through R_1 and the load R_L.

18 If no further pulses pass through the diode, the voltage level drops as the capacitor discharges, resulting in the waveform shown in Figure 11-27.

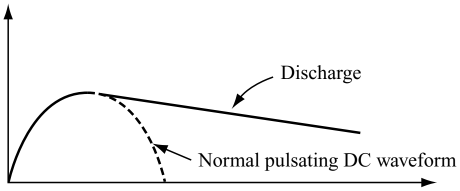

Figure 11-27

However, if another pulse passes through the diode before the capacitor is discharged, the resulting waveform looks like that shown in Figure 11-28.

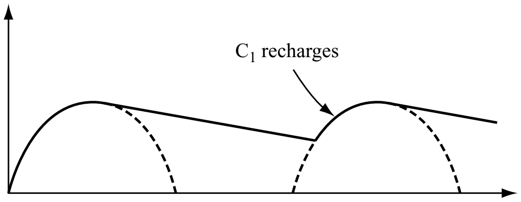

Figure 11-28

The capacitor only discharges briefly before the second pulse recharges it to peak value. Therefore, the voltage applied to the load resistor only drops a small amount.

Applying further pulses can produce this same recharging effect again and again. Figure 11-29 shows the resulting waveform.

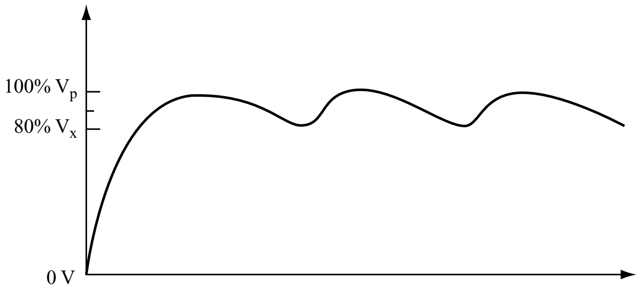

Figure 11-29

The waveform in Figure 11-29 has a DC level with an AC ripple, which varies between V_p and V_x. If you choose values of C_1, R_1, and R_L that produce a discharge time constant for C_1 equal to about 10 times the duration of an input pulse, V_x will be about 80 percent of V_p.

If the discharge time you select is greater than 10 times the duration of an input pulse, the smoothing effect minimizes the AC ripple. A time constant of 10 times the pulse duration results in practical design values that are used throughout this chapter.

NOTE The smoothing section of a power supply circuit is sometimes referred to as a *low pass filter*. Though such a circuit can function as a low pass filter, in the case of a power supply circuit converting AC to DC, it is the release of electrons by the capacitor that is primarily responsible for leveling out the pulsating DC. For that reason, this discussion uses the term *smoothing section*.

Question

Estimate the average DC output level of the waveform shown in Figure 11-29.

Answer

About 90 percent of V_p

19 The output from the secondary coil of the circuit shown in Figure 11-30 is a 28 V_{rms}, 60 Hz sine wave. For this circuit, you need 10 V DC across the 100 ohm load resistor.

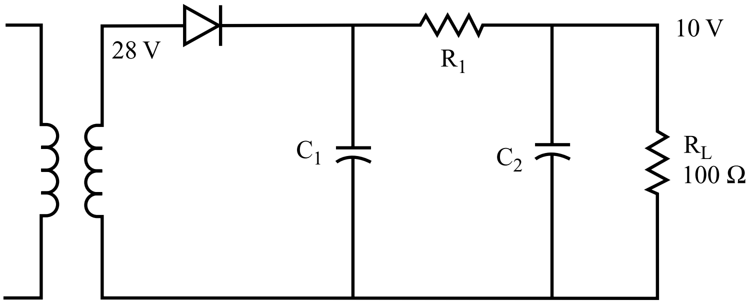

Figure 11-30

Question

What is the peak voltage out of the rectifier?

Answer

The transformer secondary coil delivers 28 V_{rms}, so

$$V_p = \sqrt{2} \times V_{rms} = 1.414 \times 28V_{rms} = 39.59V$$

or about 40 V.

20 Figure 11-31 shows the waveform after the diode has rectified the sine wave for the halfway rectifier circuit shown in Figure 11-30.

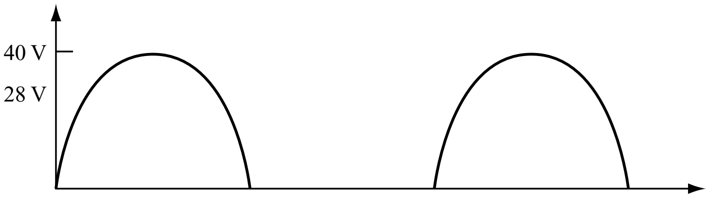

Figure 11-31

Question

Calculate the duration of one pulse.

Answer

60 Hz represents 60 cycles (that is, *wavelengths*) in 1 second. Therefore, one wavelength lasts for 1/60 second.

1/60 second = 1000/60 milliseconds = 16.67 ms

Therefore, the duration of a pulse, which is half a wavelength, is 8.33 ms.

21 The average DC voltage at point B in the circuit shown in Figure 11-30 is about 90 percent of the peak value of the sine wave from the secondary coil, or $V_B = 0.9 \times 40\text{ V} = 36\text{ V}$. R_1 and R_L act as a voltage divider to reduce the 36 V DC level to the required 10 V DC at the output.

Question

Using the voltage divider formula, calculate the value of R_1 that will result in 10 V DC across the 100 ohm load resistor.

Answer

$$V_{out} = \frac{V_{in}R_L}{(R_1 + R_L)}$$

$$10 = \frac{36 \times 100}{(R_1 + 100)}$$

Therefore, $R_1 = 260$ ohms

22 Figure 11-32 shows the half-wave rectifier circuit with the 260 ohm value you calculated for R_1.

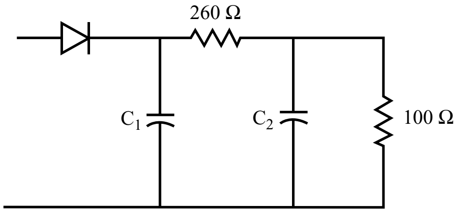

Figure 11-32

Now, choose a value for C_1 that produces a discharge time through the two resistors equal to 10 times the input wave duration.

Questions

A. How long should the discharge time constant be for the circuit in Figure 11-32? Refer to problems 18 and 20.

B. Given the time constant, calculate the value of C_1.

Answers

A. The time constant should be ten times the pulse duration (8.33 ms), so:

$\tau = 10 \times 8.33 \text{ ms} = 83.3 \text{ ms}$ or 0.083 seconds

B. $\tau = R \times C = (R_1 + R_L) \times C_1 = 360 \times C_1$

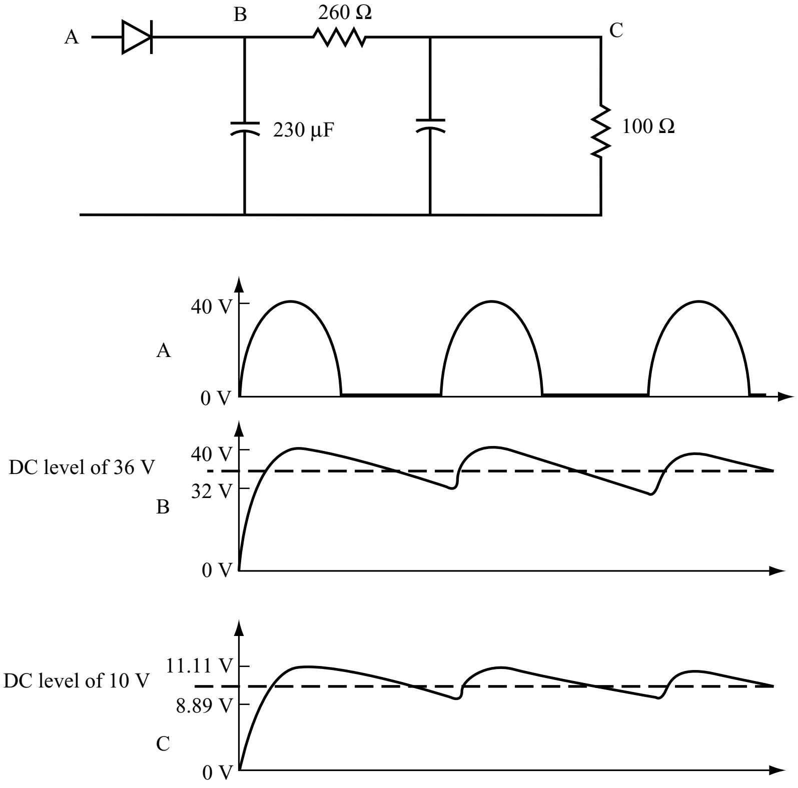
Therefore, $0.0833 = 360 \times C_1$ or $C_1 = 230\ \mu\text{F}$

23 Figure 11-33 shows voltage waveforms at various points in the half-wave rectifier circuit.

Questions

A. What happens to the DC output voltage between points B and C in this circuit?

B. What happens to the waveform between points A and C in the circuit?



A
B
260 Ω
C
230 µF
100 Ω
40 V
A
0 V
DC level of 36 V
40 V
32 V
B
0 V
DC level of 10 V
11.11 V
8.89 V
C
0 V

Figure 11-33

Answers

A. The voltage has been reduced from 36 V to 10 V.

B. The waveform has changed from pulsating DC to a 10 V DC level with an AC ripple.

24 In most cases, the level of the AC ripple is still too high, and further smoothing is required. Figure 11-34 shows the portion of the half-wave rectifier circuit that forms a voltage divider using R_1 and the parallel combination of R_L and C_2. This voltage divider reduces the AC ripple and the DC voltage level.

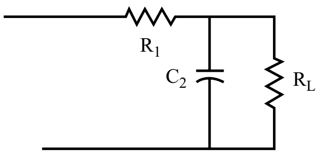


Figure 11-34

Choose a value for C_2 that causes the capacitor's reactance (X_{C2}) to be equal to or less than one tenth of the resistance of the load resistor. C_2, R_1, and R_2 form an AC voltage divider. As discussed in problem 26 of Chapter 6, choosing such a value for C_2 simplifies the calculations for an AC voltage divider circuit containing a parallel resistor and capacitor.

Questions

A. What should the value of X_{C2} be?

B. What is the formula for the reactance of a capacitor?

C. What is the frequency of the AC ripple?

D. Calculate the value of the capacitor C_2.

Answers

A. $X_{C2} = R_L/10 = 100/10 = 10\ \Omega$ or less

B. $X_C = \dfrac{1}{2\pi fC}$

C. 60 Hz. This is identical to the frequency of the sine wave output from the transformer's secondary coil.

D. Solving the reactance formula for C results in the following:

$$C_2 = \frac{1}{2\pi f X_c} = \frac{1}{2 \times \pi \times 60\,\text{Hz} \times 10\,\Omega} = 265\,\mu\text{F}$$

25 Figure 11-35 shows the half-wave rectifier circuit with all capacitor and resistor values.

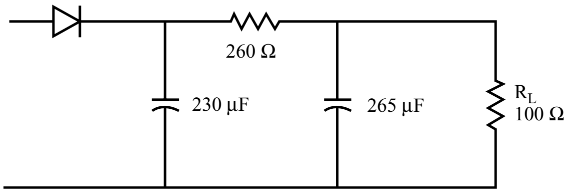

Figure 11-35

Because X_{c2} is one tenth of R_L, you can ignore R_L in AC voltage divider calculations. The resulting AC voltage divider circuit is shown in Figure 11-36.

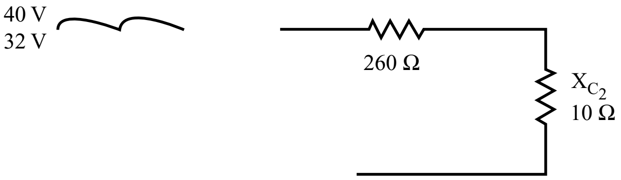

Figure 11-36

Questions

A. What is the peak-to-peak voltage at the input to the AC voltage divider?

B. Find the AC ripple output across R_L using the AC voltage divider formula discussed in problem 26 of Chapter 6.

Answers

A. $V_{pp} = V_p - V_x = 40\text{ V} - 32\text{ V} = 8\text{ V}_{PP}$

B. $$\text{AC V}_{out} = (\text{AC V}_{in}) \times \frac{X_{C2}}{\sqrt{X_{C2}{}^2 + R_1{}^2}}$$

$$\text{AC V}_{out} = 8 \times \frac{10}{\sqrt{(10^2 + 260^2)}} = 0.31\text{ V}_{pp}$$

NOTE **This result means that the addition of C_2 lowers the AC ripple shown by curve C of Figure 11-33, with peak values of 11.11 and 8.89, to values of 10.155 and 9.845 V. This represents a lower ripple at the output. Hence, C_2 aids the smoothing of the 10 V DC at the output.**

26 You can apply the calculations you performed for a half-wave rectifier circuit in the last few problems to a full-wave rectifier circuit. In the next few problems, you calculate the values of R_1, C_1, and C_2 required to provide

10 volts DC across a 100 ohm load for a full-wave rectifier circuit with a 28 V_{rms} sine wave supplied by the secondary coil of a transformer.

Figure 11-37 shows the output waveform from the rectifier section of the circuit.

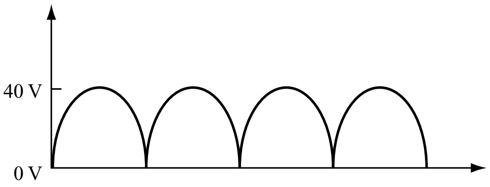

Figure 11-37

Figure 11-38 shows the waveform that results from using a smoothing capacitor

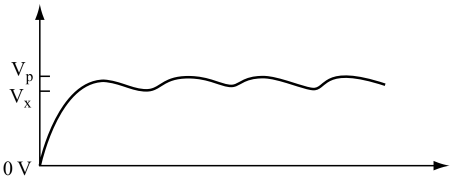

Figure 11-38

If C_1's discharge time constant is ten times the period of the waveform, V_x is about 90 percent of V_p. The average DC level is about 95 percent of V_p.

Questions

A. What is the average DC level for the half-wave rectifier at point B in Figure 11-33?

____

B. What is the average DC level for the waveform in Figure 11-38 given that $V_p = 40$ V?

____

C. Why does a full-wave rectifier have a higher average DC level than a half-wave rectifier?

____

Answers

A. 36 V, which was 90 percent of V_p

B. 38 V, which is 95 percent of V_p

C. The slightly higher values occur because the capacitor does not discharge as far with full-wave rectification, and, as a result, there is slightly less AC ripple. Therefore, V_x is higher and the average DC level is higher.

27 You can use the method for calculating the value of R_1 for a half-wave rectifier (see problem 21) to calculate the value of R_1 for a full-wave rectifier.

Question

Calculate the value of R_1 when $R_L = 100\ \Omega$, $V_{in} = 38$ V, and the required voltage across R_L is 10 V.

Answer

$$V_{out} = 10\text{V} = \frac{V_{in}R_L}{(R_1 + R_L)} = \frac{38 \times 100}{(R_1 + 100)}$$

Therefore, $R_1 = 280$ ohms.

28 You can also use the method for calculating the value of C_1 for a half-wave rectifier (see problem 22) to calculate the value of C_1 for a full-wave rectifier.

Question

Calculate the value of C_1.

Answer

With a time constant of $\tau = 83.3$ ms and a discharge resistance of $R_1 + R_L = 380$ ohms, $C_1 = 220\ \mu\text{F}$.

29 You can use the voltage divider equation to find the amount of AC ripple across the load resistor for a full-wave rectifier with $R_1 = 280\ \Omega$ and $R_L = 100\ \Omega$. For $V_p = 40$ V, the calculation results in 10.52 V. For $V_x = 36$ V, the calculation results in 9.47 V. Therefore, the voltage levels at the load resistor vary between 10.52 V and 9.47 V, with an average DC level of 10 V. You can reduce the AC ripple by adding a second capacitor in parallel with the load resistor.

Questions

Use the method for calculating the value of C_2 for the half-wave rectifier in problem 24.

A. Calculate the reactance of the second capacitor (C_2).

____

B. Calculate the value of C_2. (Note that the frequency of the AC ripple for the full-wave rectifier is 120 Hz.)

____

Answers

A. The reactance should be one tenth (or less) of the load resistance. Therefore, it should be 10 ohms or less.

B. $$C_2 = \frac{1}{2\pi f X_C} = \frac{1}{2 \times \pi \times 120\,\text{Hz} \times 10\,\Omega} = 135\,\mu\text{F}$$

30 The AC ripple at the first smoothing capacitor ranges from 36 V to 40 V. The AC ripple at the load ranges from 9.47 V to 10.52 V when there is only one capacitor in the circuit.

Question

Calculate the upper and lower values of the AC ripple at the output if you use a second capacitor with a value of 135 μF in parallel with the load resistor. You can use the same formulas as those for the half-wave rectifier in problem 25. Note that X_{C2} is 10 Ω from problem 29; $R_1 = 280$ from problem 27; and AC $V_{in} = V_p - V_x = (40\text{ V} - 36\text{ V}) = 4\ V_{pp}$.

____

Answer

$$\text{AC V}_{\text{out}} = (\text{AC V}_{\text{in}}) \times \frac{X_{C2}}{\sqrt{(R_1{}^2 + X_{C2}{}^2)}} = 0.143\,\text{V}_{\text{pp}}$$

The result of approximately 0.14 V_{pp} means that the output will now vary from 10.07 to 9.93 V. This shows that the second capacitor lowers the ripple significantly. The AC ripple is less than half of the ripple shown for the half-wave rectifier in problem 25. In other words, a full-wave rectifier produces a smoother DC output than a half-wave rectifier.

31 Figure 11-39 shows a full-wave rectifier circuit with an output voltage of 5 V across a 50 Ω load resistor. Use the following steps to calculate the values of the other components.

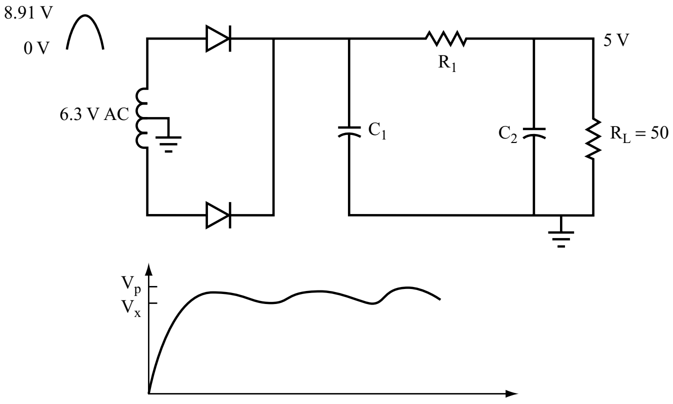

Figure 11-39

Questions

A. What are V_p, V_x, and the DC level at the first capacitor?

B. Calculate the value of R_1 required to make the DC level at the output 5 V.

C. Calculate the value of C_1.

D. Calculate the value of C_2.

E. What is the amount AC ripple at the output?

F. Draw the final circuit showing the calculated values. Use a separate sheet of paper for your drawing.

Answers

A. $V_p = 6.3 \times \sqrt{2} = 8.91\,V$, $V_x = 90$ percent of $V_p = 8.02\,V$

The DC level is 95 percent of V_p, which is 8.46 V.

B. About 35 ohms.

C. 980 μF.

D. Using $X_{c2} = 5$ ohms and 120 Hz, $C_2 = 265\,\mu F$.

E. At the input to the smoothing section, the AC variation is 8.91 to 8.02, or 0.89 V_{pp}. Using the AC voltage divider equation with $R_1 = 35$ ohms and $X_{c2} = 5$ ohms, AC V_{out} equals about 0.13 V_{pp}. Therefore, the AC variation at the output is 5.065 to 4.935 V, a very small AC ripple.

F. See Figure 11-40.

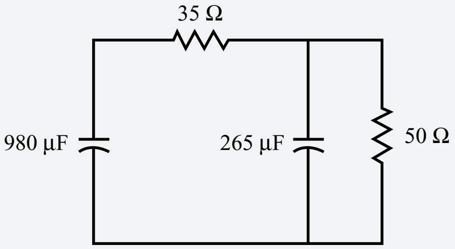

Figure 11-40

Using the simple procedure shown here always produces a working power supply circuit. This is not the only design procedure you can use for power supplies, but it is one of the simplest and most effective.

Summary

This chapter introduced the following concepts and calculations related to power supplies:

THE EFFECTS OF DIODES ON AC SIGNALS

- Methods of rectifying an AC signal
- Half-wave and full-wave rectifier circuit designs
- The calculations you can use to determine component values for half-wave and full-wave rectifier power supply circuits

Self-Test

These questions test your understanding of the information presented in this chapter. Use a separate sheet of paper for your diagrams or calculations. Compare your answers with the answers provided following the test.

In questions 1 through 5, draw the output waveform of each circuit. The input is given in each case.

1. See Figure 11-41.

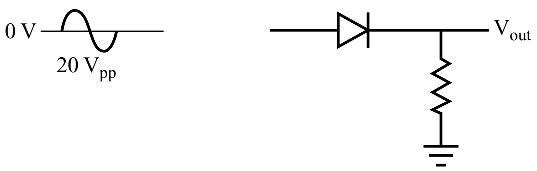

Figure 11-41

2. See Figure 11-42.

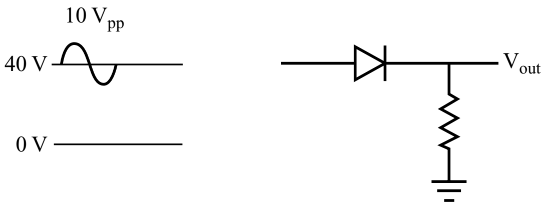

Figure 11-42

3. See Figure 11-43.

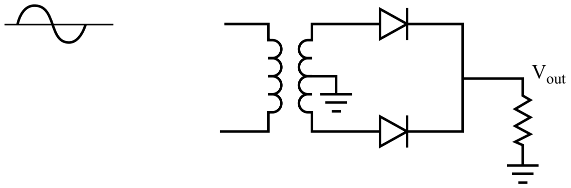

Figure 11-43

4. See Figure 11-44.

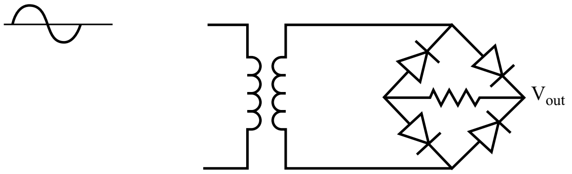

Figure 11-44

5. See Figure 11-45.

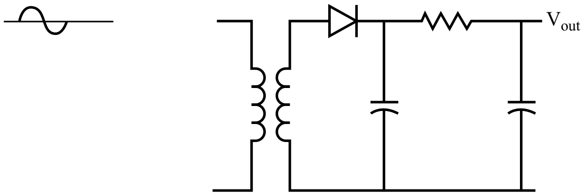

Figure 11-45

6. In the circuit shown in Figure 11-46, 100 V_{rms} at 60 Hz appears at the secondary coil of the transformer; 28 V DC with as little AC ripple as possible is required across the 220 ohm load. Find R_1, C_1, and C_2. Find the approximate AC ripple.

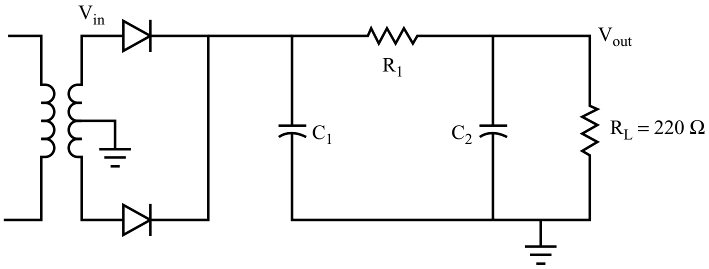

Figure 11-46

Answers to Self-Test

If your answers do not agree with those given here, review the problems indicated in parentheses.

1. See Figure 11-47. (problems 1–5)

Figure 11-47

2. See Figure 11-48. (problem 2)

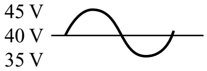

Figure 11-48

3. See Figure 11-49. (problem 11)

Figure 11-49

4. See Figure 11-50. (problem 13)

Figure 11-50

5. See Figure 11-51. (problems 15–18)

Figure 11-51

6. $R_1 = 833$ ohms, $C_1 = 79\ \mu F$, let $X_{c2} = 22$ ohms and then $C_2 = 60\ \mu F$ (problems 26–30)

$$\text{AC}\,V_{out} = 14 \times \frac{22}{\sqrt{(22^2 \times 833^2)}} = 0.37\,V_{pp}$$

CHAPTER 12

Conclusion and Final Self-Test

In this book, you have discovered basic concepts and formulas that will provide a foundation for your studies in modern electronics, whether you become a dedicated hobbyist, or go on to study electrical or electronics engineering.

Conclusion

Having read this book, you should now know enough to read intermediate-level electronics books and articles intelligently, to build electronics circuits and projects, and to pursue electronics to whatever depth and for whatever reason you wish. Specifically, you should now be able to do the following:

- Recognize all the important, discrete electronics components in a schematic diagram.
- Understand how circuits that use discrete components work.
- Calculate the component values needed for circuits to function efficiently.
- Design simple circuits.
- Build simple circuits and electronics projects.

To see how much you have learned, you may want to take the final self-test at the end of this chapter. It tests your comprehension of the concepts and formulas presented throughout this book.

Once you complete the following self-test and feel confident that you have mastered the information in this book, refer to Appendix E for additional resources for further learning, including the following:

- Books such as *The Art of Electronics* by Paul Horowitz and Winfield Hill (New York: Cambridge University Press, 1989) provide a great next step in further electronics study.
- You can buy books that step you through electronics projects, such as *Electronics Projects For Dummies* by Earl Boysen and Nancy Muir (Indianapolis: Wiley, 2006), to help you get set up and get hands-on practice.
- You can browse Web sites for electronic project ideas.
- Earl Boysen's Web site, `www.buildinggadgets.com`, provides tips, ideas, and links to a variety of great online resources.

NOTE **For those interested in more serious study, you should be aware that there is a difference between the path you take to become an electrician (or technician) and an electrical (or electronics) engineer. Training for electronics technicians is available in military trade schools, public and private vocational schools, and in many high schools. Engineers are required to understand the mathematical details in more depth, and must take at least a four-year curriculum at an accredited college or university.**

Whatever your goal, you can feel confident that this book has given you a solid grounding for your future studies. Wherever you go in electronics, good luck!

Final Self-Test

This final test allows you to assess your overall knowledge of electronics. Answers and review references follow the test. Use a separate sheet of paper for your calculations and drawings.

1. If R = 1 MΩ and I = 2 μA, find the voltage.

2. If V = 5 V and R = 10 kΩ, find the current.

3. If V = 28 V and I = 4 A, find the resistance.

4. If 330 ohms and 220 ohms are connected in parallel, find the equivalent resistance.

5. If V = 28 V and I = 5 mA, find the power.

6. If the current through a 220 ohm resistor is 30.2 mA, what is the power dissipated by the resistor?

7. If the power rating of a 1000 ohm resistor is 0.5 watts, what will be the maximum current that should safely flow through the resistor?

8. If a 10 ohm resistor is in series with a 32 ohm resistor and the combination is across a 12 volt supply, what is the voltage drop across each resistor, and what will the two voltage drops add up to?

9. A current of 1 ampere splits between 6 ohm and 12 ohm resistors in parallel. Find the current through each.

10. A current of 273 mA splits between 330 ohm and 660 ohm resistors in parallel. Find the current through each resistor.

11. If $R = 10\ k\Omega$ and $C = 1\ \mu F$, find the time constant.

12. If $R = 1\ M\Omega$ and $C = 250\ \mu F$, find the time constant.

13. Three capacitors of 1 μF, 2 μF, and 3 μF are connected in parallel. Find the total capacitance.

14. Three capacitors of 100 μF, 220 μF, and 220 μF are connected in series. Find the total capacitance.

15. Three capacitors of 22 pF, 22 pF, and 33 pF are connected in series. Find the total capacitance.

16. What is the knee voltage for a germanium diode?

17. What is the knee voltage for a silicon diode?

18. In the circuit shown in Figure 12-1, $V_S = 5$ V, R = 1 kΩ, find the current through the diode, I_D.

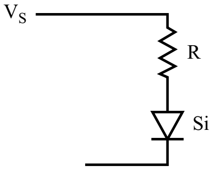

Figure 12-1

19. For the circuit in question 15, V = 12 V and R = 100 ohms. Find I_D.

20. For the circuit shown in Figure 12-2, $V_S = 100$ V, $R_1 = 7.2$ kΩ, $R_2 = 4$ kΩ, and $V_Z = 28$ V. Find the current through the zener diode, I_Z.

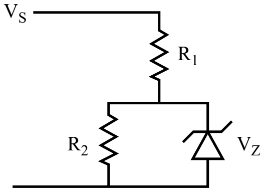

Figure 12-2

21. For the circuit in Figure 12-2, $V_S = 10$ V, $R_1 = 1$ kΩ, $R_2 = 10$ kΩ, and $V_Z = 6.3$ V. Find I_Z.

22. Use the circuit shown in Figure 12-3 to answer this question.

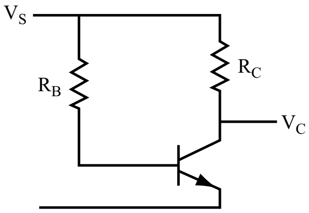

Figure 12-3

Find the DC collector voltage, V_C, if $V_S = 28$ V, $\beta = 10$, $R_B = 200$ kΩ, $R_C = 10$ kΩ.

23. Again using the circuit shown in Figure 12-3, find R_B if $V_S = 12$ V, $\beta = 250$, $R_C = 2.2$ kΩ, $V_C = 6$ V.

24. Using the circuit shown in Figure 12-3, find β if $V_S = 10$ V, $R_B = 100$ kΩ, $R_C = 1$ kΩ, $V_C = 5$ V.

25. What are the three terminals for a JFET called, and which one controls the operation of the JFET?

When is the drain current of a JFET at its maximum value?

26. Use the circuit shown in Figure 12-4 to answer this question.

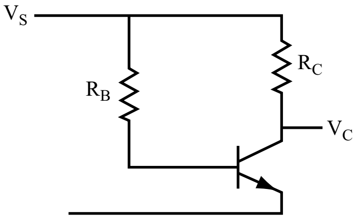

Figure 12-4

Find the value of R_B required to turn the transistor ON if $V_S = 14$ V, $R_C = 10$ kΩ, $\beta = 50$.

27. Again, using the circuit shown in Figure 12-4, find the value of R_B required to turn the transistor ON if $V_S = 5$ V, $R_C = 4.7$ kΩ, $\beta = 100$.

28. Use the circuit shown in Figure 12-5 to answer this question.

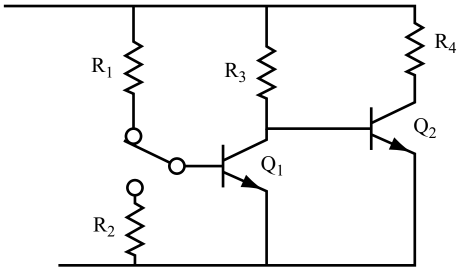

Figure 12-5

Find the values of R_1, R_2, and R_3 that will enable the switch to turn Q_2 ON and OFF, if $V_S = 10$ V, $\beta_1 = 50$, $\beta_2 = 20$, $R_4 = 2.2$ kΩ.

---

29. Again, using the circuit shown in Figure 12-5, find the values of R_1, R_2, and R_3 that will enable the switch to turn Q_2 ON and OFF if $V_S = 28$ V, $\beta_1 = 30$, $\beta_2 = 10$, $R_4 = 220$ Ω.

---

30. An N-channel JFET has a drain saturation current of $I_{DSS} = 14$ mA. If a 28 V drain supply is used, calculate the drain resistance, R_D.

---

31. Draw one cycle of a sine wave.

---

32. Mark in V_{pp}, V_{rms}, and the period of the waveform on your drawing for question 31.

---

33. If $V_{pp} = 10$ V, find V_{rms}.

---

34. If $V_{rms} = 120$ V, find V_{pp}.

---

35. If the frequency of a sine wave is 14.5 kHz, what is the period of the waveform?

---

36. Find the reactance X_C for a 200 μF capacitor when the frequency is 60 Hz.

---

37. Find the value of the capacitance that gives a 50 ohm reactance at a frequency of 10 kHz

---

38. Find the inductive reactance X_L for a 10 mH inductor when the frequency is 440 Hz.

---

39. Find the value of the inductance that has 100 ohms reactance when the frequency is 1 kHz.

40. Find the series and parallel resonant frequency of a 0.1 μF capacitor and a 4 mH inductor that has negligible internal resistance.

41. For this question refer to the circuit shown in Figure 12-6.

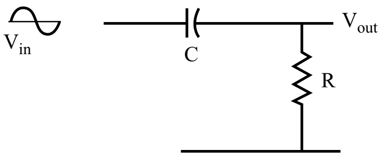

Figure 12-6

Find X_C, Z, V_{out}, I, tan θ, and θ if $V_{in} = 10\ V_{pp}$, f = 1 kHz, C = 0.1 μF, R = 1600 ohms.

42. Again, using the circuit shown in Figure 12-6, find X_C, Z, V_{out}, I, tan θ, and θ if $V_{in} = 120\ V_{rms}$, f = 60 Hz, C = 0.33 μF, R = 6 kΩ.

43. For this question, refer to the circuit shown in Figure 12-7.

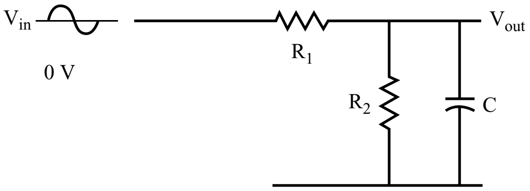

Figure 12-7

Find X_C, AC V_{out}, and DC V_{out} if $V_{in} = 1\ V_{pp}$ AC, riding on a 5 V DC level; f = 10 kHz; R_1 = 10 kΩ; R_2 = 10 kΩ; C = 0.2 μF.

44. Again, using the circuit shown in Figure 12-7, find X_C, AC V_{out}, and DC V_{out} if $V_{in} = 0.5\ V_{pp}$ AC, riding on a 10 V DC level; f = 120 Hz; R_1 = 80 ohms; R_2 = 20 ohms; C = 1000 μF.

45. For this question, refer to the circuit shown in Figure 12-8.

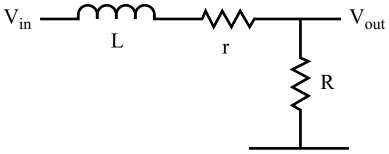

Figure 12-8

In this circuit, $V_{in} = 10\ V_{pp}$ AC, riding on a 5 V DC level; f = 1 kHz; L = 10 mH; r = 9 ohms; R = 54 ohms. Find AC V_{out}, DC V_{out}, X_L, Z, tan θ, and θ.

---

46. In the circuit shown in Figure 12-9, L = 1 mH, C = 0.1 μF, and R = 10 ohms.

Figure 12-9

Find f_r, X_L, X_C, Z, Q, and the bandwidth.

---

47. In the circuit shown in Figure 12-10, L = 10 mH, C = 0.02 μF, and r = 7 ohms.

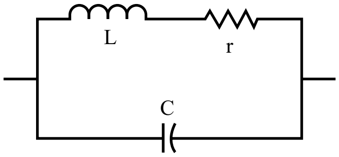

Figure 12-10

Find f_r, X_L, X_C, Z, Q, and the bandwidth.

---

48. If the voltage across the resonant circuit of question 47 is at a peak value of 8 V at the resonant frequency, what is the voltage at the half power points?

What are the half power frequencies?

---

49. Use the amplifier circuit shown in Figure 12-11 to answer this question.

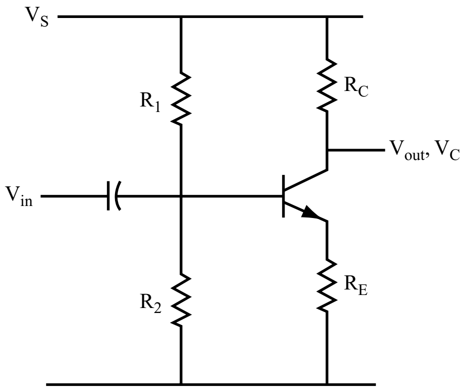

Figure 12-11

Find the values of R_1, R_2, and R_E that will provide the amplifier with a voltage gain of 10. Use $V_S = 28$ V, $R_C = 1$ kΩ, $\beta = 100$.

---

50. Again, using the circuit shown in Figure 12-11, find the values of R_1, R_2, and R_E that will provide the amplifier a voltage gain of 20. Use $V_S =$ 10 V, $R_C = 2.2$ kΩ, $\beta = 50$.

---

51. Using the circuit shown in Figure 12-11, how would you modify the amplifier in question 50 to obtain a maximum gain? Assume that the lowest frequency it has to pass is 50 Hz.

---

52. Using the JFET amplifier circuit shown in problem 42 of Chapter 1, with a bias point of $V_{GS} = -2.8$ V, a drain current of $I_D = 2.7$ mA, and $V_{DS} =$ 12 V, find the values of R_S and R_D.

---

53. If the transconductance of the JFET used in question 52 is 4000 μmhos, what will the AC voltage gain be?

---

54. A certain op-amp circuit uses an input resistance of 8 kΩ to an inverting input. In order for the op-amp circuit to have a gain of 85, what should the value of the feedback resistance be?

---

55. If the input to the op-amp circuit of question 54 is 2 mV, what is the output?

56. What is an oscillator?

57. Why is positive feedback rather than negative feedback necessary in an oscillator?

58. What feedback method is used in a Colpitts oscillator?

59. What feedback method is used in a Hartley oscillator?

60. Draw the circuit of a Colpitts oscillator.

61. Draw the circuit of a Hartley oscillator.

62. What is the formula used to calculate the output frequency of an oscillator?

63. Draw the circuit symbol for a transformer with a center tap.

64. Name the two main coils used on a transformer.

65. What is the equation that shows the relationship between the input voltage, the output voltage, and the number of turns in each coil of a transformer?

66. What is the equation that shows the relationship between the turns ratio and the currents in the primary and secondary coils of the transformer?

____

67. What is the equation that shows the relationship between the impedance of the primary coil, the impedance of the secondary coil, and the number of turns in each coil of a transformer?

____

68. What are the two main uses for transformers?

____

69. Draw a simple half-wave rectifier circuit with a smoothing filter at the output.

____

70. Draw a simple full-wave rectifier circuit using a center tap transformer and a smoothing filter at the output.

____

71. Given a 10 V_{rms} input to a full-wave rectified power supply, calculate the values of R_1, C_1 and C_2 (see Figure 12-12) that results in a 5 V DC output across a 50 ohm load.

____

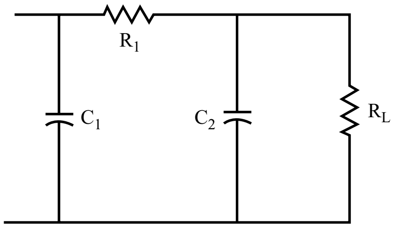

Figure 12-12

Answers to Final Self-Test

The references in parentheses to the right of the answers give you the chapter and problem number where the material is introduced so that you can easily review any concepts covered in the test.

1.	V = 2 V	(Chapter 1, problem 5)
2.	I = 0.5 mA	(Chapter 1, problem 6)
3.	R = 7 ohms	(Chapter 1, problem 7)
4.	132 ohms	(Chapter 1, problem 10)
5.	P = 140 milliwatts or 0.14 watts	(Chapter 1, problems 13 and 14)
6.	0.2 W	(Chapter 1, problems 13 and 15)
7.	22.36 mA	(Chapter 1, problems 13 and 16)
8.	2.86 V, 9.14 V, 12 V	(Chapter 1, problems 23 and 26)
9.	2/3 A through the 6 ohm resistor; 1/3 A through the 12 ohm resistor	(Chapter 1, problem 28 or 29)
10.	91 mA through the 660 ohm resistor; 182 mA through the 330 ohm resistor	(Chapter 1, problem 28 or 29)
11.	$\tau = 0.01$ seconds	(Chapter 1, problem 34)
12.	$\tau = 250$ seconds	(Chapter 1, problem 34)
13.	6 μF	(Chapter 1, problem 40)
14.	52.4 μF	(Chapter 1, problem 41)
15.	8.25 μF	(Chapter 1, problem 41)
16.	Approximately 0.3 V	(Chapter 2, problem 10)
17.	Approximately 0.7 V	(Chapter 2, problem 10)
18.	$I_D = 4.3$ mA	(Chapter 2, problem 14)
19.	$I_D = 120$ mA	(Chapter 2, problem 14)
20.	$I_Z = 3$ mA	(Chapter 2, problem 31)
21.	$I_Z = 3.07$ mA	(Chapter 2, problem 31)
22.	$V_C = 14$ V	(Chapter 3, problems 21–24)
23.	$R_B = 1.1$ MΩ	(Chapter 3, problems 21–24)
24.	$\beta = 50$	(Chapter 3, problems 21–24)
25.	Drain, source, and gate, with the gate acting to control the JFET	(Chapter 3, problem 29)
26.	$R_B = 500$ kΩ	(Chapter 4, problems 8)
27.	$R_B = 470$ kΩ	(Chapter 4, problems 4–8)

28. $R_3 = 44\ \text{k}\Omega$, $R_1 = 2.2\ \text{k}\Omega$, $R_2 = 2.2\ \text{k}\Omega$	(Chapter 4, problems 19–23)
29. $R_3 = 2.2\ \text{k}\Omega$, $R_1 = 66\ \text{k}\Omega$, $R_2 = 66\ \text{k}\Omega$	(Chapter 4, problems 19–23)
30. $R_D = 2\ \text{k}\Omega$	(Chapter 4, problem 39)
31. See Figure 12-13.	(Chapter 5, problem 7)

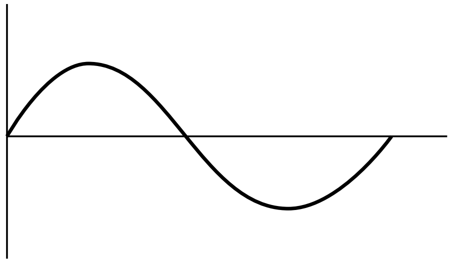

Figure 12-13

32. See Figure 12-14.	(Chapter 5, problems 3 and 7)

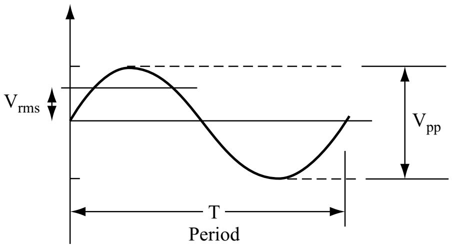

Figure 12-14

33. 3.535 V	(Chapter 5, problem 4)
34. 340 V	(Chapter 5, problem 5)
35. 69 μsec	(Chapter 5, problem 7)
36. 13.3 ohms	(Chapter 5, problem 14)
37. 0.32 μF	(Chapter 5, problem 14)
38. 27.6 ohms	(Chapter 5, problem 17)
39. 16 mH	(Chapter 5, problem 17)
40. 8 kHz	(Chapter 5, problems 19 and 21)
41. $X_C = 1.6\ \text{k}\Omega$, $Z = 2263$ ohms, $V_{out} = 7.07$ V, $I = 4.4$ mA, $\tan\theta = 1$, $\theta = 45$ degrees	(Chapter 6, problems 10 and 23)

42. $X_C = 8\ \text{k}\Omega$, $Z = 10\ \text{k}\Omega$, $V_{out} = 72$ V, I = 12 mA, $\tan\theta = 1.33$, $\theta = 53.13$ degrees	(Chapter 6, problems 10 and 23)
43. $X_C = 80$ ohms, AC $V_{out} = 8$ mV, DC $V_{out} = 2.5$ V	(Chapter 6, problem 26)
44. $X_C = 1.33$ ohms, AC $V_{out} = 8.3$ mV, DC $V_{out} = 2$ V	(Chapter 6, problem 26)
45. $X_L = 62.8$ ohms, Z = 89 ohms, AC $V_{out} = 6.07$ V, DC $V_{out} = 4.3$ V, $\tan\theta = 1$, $\theta = 45$ degrees	(Chapter 6, problems 31 and 35)
46. $f_r = 16$ kHz, $X_L = 100$ ohms, $X_C = 100$ ohms, Z = 10 ohms, Q = 10, BW = 1.6 kΩ	(Chapter 7, problems 2, 6, and 20)
47. $f_r = 11{,}254$ Hz, $X_L = X_C = 707$ ohms, $Z = 71.4\ \text{k}\Omega$, Q = 101, BW = 111 Hz	(Chapter 7, problems 10, 11, and 20)
48. $V_{hp} = 5.656$ V, $f_{1hp} = 11{,}198$ Hz, $f_{2hp} = 11{,}310$ V	(Chapter 7, problem 27)
49. Your values should be close to the following: $R_E = 100$ ohms, $V_C = 14$ V, $V_E = 1.4$ V, $V_B = 2.1$ V, $R_2 = 1.5\ \text{k}\Omega$, $R_1 = 16.8\ \text{k}\Omega$	(Chapter 8, problem 17)
50. $R_E = 110$ ohms, $V_C = 5$ V, $V_E = 0.25$ V, $V_B = 0.95$ V, $R_2 = 2.2\ \text{k}\Omega$, $R_1 = 18.1\ \text{k}\Omega$	(Chapter 8, problem 17)
51. The gain can be increased by using a capacitor to bypass the emitter resistor R_E; $C_E = 300\ \mu\text{F}$ (approximately).	(Chapter 8, problem 20)
52. $R_S = 1.04\ \text{k}\Omega$, $R_D = 3.41\ \text{k}\Omega$	(Chapter 8, problem 42)
53. $A_v = -13.6$	(Chapter 8, problem 39)
54. $R_F = 680\ \text{k}\Omega$	(Chapter 8, problem 45)
55. $V_{out} = 170$ mV and is inverted	(Chapter 8, problem 45)
56. An *oscillator* is a circuit that emits a continuous sine wave output, without requiring an input signal. Other types of oscillators exist that do not have sine wave outputs, but they are not discussed in this book.	(Chapter 9, introduction)
57. Positive feedback causes the amplifier to sustain an oscillation or sine wave at the output. Negative feedback causes the amplifier to stabilize, which reduces oscillations at the output.	(Chapter 9, problems 2 and 3)
58. A capacitive voltage divider	(Chapter 9, problem 14)

59. An inductive voltage divider (Chapter 9, problem 14)

60. See Figure 12-15. (Chapter 9, problem 24)

62. $f_r = \dfrac{1}{2\pi\sqrt{LC}}$ (Chapter 9, problem 11)

63. See Figure 12-17. (Chapter 10, problem 4)

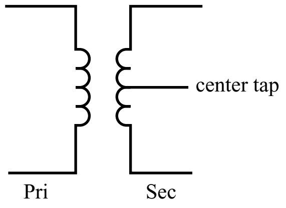

Figure 12-17

64. Primary and secondary (Chapter 10, problem 2)

65. $V_{in}/V_{out} = V_P/V_S = N_P/N_S = TR$ (Chapter 10, problem 6)

66. $I_{out}/I_{in} = I_S/I_P = N_P/N_S = TR$ (Chapter 10, problem 13)

67. $Z_{in}/Z_{out} = (N_P/N_S)^2$, or impedance ratio, is the square of the turns ratio (Chapter 10, problem 16)

68. They are used for stepping up or stepping down an AC voltage, and to match impedances between a generator and a load (Chapter 10, introduction)

69. See Figure 12-18. (Chapter 11, problem 14)

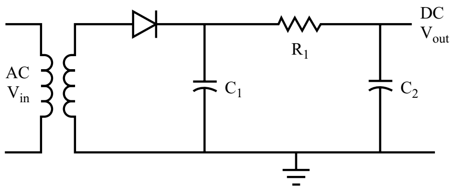

Figure 12-18

70. See Figure 12-19. (Chapter 11, problem 31)

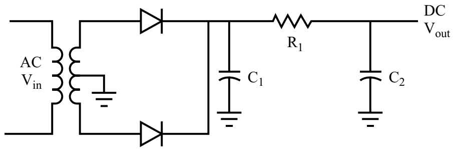

Figure 12-19

71. $R_1 = 84$ ohms, $C_1 = 622\ \mu F$, $C_2 = 265\ \mu F$ (Chapter 11, problems 26–29)

APPENDIX A

Glossary

Ampere (A) The unit of measurement of electric current.

Amplifier Electronic device or circuit that produces an output signal with greater power, voltage, or current than that provided by the input signal.

Capacitance (C) The capability of a component to store an electric charge when voltage is applied across the component, measured in farads.

Capacitor A component that stores electric charge when voltage is applied to it, that can return the charge to a circuit in the form of electric current when the voltage is removed.

Discrete components Individual electronic parts such as resistors, diodes, capacitors, and transistors.

Diode A component that conducts current in one direction only.

Farad (F) The unit of measurement of capacitance.

Feedback A connection from the output of an amplifier back to the input, where a portion of the output voltage is used to control, stabilize, or modify the operation of the amplifier.

Frequency (f) Number of cycles of a waveform that occur in a given time period, measured in hertz (cycles per second).

Ground Zero volts. This is the arbitrary reference point in a circuit from which all voltage measurements are made.

Henry (H) The unit of measurement of inductance.

Impedance (Z) Total opposition (resistance and reactance) of a circuit to AC current flow, measured in ohms.

Inductance (L) The property of a component that opposes any change in an existing current, measured in henrys.

Inductor A coil of wire whose magnetic field opposes changes in current flow when the voltage across the coil is changed.

Integrated circuit (IC) Electronic component in the form of a very small silicon chip in which numerous transistors and other components have been built to form a circuit.

Kirchhoff's laws A set of formulas that form the basis for DC and AC circuit analysis, including: *current law (KCL):* The sum of all currents at a junction equals zero; and *voltage law (KVL):* The sum of all voltages in a loop equals zero.

Ohm (Ω) The unit of measurement of resistance.

Ohm's law A formula used to calculate the relationship between voltage, current, and resistance, expressed as $V = IR$. Also expressed as $E = IR$.

Operational amplifier (op-amp) An integrated circuit, multi-stage amplifier. An op-amp is much smaller and, therefore, more practical than an equivalent amplifier made with discrete components.

Oscillator An electronic circuit that produces a continuous output signal such as a sine wave or square wave.

Phase angle For a signal, the angle of lead or lag between the current waveform and the voltage waveform.

Phase shift The change in phase of a signal as it passes through a circuit, such as in an amplifier.

Power The expenditure of energy over time. Power is measured in watts.

Reactance (X) The degree of opposition of a component to the flow of alternating current (AC), measured in ohms. There are two types of reactance: capacitive reactance (X_C) exhibited by capacitors and inductive reactance (X_L) exhibited by inductors.

Rectification The process of changing alternating current (AC) to direct current (DC).

Resistance (R) The degree of opposition of a component to the flow of electric current, measured in ohms.

Resistor A component whose value is determined by the amount of opposition it has to the flow of electric current.

Semiconductor A material that has electrical characteristics of a conductor or an insulator, depending on how it is treated. Silicon is the semiconductor material most commonly used in electronic components.

Transformer A component that transforms an input AC voltage to either a higher level (step up transformer) or a lower level (step down transformer) AC voltage.

Transistor, BJT A bipolar junction transistor (BJT) is a semiconductor component that can either be used as a switch or an amplifier. In either case, a small input signal controls the transistor, producing a much larger output signal.

Transistor, JFET A junction field effect transistor (JFET), like the bipolar junction transistor, can be used either as a switch or an amplifier.

Transistor, MOSFET Metal oxide silicon field effect transistor (MOSFET); like the BJT and JFET, a MOSFET can be used either as a switch or an amplifier. The MOSFET is the most commonly used transistor in integrated circuits.

Turns ratio (TR) The ratio of the number of turns in the primary or input winding of a transformer to the number of turns in the secondary or output winding.

Volt (V) The unit of measurement for the potential difference that causes a current to flow through a conductor.

Watt (W) Unit of electric power dissipated as heat when 1 amp of current flows through a component that has 1 volt applied across it.

Zener A particular type of diode that will flow current at a definite reverse-bias voltage level.

APPENDIX B

List of Symbols and Abbreviations

The following table lists common symbols and abbreviations.

SYMBOL/ABBREVIATION	MEANING
A	Ampere
AC	Alternating current
A_V	AC voltage gain
β (beta)	Current gain
BW	Bandwidth
C	Capacitor
DC	Direct current
F	Farad
g_m	Transconductance
f	Frequency
f_r	Resonant frequency
H	Henry

SYMBOL/ABBREVIATION	MEANING
Hz	Hertz
I	Electric current
I_B	Base current
I_C	Collector current
I_D	Drain current of a FET; also current through a diode
I_{DSS}	Saturation current
L	Inductor
LC	Inductor-capacitor circuit
N_P	Number of turns in a primary coil
N_S	Number of turns in a secondary coil
Ω	Ohms
P	Power
Q	Transistor, also the Q value of a resonant circuit
R	Resistor
R_{in}	Input resistance of a transistor
r	DC resistance of an inductor
T	Period of a waveform
τ	Time constant
TR	Turns ratio
θ	Phase angle
V	Voltage
V_C	Voltage at the collector of a transistor
V_{DD}	Drain supply voltage
V_E	Voltage at the emitter of a transistor
V_{GG}	Gate supply voltage
V_{GS}	Gate to source voltage
$V_{GS(off)}$	Gate to source cutoff voltage
V_{in}	AC voltage of an input signal
V_{out}	AC output voltage

SYMBOL/ABBREVIATION	MEANING
V_P	Peak voltage
V_{PP}	Peak-to-peak voltage
V_{rms}	Root mean square voltage
V_S	Supply voltage
W	Watts
X_C	Reactance of a capacitor
X_L	Reactance of an inductor
Z	Impedance

APPENDIX C

Powers of Ten and Engineering Prefixes

The following table shows powers of the number 10, decimal equivalents, prefixes used to denote the value, symbols used, and an example.

POWER	DECIMAL	PREFIX	SYMBOL	EXAMPLE
10^9	1,000,000,000	Giga-	G	Gohms
10^6	1,000,000	Mega-	M	Mohms
10^3	1,000	Kilo-	k	kohms
10^{-3}	0.001	Milli-	m	mA
10^{-6}	0.000,001	Micro-	μ	μA
10^{-9}	0.000,000,001	Nano-	n	nsec
10^{-12}	0.000,000,000,001	Pico-	p	pF

APPENDIX

D

Standard Composition Resistor Values

The most commonly-used type of resistor is the carbon composition resistor with a ± 5 percent tolerance and either a 1/4 or 1/2 watt power rating, The standard resistance values for this type of resistor are listed here (in ohms). You should be able to purchase resistors at any of these values through the online distributors listed in Appendix E. Power resistors are available with fewer resistance values, which you can find in various suppliers' catalogs.

NOTE In the following, "k" represents kilo-ohms, so 7.5 k translates into 7,500 ohms. Similarly, "M" stands for megohms, so a value of 3.6 M represents 3,600,000 ohms.

2.2	24	270	3.0 k	33 k	360 k
2.4	27	300	3.3 k	36 k	390 k
2.7	30	330	3.6 k	39 k	430 k
3	33	360	3.9 k	43 k	470 k
3.3	36	390	4.3 k	47 k	510 k
3.6	39	430	4.7 k	51 k	560 k
3.9	43	470	5.1 k	56 k	620 k

4.3	47	510	5.6 k	62 k	680 k
4.7	51	560	6.2 k	68 k	750 k
5.1	56	620	6.8 k	75 k	820 k
5.6	62	680	7.5 k	82 k	910 k
6.2	68	750	8.2 k	91 k	1.0 M
6.8	75	820	9.1 k	100 k	1.2 M
7.5	82	910	10 k	110 k	1.5 M
8.2	91	1.0 k	11 k	120 k	1.8 M
9.1	100	1.1 k	12 k	130 k	2.2 M
10	110	1.2 k	13 k	150 k	2.4 M
11	120	1.3 k	15 k	160 k	2.7 M
12	130	1.5 k	16 k	180 k	3.3 M
13	150	1.6 k	18 k	200 k	3.6 M
15	160	1.8 k	20 k	220 k	3.9 M
16	180	2.0 k	22 k	240 k	4.7 M
18	200	2.2 k	24 k	270 k	5.6 M
20	220	2.4 k	27 k	300 k	6.8 M
22	240	2.7 k	30 k	330 k	8.2 M

APPENDIX E

Supplemental Resources

The following list of books, magazines, tutorials, and electronics suppliers may be of interest to the reader who is seeking more knowledge regarding either basic electronics concepts, reference material for circuit design, or the supplies needed to build circuits.

Web Sites

- *Building Gadgets* (`www.buildinggadgets.com/`) — An electronics reference site maintained by Earl Boysen (one of the authors of this book). There are lots of handy links to electronics tutorials, discussion forums, suppliers, and interesting electronics projects here.
- *All About Circuits* (`www.allaboutcircuits.com/`) — Includes an online book on electronics theory and circuits, as well as discussion forums on electronics projects, microcontrollers, and general electronics issues.
- *Electronics Tutorials* (`www.electronics-tutorials.com/`) — Tutorials on a wide range of electronics topics.
- *Williamson Labs* (`www.williamson-labs.com/`) — Tutorials on electronics components and circuits. Many of these tutorials include

animated illustrations that may help you understand how each circuit functions.

- *Electro Tech online* (`www.electro-tech-online.com/`) — Discussion forum on electronics projects and general electronics issues.
- *Electronics Lab* (`www.electronics-lab.com/forum/`) — Discussion forum on project design, electronics theory, and microcontrollers along with a collection of a few hundred interesting projects.
- *Discover Circuits* (`www.discovercircuits.com/`) — A collection of thousands of electronics circuits.

Books

- *Electronics For Dummies, First Edition, by Gordon McComb and Earl Boysen (Indianapolis: Wiley, 2005)* — A good book to start with; provides an introduction to electronics concepts, components, circuits, and methods.
- *The Art of Electronics, Second Edition, by Paul Horowitz and Winfield Hill. (New York: Cambridge University Press, 1989)* — Useful reference book for designing circuits as well as understanding the functionality of existing circuits.
- *2008 ARRL Handbook for Radio Communications (Newington, Connecticut: American Radio Relay League, 2008)* — While this is intended for ham radio enthusiasts, it is also a useful reference book for understanding circuit design.
- *Electronics Projects For Dummies, First Edition, by Earl Boysen and Nancy C. Muir (Indianapolis: Wiley, 2006)* — Provides an introduction and hands-on practice in building electronic circuits and projects.

Magazines

- *Everyday Practical Electronics Magazine* (`www.epemag.wimborne.co.uk/`) — Information on new components for hobbyists and projects with focus on circuits using discrete components.

- *Nuts and Volts Magazine* (`nutsvolts.com/`) — Information on new components for hobbyists and projects with focus on circuits using microcontrollers.
- *EDN Magazine* (`www.edn.com/`) — Articles on new components/ designs for the engineering community.

Suppliers

This section shows retail stores and online distributors.

Retail Stores

- *Radio Shack* (`www.radioshack.com/`) — Has stores in most U.S. cities that carry electronic components.
- *Fry's Electronics* (`www.frys.com/`) — Has stores in nine states that carry electronics components.

Online Distributors

- *Jameco Electronics* (`www.jameco.com/`) — A medium-sized distributor that carries most of the components you'll need with a reasonably sized catalog that it's easy to find components in.
- *Mouser Electronics* (`www.mouser.com/`) — A large distributor that carries a wide range of components with a nice ordering system on their Web site that lets you put together separate orders for different projects, very handy if you're planning multiple projects. They also do a very good job of packaging, clearly labeling components for shipment.
- *Digi-key* (`www.digikey.com/`) — Another large distributor with a very broad selection of components. Digi-key may carry components that are hard to find at smaller suppliers.

APPENDIX F

Equation Reference

The following table provides a quick reference to common equations.

PARAMETER		EQUATION	CHAPTER REFERENCE
Bandwidth		$BW = \frac{f_r}{Q}$	Chapter 7, problem 20
Capacitance			
	Parallel Capacitance	$C_T = C_1 + C_2 + \cdots + C_N$	Chapter 1, Summary
	Series Capacitance	$\frac{1}{C_T} = \frac{1}{C_1} + \frac{1}{C_2} + \cdots + \frac{1}{C_N}$, or $C_T = \frac{1}{\frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3} + \cdots + \frac{1}{C_N}}$, or $C_T = \frac{C_1 C_2}{C_1 + C_2}$ for two capacitors	Chapter 1, Summary

PARAMETER		EQUATION	CHAPTER REFERENCE
Frequency		$f = \frac{1}{T}$	Chapter 5, problem 7
	Resonance Frequency (series LC circuit)	$f_r = \frac{1}{2\pi\sqrt{LC}}$	Chapter 7, problem 6
	Resonance Frequency (parallel LC circuit)	$f_r = \frac{1}{2\pi\sqrt{LC}}\sqrt{1 - \frac{r^2C}{L}}$ if Q is less than10 $f_r = \frac{1}{2\pi\sqrt{LC}}$, if $Q \geqslant 10$	Chapter 7, problem 10
Gain			
	Voltage Gain	$A_V = \frac{V_{out}}{V_{in}}$	Chapter 8, problem 9
	Current Gain	$\beta = \frac{I_C}{I_B}$	Chapter 3, problem 17
Impedance		$Z = \sqrt{X_C{}^2 + R^2}$	Chapter 6, problem 8
Phase Shift			
	Phase Angle (RC circuit)	$\tan\theta = \frac{X_C}{R} = \frac{1}{2\pi fRC}$	Chapter 6, problem 23
	Phase Angle (LC circuit)	$\tan\theta = \frac{X_L}{R} = \frac{2\pi fL}{R}$	Chapter 6, problem 35
Q Value		$Q = \frac{X_L}{R}$	Chapter 7, problem 20
Resistance			
	Parallel Resistance	$\frac{1}{R_T} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3} + \cdots + \frac{1}{R_N}$, or $R_T = \frac{1}{\frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3} + \cdots + \frac{1}{R_N}}$, or $R_T = \frac{R_1R_2}{R_1 + R_2}$ for two resistors	Chapter 1, Summary

PARAMETER		EQUATION	CHAPTER REFERENCE
	Series Resistance	$R_T = R_1 + R_2 + \cdots + R_N$	Chapter 1, Summary
Power		$P = VI$, or $P = I^2R$, or $P = \frac{V^2}{R}$	Chapter 1, Summary
Reactance			
	Capacitive Reactance	$X_C = \frac{1}{2\pi fC}$	Chapter 5, problem 13
	Inductive Reactance	$X_L = 2\pi fL$	Chapter 5, problem 16
Time Constant		$\tau = RC$	Chapter 1, Summary
Turns Ratio		$TR = \frac{N_p}{N_s}$	Chapter 11, problem 7
Voltage			
	Ohm's Law (DC)	$V = IR$	Chapter 1, Summary
	Ohm's Law (AC)	$V = IZ$	Chapter 6, problem 8
	Voltage divider	$V_1 = \frac{V_S R_1}{R_T}$	Chapter 1, Summary
	Peak-to-Peak Voltage (sine wave)	$V_{pp} = 2V_p = 2 \times \sqrt{2} \times V_{rms}$ $= 2.828 \times V_{rms}$	Chapter 5, problem 4
	RMS Voltage (sine wave)	$V_{rms} = \frac{1}{\sqrt{2}} \times V_p = \frac{1}{\sqrt{2}} \times \frac{V_{pp}}{2}$ $= 0.707 \times \frac{V_{pp}}{2}$	Chapter 5, problem 4
	Transformer output voltage	$V_{out} = \frac{V_{in} N_s}{N_p}$	Chapter 11, problem 7

APPENDIX

G

Schematic Symbols Used in This Book

The following table shows schematic symbols used in this book.

COMPONENT		SYMBOL
Battery		Capacitor		
Diodes		
	Diode		Zener Diode	Generator (DC)		
COMPONENT		SYMBOL
Ground		
Inductor		Lamp		Meters		
	Meter		Ammeter		Voltmeter	Motor		Operational Amplifier		Resistors		
	Resistor		Variable Resistor (Potentiometer)	Signal Generator (Sine Wave)		
COMPONENT		SYMBOL
Switches		
	Single-pole, Single-throw (SPST) Switch		Single-pole, Double-throw (SPDT) Switch	Transformers		
	Transformer		Center Tap Transformer	Transistor		
	NPN BJT		PNP BJT		N-channel JFET		P-channel JFET	
Index

Index

A

AC (alternating current), 22
  circuits
    capacitors, 154–156, 165–167
    inductor, 156–158
    inductors, 190–197
    resistors, 152–154
  diodes in AC circuits, 347–358
  ripple, 359
  signal, capacitor, 187
  signals, 152
    capacitors passing, 166
  sine waves and, 147
AC reactance of an inductor, 156
algebraic formula for Ohm's law, 3
alternative base switching, 131–137
ammeter, 41
amperes
  microampere, 11
  milliampere, 11
amplifiers
  analyzing, 271–275
  common base amplifier, 298
  common collector amplifier, 265
  common emitter amplifier, 296–297
  feedback, 294
  input resistance, 265
  JFET as, 275–284
  lowest frequency passed, 273
  operational amplifier, 284–288
  output resistance, 265
  parallel inductor and capacitor, 299
  resonant load, 299
  stability, 252–256
  tuned load, 299
  two-stage, 264
  voltage gain, 249
anode, 36
  forward biased diode, 38
  voltage, 38
Armstrong method, 304
Armstrong oscillator, 316
attenuation, 181
  f_r, 218

B

ß (beta), 84–85
  finding of transistor, 87–97
band of frequencies, 221
band-reject filter, 222
bandpass filter, 221
bandwidth of circuits, 221
  calculating, 223
base-collector diode, 75
  current flow, 79

base current
  collector current, 84
  flow, 110
  need for, 110
base-emitter diode, 75
  current flow, 80
  voltage drop, 111
base-emitter junction, current flow from supply voltage to, 115
batteries, 2, 3
  voltage, 13
biasing, 243, 256–265
bipolar junction transistors. *See* BJT (bipolar junction transistors)
bipolar transistors, 71
BJT (bipolar junction transistors), 71
  terminals, 97
Boysen, Earl, 378
break down of diode, 57
BW, 221

C

capacitors
  AC, 22
  AC circuits, 154–156
  capacitor charging graph, 24
  DC circuit, 22–28
  DC signal, 187
  emitter bypass capacitor, 261
  and inductor in series, 208–218
  level of opposition, 168
  passing AC signals, 166
  reactance, 155, 166
  resistors and, 186–190
  in series, 167–174
  voltage, 24, 181
cascading transistor amplifiers, 264
cathode, 36
  voltage, 38
center tap, 332
characteristic curve of a diode, 41
chemically generating electric current, 2
circuits
  bandwidth, 221
    calculating, 223
  breaking, 20
  completing, 20
  RLC, 208
  time constant, 23
  transistors, soldering, 72
coils, 236
  number of turns, 333
  oscillators, 317
  reversed, 331
  transformers, 329–330
collector, current flow to base, 116
collector current
  base current and, 84
  calculating, 110
collector-emitter voltage, 89
collector voltage, ON transistor, 109
Colpitts method, 304
Colpitts oscillator circuit, 308–313
  feedback connections, 310
common base amplifier, 298
  oscillators and, 301
common collector amplifier, 265
common emitter amplifier, 296–297
  oscillators and, 301
communications circuits, transformers in, 338–343
conventional current flow, 3
current
  closed switches, 20
  definition, 2
  KCL (Kirchhoff's current law), 19
  open switches, 20
current divider, 17–20
current flow, 1–4, 3
  direction, 81
  magnetic field and, 234
current gain, 84
  formula, 85
currents, small currents, 11–12
cutoff point, 246
cutoff voltage, 140

D
DC circuit, capacitors in, 22–28
DC (direct current), 1
  level, 358–373
  pre-test, 30–33
  pulsating, diodes in AC circuits, 347–358
  pure, 359
  resistance, 156
  signal, capacitor, 187
  smoothing pulsating, 358–373
diode
  in AC circuits, 347–358
  forward biased, 38
  perfect diode, 39
  reverse biased, 39
diode junction, 36
diodes, 35
  backward in circuit, 55
  base-collector diode, 75
  base-emitter diode, 75
  break down, 57
  experiment, 40–45
  germanium, 36
  power dissipated, 51
  silicon, 36
  V-I curve, 41
    perfect diode, 56
  zener diode, 58–65
direction of current flow, 81
doping, 36
dry-labbing, 40

E
efficiency of transformer, 337
electric current
  definition, 2
  generating, 2
    chemically, 2
    electrochemical reaction, 2
    magnetically, 2
    photovoltaic generation of electrons, 2
    piezoelectrical, 3
    thermal generation, 2
electrochemical reaction, 2
electron flow, 3
Electronics Projects For Dummies, 378
emitter bypass capacitor, 261
emitter follower, 265–271
  output impedance, 265
emitter voltage, ON transistor, 109
exponential curve, 25

F
f_3, signal output voltage, 218
f_4, signal output voltage, 218
feedback, 304–308
  Armstrong method, 304
  Colpitts method, 304
  feedback resistor, 287
  Hartley method, 304
  negative, 294–295
  positive, 295–296
  voltage, calculating, 307
formulas, for power, 8–9
forward biased diode, 38
  closed switches and, 40
forward transfer admittance, 280
f_r, attenuation, 218
frequencies
  band of, 221
  blocked by circuit, 219
  range of, 221
frequency response graphs, half power frequencies, 219
fuel cells, 2
full-wave rectifier, 355
function generator, 148

G
gain
  accurate amounts, 262
  op-amp, 287
general resonance curve, 229
generators, 2, 148
  function generator, 148

germanium, diodes, 36
graph of resistance, 12–14

H

half power frequencies, 219
half power points, 219
half-wave rectifier, 352
Hartley method, 304
Hartley oscillator, 314–315
high pass filter experiment, 174–180
high Q circuit, 227
Hill, Winfield, 378
holes, 2, 36
Horowitz, Paul, 378

I

I_B, 80
  calculating, 112–113
  value, 111
I_c, 80
  load current, 108
IC (integrated circuit), 284
  op-amps, 285
I_{DSS} (saturation current), 139
impedance
  calculating, 169
  inductor and capacitor, calculating, 215
  internal impedance, 299
in phase, 331
inductor
  AC circuits, 156–158
  and capacitor in series, 208–218
  sine waves, 191
  voltage divider, 190
input resistance, 249
internal impedance, 299

J

JFET common source amplifier, 278
JFET (junction field effect transistors), 71, 97, 241
  as amplifier, 275–284
  amplifying AC signals, 276
  biasing circuit, 275
  experiment, 138–142
  forward transfer admittance, 280
  gate voltage, 99
  N-channel, 97
    operating, 99
  P-channel, 97, 99
  semiconductor material, 97
  switches, 137
  terminals, 97
  transconductance and, 280
junction field effect transistors. *See* JFET (junction field effect transistors)

K

KCL (Kirchhoff's current law), 19
  KVL and, 19
kilohm, 11
knee region, 44
knee voltage, 45, 46
KVL (Kirchoff's voltage law), 16
  KCL and, 19

L

LC circuit, 301
level DC, 358–373
limiting voltage, 45
line, 338
load, R_C, 108
load current, calculating, 110
load line, 245
load resistance, 249
low power carbon composition resistors, 10
low Q circuit, 228

M

magnet field, current flow and, 234
magnetically generating electric current, 2
mechanical switches, 20
  voltage drop, 40
megohm, 12

metal oxide silicon field effect transistors. *See* MOSFET
microampere, 11
milliampere, 11
MOSFET (metal oxide silicon field effect transistors), 71
Muir, Nancy, 378

N
N-channel JFET, 97
N type region, 36
negative feedback, 294–295
nonlinear regions, 246
notch filter, 222
NPN transistor, 75–76, 82

O
OFF transistor
  characteristics, 96
  resistor, 115
  resistor values, 116
Ohm’s law, 4–6
ON transistor
  collector voltage, 109
  turning on, 108–114
op-amp (operational amplifier), 241, 284–288
  gain, 287
operational amplifier, 284–288
oscillators, 233–236, 293–303
  amplifier, 293
  Armstrong oscillator, 316
  coil, 317
  Colpitts oscillator circuit, 308–313
  components, 293
  design, 316–320
  external input, 308
  feedback connections, 293
  Hartley oscillator, 314–315
  sine wave and, 235
  troubleshooting, 320–325
out of phase, 331
output impedance, 265
output signal, peak-to-peak value, 265
output voltage
  attenuated, 172
  calculationg, 168
  determining, 229
  resonant frequency and, 214
  waveform
    lagging, 182
    leading, 182

P
P type region, 36
peak (p) voltage, 150
peak-to-peak (pp) voltage, 150
perfect diode, 39
  V-I curve, 55
phase
  in, 331
  out of, 331
phase shift, RL circuit, 197–198
phasor diagram, 184
photovoltaic generation of electrons, 2
piezoelectrical generation of electric current, 3
PIV (peak inverse voltage), 57
PN junction, 36
  direction of flow, 36
PNP transistor, 75–76, 80, 82
positive feedback, 295–296
power, 8–10
  formula for, 8–9
  watts and, 8
power ratings, 10
power supply circuits, 347
  (peak-to-peak) voltage,D
    150
primary time measurement, sine waves, 151
PRV (peak reverse voltage), 57

Q
Q, 219
  calculating, 224
  high Q circuit, 227
  low Q circuit, 228

R
R_1, biasing and, 257
radio bandwidth, 222
range of frequencies, 221
R_B, 82
  calculating, 111–112, 113
  current values, 108
  turning transistor ON, 108
  voltage drop, 111
R_C, 84
  turning transistor ON, 108
RC circuit, phase shift, 180–186
R_E, biasing and, 257
reactance, 154
  capacitors, 166
rectification, 352
  full-wave rectifier, 355
  half-wave rectifier, 352
rectifier, 35
resistance, 154
  calculating total, 169
  graph of resistance, 12–14
resistors
  AC circuits, 152–154
  capacitors and, 186–190
  low power carbon composition, 10
  OFF transistor, 115
  in parallel, 7–8
  power ratings, 10
  in series, 6–7
  in series, 167–174
  values, OFF transistor, 116
resonance, 158–160
resonant circuits
  capacitor and inductor in series, 208–218
  half power freqencies, 219
  output curve, 218–232
resonant frequency, net reactance of inductor and capacitor and, 214
reverse biased diode, 39
  open switches and, 40
R_F (feedback resistor), 287
R_{IN} (input resistance), 249
RL circuit, phase shift, 197–198
R_L (load resistance), 249
RLC circuit, 208
  impedance, calculating, 209
  reactance, calculating, 209
rms (root mean square) voltage, 150
root mean square (rms) voltage, 150

S
saturation, 94, 140
saturation current (I_{DSS}), 139
saturation point, 246
semiconductor, 35
series
  capacitors in, 167–174
  resistors in, 167–174
silicon
  diodes, 36
  transistor, 111
sine wave, 147
  cycle, 148, 151
  duration, 151
  inductor, 191
  as input, 167
  oscillation and, 235
  as output, 167
  p voltage, 150
  pp voltage, 150
  primary time measurement, 151
  producing, 148
  rms voltage, 150
  signals, primary coils, 330
  zero axis, 149
single pole double throw switch, 20
single pole single throw switch, 20
small currents, 11–12
smoothing pulsating DC, 358–373
solar cells, 2
switches, 20–22

Zener effect, 58

United States Patent [19]

Gundlach

[11] **Patent Number: 4,595,852**

[45] **Date of Patent: Jun. 17, 1986**

[54] **ELECTROSTATIC GENERATOR**

[76] Inventor: **Robert W. Gundlach,** 2434 Turk Hill Rd., Victor, N.Y. 14564

[21] Appl. No.: **599,199**

[22] Filed: **Apr. 11, 1984**

[51] **Int. Cl.^{4}** **H02N 1/00**

[52] **U.S. Cl.** **310/309**

[58] **Field of Search** 310/308-310

[56] **References Cited**

[57] **ABSTRACT**

A novel induction-type electrostatic generator is disclosed in which moving electrodes are transported back and forth between two Faraday cages. Each moving electrode, once enclosed by a cage, is contacted to the cage, then separated by more than the sparking distance before making electrical connection to the opposite moving electrode or to ground. In this way, charge opposite in polarity but proportional in magnitude to the charge on each cage, is induced in each moving electrode and carried into and imparted onto the next cage, progressively elevating the cage potentials until the corona or arcing limits are reached. Initiation of charging is spontaneous, deriving from inevitable statistical imbalances in nature.

ELECTROSTATIC GENERATOR

BACKGROUND OF THE INVENTION

This invention relates to electrostatic generators, and more particularly to an improved induction-type electrostatic generator that is efficient, compact, and inexpensive, in which electrodes are transported back and forth between two Faraday cages.

The Greeks were the first to record observations of static electricity several thousand years ago. They discovered that amber, when rubbed vigorously with fur or fabrics under dry conditions, takes on electrostatic charge. In fact, the Greek word for amber, "electron", has become the root of many of our words relating to electricity.

It was not until about 1660 that the first electrostatic generator was invented. Otto von Guericke of Magdeburg, Germany showed electrostatic sparks could be produced by spinning and rubbing a dry sulfur globe. In this device, high potentials were developed by friction, or triboelectric charging. More than 200 years passed before James Wimshurst invented the first reliable induction-type generator, called the "influence machine" at the time (1878). This involved two insulating discs sliding against each other as they rotated in opposite directions on a common axis. Attached to these oppositely rotating plates were metal sectors into which charges are induced and carried to a capacitor for storage. The metal sectors continue inducing opposite charges in each other and carrying the charges to the appropriate ends of the capacitor, gradually building up the potentials of the capacitor until sparking voltages are reached. Wimshurst built many such machines, some with oppositely rotating discs more than two meters in diameter. The only substantial application of the Wimshurst generator appears to have been to operate the early X-ray tubes.

Then, in 1937, Robert Van de Graaff invented a belt-type generator in which an insulating belt, sometimes carrying conducting elements, transported charges into a giant conducting sphere, or "Faraday cage", to generate, in some cases, over a million volts. Van de Graaff charged the moving belt by spraying corona charge onto it or, alternatively, by frictionally charging it.

In the 1960's Prof. A. D. Moore designed an induction-type generator for instructional purposes. This is the simplest of the prior art generators to understand, and works purely by induction, requiring neither corona nor frictional charging means to produce the potential differences. FIG. **1** is a schematic diagram of Moore's "Dirod" generator, which he described in his book "Electrostatics", (Doubleday, Garden City, NJ, 1968; a Doubleday Anchor Book). In this generator, rods $\mathbf{20}_{(1 \rightarrow N)}$ are rotated between two collector electrodes, **22** and **24**. Each rod makes momentary electrical contact to collectors **22** and **24** through flexible conducting brushes **23** and **25**, respectively, as insulating disk **26** is rotated counterclockwise about its center. Just above and below rotating disc **26** are supported conducting rods **28** and **30**, called "inductors", electrically connected to collector electrodes **22** and **24**, respectively. At the point of nearest approach to each inductor, each of the rods $\mathbf{20}_n$ is momentarily contacted, one at a time, to ground or to the opposite rod $\mathbf{20}_{(n+N/2)}$ through flexible conducting brushes **29** and**31**, respectively. Any incipient charge or potential difference between collector electrodes **22** and **24** will induce opposite charges in those rods $\mathbf{20}_n$ and $\mathbf{20}_{(n+N/2)}$ adjacent the inductors **28** and **30**. For example, if we assume that, of the many billions of electrons in each of the collector electrodes, there is a slight excess in collector **22**, then collector **24** will be slightly positive relative to collector **22**. Inductor **28** will therefore induce positive charges in each rod $\mathbf{20}_n$ as it is grounded in its proximity to inductor **28**. At the same time inductor **30** induces negative charges in each rod $\mathbf{20}_{(n+N/2)}$ when grounded next to inductor **30**. As the charged rods separate from inductor rods **30** and **28**, their potentials increase so that part of the induced charges flow off to the collector plates **22** and **24**, increasing their negative and positive potentials, respectively. As the potentials of the collector electrodes increase, so the charges induced in rods $\mathbf{20}_n$ by inductors **28** and **30** increase, quickly driving the collector electrodes to their maximum values. Once charging begins it will be seen how the potential difference grows at a progressively increasing rate. The statistical imbalance of nature insures that the initial imbalance can always be depended on. (To understand how the instability builds on itself, we need only understand why a sharpened pencil cannot be balanced long on its point; the restoring force is negative, and is proportional to the degree of imbalance.) Professor Moore's Dirod generator routinely produces 60 to 70 kV, depending on the spacing of the rods **20** from inductors **28** and **30**, since air breakdown (arcing) occurs at about 30 kV per cm for gaps larger than a few millimeters. This generator is not entirely satisfactory for manufacturing as an educational toy or for use for demonstrations because it is relatively complicated and expensive to produce and complex to understand.

SUMMARY OF THE INVENTION

Accordingly, the present invention provides a simplified electrostatic generator for an educational toy. Also, the present invention provides an electrostatic generator that is more efficient, more affordable, more rugged, and easier to understand for teaching purposes and experimental uses than prior art devices.

The foregoing and other features of the instant invention will be more apparent from a further reading of the specification and claims and from the drawings, in which:

FIG. **1** is a schematic plan view of a prior art generator.

FIG. *2a* is a schematic plan view of the preferred embodiment of the present invention.

FIG. *2b* is an isometric view of the preferred embodiment of the present invention.

FIG. **3** shows an alternative embodiment of the present invention that employs a single mobile electrode.

While the invention will be described hereinafter in connection with a preferred embodiment and an alternative embodiment, it will be understood that it is not intended to limit the invention to those embodiments. On the contrary, it is intended to cover all alternatives, modifications, and equivalents as may be included within the spirit and scope of the invention as defined by the appended claims.

DESCRIPTION OF THE PREFERRED EMBODIMENT

In the pesent invention the induction-type generator has been simplified and made much more efficient by combining each pair of collector and inductor electrodes into a single Faraday cage, as shown in FIGS. 2*a* and 2*b*. As Faraday taught, and Van de Graaff put to use, by enclosing a charged object in a conducting cage, the potential of the whole cage is increased as if all the charges were placed onto the cage, itself. In fact, if the enclosed charged object is conducting and makes conductive contact with the cage, all charges do, indeed, flow from the charged object onto the surrounding "Faraday cage".

In this example only two rotor electrodes **40***a* and **40***b* are shown. In fact, any even number can be used, within practical space limitations. An odd number could be used if external ground is provided during charge induction. With an even number of rotor electrodes, contacts **48** and **50** can be connected to each other, instead of to external ground, to induce electrons from one rotor electrode to the other. Rotor electrode **40***a* is transported by clockwise rotation from one cage **42**, to the other cage **44**, making sequential contact first with the surrounding, or enclosing case, through contact post **43**, then, after adequate separation from contact post **43**, making momentary contact with ground or the opposite rotor electrode **40***b* through contact posts **50** and **48**, whereby charges opposite to those on the enclosing cage are induced on each rotor plate and then transported to the opposite cage through brushes **49** and **51**. This results in a progressive build-up of opposite electrostatic potentials on collector cages **42** and **44**. Assuming thin, flat rotor plates **40**, the capacitance of each rotor plate **40** to the shell or cage **42** when the plate is totally enclosed by the cage is given by:

$$C = \frac{K\epsilon_0 A}{t}$$

where C is capacitance, K is the dielectric constant of the medium (K=1 for air), ϵ_o is the permittivity of space ($\epsilon_o = 9\times10^{-12}$), A is the area of the surface of the rotor plate, and t is the distance between the rotor plate **40** and the inner surface of the shell **42**. Each plate carries a charge q out of one shell and into the other shell every half rotation, equal to:

$$q = CV.$$

It is possible, then, to calculate the current that can be supplied by this generator for any specified values of rotor plate area A, distance t between the rotor plate **40** and the parallel surface of the cage **42**, and speed of rotation of the rotor plates.

$$i = \frac{dq}{dt} = 4\omega CV$$

where ω is the spin velocity in rotations per second. For example, an area of 100 cm^2 on each face of the rotor plate ($A = 2\times10^{-2}m^2$), and a plate-to-cage spacing of 1 cm ($t = 10^{-2}m$), and a spin velocity of ten rotations per second, gives a generator current of:

$$i = 40\ CV = 40 \times \left(\frac{9\times10^{-12}\times2\times10^{-2}}{10^{-2}}\right) V = 7.2\times10^{-10}\ V \text{ amperes}$$

Clearly, then, current is very low for very low voltages, but builds exponentially with time, the initial voltage build-up can be expedited by placing a charged object on one of the cages. Once the maximum potential of, say, 20 kV is reached, the generator of this example of the present invention would produce a current of:

$$i = 1.4\times10^{-5} \text{ amperes, or about } 14\ \mu A$$

FIG. **3** shows another embodiment of the present invention. Here a single mobile electrode **60** is mounted on a hinge **61** and swings reciprocally between Faraday cages **62** and **64**. In this figure, the top plate of each cage **62** and **64** has been removed for clarity. Movable electrode **60** enters either cage **62** or **64**, makes conducting contact with said cage, separates from said conducting contact by more than the sparking distance (1 cm for every 30 kV), and then makes the electrical contact to ground while it is still enclosed by said cage. During grounding, charges opposite to the charge on the enclosing cage are induced in electrode **60**, and these are transported by movable electrode **60** into and deposited onto the opposite Faraday cage. Swinging contacts **63** and **65** prevent electrical contact between movable plate **60** and ground during entry of plate **60** to each cage, while they insure contact with conducting edges **64** and **66** during exit, while plate **60** is still fully enclosed within the associated Faraday cage. Since the charges induced on movable plate **60** are proportional to the charges on the enclosing cage, repeating the cyclic process produces progressively increasing potentials until corona or sparking limits are reached.

In summary, the advantages of the electrostatic generator of the present invention are its elegant simplicity for construction, for providing a simple understanding for the student, its ruggedness of design for portability without damage, affordability of cost, and its high efficiency derived by maximizing the rotor area and thus capacitance, for a given spacing, the spacing determining the inherent limitation of voltage imposed by dielectric breakdown of air or other fluid medium in which the generator is operated. If we wish to develop potentials of 30 kV operating in air, for example, the spacing of rotors **40** to cages **42** must be at least one cm, since the dielectric breakdown of air for such gaps is 30 kV/cm.

While the principles described herein have been described by the example of FIGS. 2*a*, 2*b*, and **3**, it should be understood that the concepts disclosed can be embodied in various mechanical designs without departing from the teachings of this invention and may come within the scope of the following claims.

What is claimed is:

1. A spontaneous non-frictional electrostatic induction-type generator, comprising:

(a) two Faraday cages:

(b) electrode means, substantially surrounded by and mounted for rotary movement relative to said Faraday cages in order to enable said Faraday cages to serve alternately as both the inductor and collector electrodes: and

(c) flexible contact means comprising a single set of brushes mounted to said rotary electrode means so as to extend by centrifugal force into electrical contact with said Faraday cages, then, after separating from each cage by more than the sparking distance, momentarily contacting each said flexible contact means to ground or to opposite ends of a conductor connecting said flexible contact means to each other to progressively charge said Faraday cages.

2. The spontaneous non-frictional electrostatic induction-type generator of claim **1**, wherein said electrode means comprises an even number of movable electrodes, and flexible contact means mounted for centrifugal extension to make momentary electrical contact separately to each cage; then, after separating from each cage by more than the sparking distance, momentarily connecting said movable elctrodes to each other.

3. The method of claim **1**, wherein an even number of rotary movable electrodes is provided, and means, mounted for extension by centrifugal force, is provided for contacting said rotary movable electrodes separately to each Faraday cage, then, after separating from each cage by more than the sparking distance, momentarily connecting said rotary movable electrodes to each other.

4. The spontaneous electrostatic induction-type generator of claim **1**, wherein said electrode means comprises a plurality of movable electrodes.

5. A method of generating high electrostatic potentials using a spontaneous, non-frictional electrostatic induction-type generator comprising the steps of:

(a) providing two Faraday cages;

(b) providing electrode means substantially surrounded by and mounted for rotary movement relative to said Faraday cages; and

(c) providing flexible contact means mounted to said rotary electrode means so as to extend by centrifugal force into electrical contact with each cage separately, then, after separating from each cage by more than the sparking distance, momentarily contacting to ground or to a neutral conductor, in order to progressively charge said Faraday cages.

(57) **ABSTRACT**

This invention relates to a spacecraft propulsion system utilizing a rotating octagon of trapezoidal electrically charged flat panels to create an electric dipole moment that generates lift on the hull. On the interior side of each panel are electrostatically charged rods which produce a planar electric field that emerges from holes in the panel to form an ellipsoidal potential energy bubble on the outside of the hull. The rotating hull dipole moment generates a magnetic moment which, together with the magnetic field gradient developed by the rotating electric field of the electrostatically charged panels, produces said lift force. The potential energy field is enhanced by using a double cladding of hull material with different ranges of permittivities.

ELECTRIC DIPOLE MOMENT PROPULSION SYSTEM

BRIEF SUMMARY OF THE INVENTION

[**0001**] The invention, which is the object of my present application, is a spacecraft utilizing trapezoidal electrostatically charged flat plate panels which form a pyramidal hull. A panel contains three holes each of which produces a potential energy ellipsoidal bubble that creates an electric dipole moment. The rotation of the hull generates a magnetic moment and a magnetic field gradient in the vertical direction that produces a lift force on the spacecraft.

[**0004**] *Classical Electrodynamics,* John David Jackson, Chapter 3.12, *Mixed Boundary Conditions; Conducting Plan with a Circular Hole.*

BACKGROUND OF THE INVENTION

[**0005**] I was reading Dr. Jackson's book about the formation of a potential energy bubble by a hole in a conducting plane, a picture of which is shown on page 134 of his book. It turns out that this bubble creates an electric dipole moment from which it is possible to get a magnetic moment. Then I realized that a rotating tilted hull having a velocity gradient would produce a magnetic field gradient in the vertical direction. This combination produces a lift force on the spacecraft.

[**0006**] I did quite a number of computer simulations of the bubble using an electromagnetic simulation software program. I found that the hole in the plate doesn't produce a very large potential energy bubble. So I created another simulation where the hole protrudes out of the plate in an ellipsoidal shape. This produces a much larger field. I then found that using a double cladding, in which each layer has a different permittivity, confined the field to the outside of the hull for even better results.

[**0007**] The planar potential energy is created by a grid of electrically charged wires or rods running the length of each panel. As shown by Feynman, the circular potential energy from each rod very quickly sums to form a flat sheet of energy which emerges from the hole to form said potential energy bubble.

SUMMARY OF THE INVENTION

[**0008**] The invention relates to a spacecraft utilizing a rotating octagon of trapezoidal electrically charged flat plate panels to form a hull in the shape of a pyramid. Each panel has three protruding ellipsoidal bubbles that produce an electric dipole moment from a planar potential energy field created by a group of charged rods parallel to the panel. Because the panels are tilted and the hull is rotating, there is a tangential velocity gradient in the vertical direction. This creates the magnetic moment. Because the hull rotates, the radial electric field produces a magnetic field gradient in the vertical direction. This combination of magnetic moment and magnetic field gradient produces a lift force on the hull of the spacecraft.

[**0009**] On the underside of each panel is a group of high voltage electrically charged rods which run parallel to the panel. These wires or rods produce a planar electrical potential field underneath the holes in the panel. This potential energy field then bubbles out of the holes in the panel to create a large ellipsoidal potential energy field above the hull. The potential energy bubble carries an electric dipole moment which when rotated with the hull generates a magnetic moment in the vertical direction.

DETAILED DESCRIPTION OF THE INVENTION

[0035] 1. Referring to **FIG. 1**, the spacecraft is a rotating octagon of trapezoidal electrostatically charged flat panels which form a closed hull (A). Each panel has three ellipsoidal domes (B) of varying size centrally located along the major length of the panel. The purpose of the dome is to create a large ellipsoidal potential energy bubble over the hull which develops an electrical dipole moment. Because the hull is rotating, a magnetic moment is created in the vertical direction. A magnetic field gradient created by the rotating electric field on the hull in combination with said magnetic moment produces a lift force on the hull.

[0036] 2. Referring to **FIG. 2**, the trapezoidal hull panel (A) contains three ellipsoidal holes (E). A group of wires or rods (C) running parallel to and just underneath the panel are electrically charged to a high voltage at the end terminals (B). Said rods produce a planar potential energy field (D) just under the holes in the panel. The field emerges from the holes in the shape of an ellipsoidal bubble and is amplified by an ellipsoidal dome (F) on the outside of the hull.

[0037] 3. Referring to **FIG. 3**, the group of parallel rods (A) are given a linear charge λ in units of charge per meter. The electric field E developed by the rod is the linear charge divided by the circumference of a circle of radius r around the wire times the permittivity ϵ of space. The analysis of this arrangement shows that within a few grid width spacings, the potential energy field ϕ has become planar (B) in the z-direction given by the equation in **FIG. 4**.

[0038] 4. The forthcoming analysis is done in cylindrical coordinates, **FIG. 5**.

[0039] 5. Referring to **FIG. 6**, the ellipsoidal potential energy (B) emerges through the hole in the panel plate (A). In doing so it creates an electrical dipole moment (C) shown by the arrow normal to the hole area. The theoretical analysis matched a computer simulation of this emergence of the bubble (B) through plate (A), as shown in **FIG. 7**.

[0040] 6. Because the bubble has the shape of an ellipse, the centroid of the bubble would be four thirds the radius a divided by π as given in **FIG. 8**. The electric dipole moment is then given as the charge times said centroid. The charge of the hole is equal to the permittivity times the electric field emerging from the hole times the area of the hole as seen in the equation of **FIG. 9** with the units of charge, **FIG. 10**.

[0041] 7. The electric dipole moment is said centroid times said charge, as seen in the equation given in **FIG. 11** and having units of coulomb-meter. Notice that the electric dipole moment p times a velocity v is equal to a magnetic moment μ which is what creates the lift force on the hull as shown in the next **FIG. 12**.

[0042] 8. The rotating hull creates the electric dipole moment velocity so that the entire hull develops a magnetic moment. In tensor notation, **FIG. 13**, the magnetic moment is in the vertical direction because there is a radial component of the electric dipole moment times the velocity. The velocity is the radius r in the radial direction times the angular velocity in the z-direction.

[0043] 9. The force on the hull is the gradient of the dot product of the magnetic moment with the magnetic B field given in equation **FIG. 14**.

[0044] 10. By electrically charging the hull of the vehicle, a radial electric field is produced. By rotating the hull, the radial electric field changes with time. Thus Maxwell's equations will involve the curl of the magnetic field in the radial direction because the radial electric field is varying with time. Maxwell's equation is seen in **FIG. 16**.

[0045] 11. The cross product involves the magnetic field in the theta direction which is zero. The electric field varies with time as shown in **FIG. 17**. Substituting the derivative of the electric field and integrating with respect to angle theta gives the vertical magnetic field as the tangential velocity times the radial field divided by the speed of light squared (**FIG. 18**).

[0046] 12. Now the force on the hull is the gradient of the magnetic moment times the magnetic field. In the equation for the magnetic field, the only available variable to work with in order to get a gradient is the velocity. To me this was the surprise in this invention. The velocity had to be a function of the height of the hull (**FIG. 19**) which meant that the hull had to be in the shape of a pyramid, **FIG. 20**. Using eight flat sides keeps the radial electric field pointing in the same direction in each panel. Each panel has three domes to produce the magnetic moment for a total of 24 magnetic moment generators.

[0047] 13. Referring to **FIG. 21**, the electric dipole moment (A) points in the radial direction, the rotating hull produces a tangential velocity (B), and the result is a magnetic moment (C) along the panel.

[0048] 14. Because the magnetic moment is parallel to the panel, there are vertical and radial components of the magnetic moment. The vertical magnetic moment creates the dot product with the magnetic field gradient, which is equal to the lift force, as depicted in **FIG. 22**.

[0049] 15. **FIG. 23** shows a cross-section of the dome (A) and the plate hole (B) with double cladding to enhance the field as determined by computer simulation. The upper cladding (D) has a low relative permittivity in the range of 2 to 40, and the lower layer has a high relative permittivity in the range of 1200 to 4000. This dome and cladding configuration creates a much larger electric dipole moment compared to a hole in the plate, comparing **FIG. 23** to that of **FIG. 7**. The wavy lines are the equi-potential energy lines from the dome (C) and the upper layer (B) and the lower level (A).

What I claim as my invention is:

1. A spacecraft having a rotating octagon of trapezoidal electrostatically charged flat panels which form a closed hull in the shape of a pyramid.

2. Said panels each having three holes covered by three ellipsoidal domes of varying size centrally located along the major length of the panel.

3. A grid of high voltage electrostatically charged rods located on the interior side of each panel such that a planar potential field is produced parallel to and under each hole of said panel.

4. Said domes and holes in panel produce an ellipsoidal potential energy field carrying an electric dipole moment on the outside of the hull.

5. Said rotating hull together with electric dipole moment produce a magnetic moment in the vertical direction.

6. Said rotating charged hull produces an electric field in the radial direction which generates a corresponding magnetic field gradient in the vertical direction proportional-to the velocity gradient of the sloping panels of the hull.

7. Combined magnetic moment and magnetic field produce lift on the hull.

8. Dome material and surface layer cladding having different permittivities which enhance said electric dipole moment.

9. Use of magnetic vortex generator to bring in low density hyperspace energy in order to increase the field strengths as described in my patent applications Magnetic Vortex Wormhole Generator and Magnetic Vortex Generator.

ELECTRIC DIPOLE MOMENT PROPULSION SYSTEM

BRIEF SUMMARY OF THE INVENTION

[0001] The invention is a spacecraft utilizing trapezoidal electrostatically charged flat plate panels which form a pyramidal hull. A panel contains three holes each of which produces a potential energy ellipsoidal bubble that creates an electric dipole moment. The rotation of the hull generates a magnetic moment and a magnetic field gradient in the vertical direction that produces a lift force on the spacecraft.

BACKGROUND OF THE INVENTION

[0002] It is known from electrodynamics that a hole in a conducting plane forms a potential energy bubble. This bubble creates an electric dipole moment from which it is possible to develop a magnetic moment. A rotating tilted hull produces a velocity gradient that generates a magnetic field gradient in the vertical direction. This combination produces a lift force on the spacecraft. A very large potential energy bubble is produced provided that the hole protrudes out of the plate in an ellipsoidal shape. Furthermore, a double cladding, in which each layer around the hole has a different permittivity, confines the field to the outside of the hull for even better results.

[0003] The planar potential energy is created by a grid of electrically charged wires or rods running the length of each panel. A circular potential energy from each rod very quickly sums to form a flat sheet of energy which emerges from the hole to form the potential energy bubble.

SUMMARY OF THE INVENTION

[0004] The invention relates to a spacecraft utilizing a rotating octagon of trapezoidal electrically charged flat plate panels to form a hull in the shape of a pyramid. Each panel has three protruding ellipsoidal bubbles that produce an electric dipole moment from a planar potential energy field created by a group of charged rods parallel to the panel. Because the panels are tilted and the hull is rotating, there is a tangential velocity gradient in the vertical direction. This creates the magnetic moment. Because the hull rotates, the radial electric field produces a magnetic field gradient in the vertical direction. This combination of magnetic moment and magnetic field gradient produces a lift force on the hull of the spacecraft.

[0005] On the underside of each panel is a group of high voltage electrically charged rods which run parallel to the panel. These wires or rods produce a planar electrical potential field underneath the holes in the panel. This potential energy field then bubbles out of the holes in the panel to create a large ellipsoidal potential energy field above the hull. The potential energy bubble carries an electric dipole moment which when rotated with the hull generates a magnetic moment in the vertical direction.

DETAILED DESCRIPTION OF THE INVENTION

[0017] 1. Referring to **FIG. 1**, the spacecraft is a rotating octagon of trapezoidal electrostatically charged flat panels which form a closed hull (A). Each panel has three ellipsoidal domes (B) of varying size centrally located along the major length of the panel. The purpose of the dome is to create a large ellipsoidal potential energy bubble over the hull which develops an electrical dipole moment. Because the hull is rotating, a magnetic moment is created in the vertical direction. A magnetic field gradient created by the rotating electric field on the hull in combination with the magnetic moment produces a lift force on the hull.

[0018] 2. Referring to **FIG. 2**, the trapezoidal hull panel (A) contains three ellipsoidal holes (E). A group of wires or rods (C) running parallel to and just underneath the panel are electrically charged to a high voltage at the end terminals (B). The rods produce a planar potential energy field (D) just under the holes in the panel. The field emerges from the holes in the shape of an ellipsoidal bubble and is amplified by an ellipsoidal dome (F) on the outside of the hull.

[0019] 3. Referring to **FIG. 3**, the group of parallel rods (A) are given a linear charge λ in units of charge per meter. The electric field E developed by the rod is the linear charge divided by the circumference of a circle of radius r around the wire times the permittivity ϵ of space. The analysis of this arrangement shows that within a few grid width spacings, the potential energy field ϕ due to the electric field E_0 has become planar (B) in the z-direction given by the equation

$$\phi=-E_0 z$$

[0020] 4. Referring to **FIG. 4**, the following analysis is done in cylindrical coordinates {r,θ,z}.

[0021] 5. Referring to **FIG. 5**, the ellipsoidal potential energy (B) emerges through the hole in the panel plate (A). In doing so it creates an electrical dipole moment (C) shown by the arrow normal to the hole area.

[0022] 6. Referring to **FIG. 6**, the bubble (B) emerges through plate (A).

[0023] 7. Because the bubble has the shape of an ellipse, the centroid y of the bubble would be four thirds the radius a divided by π as given by

$$\overline{y}_{ellipse} = \frac{4}{3}\frac{a}{\pi}$$

[0024] The electric dipole moment is then given as the charge q times the centroid y. The charge of the hole is equal to the permittivity E times the electric field E emerging from the hole times the area of the hole of radius a

$$q = \varepsilon_0 E\pi a^2 \frac{\text{coul}^2}{\text{m}^2\ \text{newton}}\frac{\text{newton}}{\text{coul}}\ \text{m}^2 = \text{coul} = \text{charge}$$

[0025] 8. The electric dipole moment p is the centroid y times the charge q

$$p = qy = \varepsilon_0 E\pi a^2 \frac{4}{3}\frac{a}{\pi} = \frac{4}{3}\varepsilon_0 E a^2\ \text{coul}\cdot\text{meter}$$

[0026] The electric dipole moment p times the hull velocity v is equal to a magnetic moment μ which is what creates the lift force on the hull

$\mu = pv$ amp·m^2

[0027] 9. The rotating hull creates the electric dipole moment velocity so that the entire hull develops a magnetic moment. In tensor notation, the magnetic moment μ is in the vertical z-direction because there is a radial component of the electric dipole moment times the velocity. The velocity is the radius r in the radial direction times the angular velocity ω in the z-direction

$\mu^z = p_r x^r \omega^z$

[0028] 10. The force F on the hull is the gradient of the dot product of the magnetic moment μ with the magnetic B field

$F = \nabla(\mu \cdot B)$

[0029] 11. By electrically charging the hull of the vehicle, a radial electric field is produced. By rotating the hull, the radial electric field changes with time. Thus Maxwell's equations will involve the curl of the magnetic field in the radial direction because the radial electric field is varying with time

$$(\nabla \times B)_r = \frac{1}{c^2}\frac{\partial E_r}{\partial t}$$

[0030] 12. The cross product involves the magnetic field in the theta direction which is zero

$$\frac{1}{r}\frac{\partial B_z}{\partial \theta} - \frac{\partial B_\theta}{\partial z} = \frac{1}{c^2}\frac{\partial E_r}{\partial t} = \frac{1}{r}\frac{\partial B_z}{\partial \theta}$$

[0031] Substituting the derivative of the electric field E

$E_r = E_0 e^{i\omega t}$

[0032] and integrating with respect to angle theta gives the vertical magnetic field B as the tangential velocity v times the radial electric field E divided by the speed of light c squared

$$B_z = \frac{v}{c^2}E_r$$

[0033] 13. The force on the hull is the gradient of the magnetic moment μ times the magnetic field B. In the equation for the magnetic field, the only available variable to work with in order to get a gradient of the magnetic field comes from the velocity.

$$\frac{dB_z}{dz} = \frac{E_r}{c^2}\frac{dv}{dz}$$

[0034] 14. Referring to **FIG. 7**, because the hull is in the shape of a pyramid, the velocity is a function of the height z of the hull. Using eight flat sides keeps the radial electric field pointing in the same direction in each panel. Each panel has three domes to produce the magnetic moment for a total of 24 magnetic moment generators.

[0035] 15. Referring to **FIG. 8**, the electric dipole moment (A) points in the radial direction, the rotating hull produces a tangential velocity (B), and the result is a magnetic moment (C) along the panel.

[0036] 16. Referring to **FIG. 9**, because the magnetic moment is parallel to the panel, there are vertical and radial components of the magnetic moment. The vertical magnetic moment creates the dot product with the magnetic field gradient, which is equal to the lift force.

[0037] 17. **FIG. 10** shows a cross-section of the dome (A) and the plate hole (B) with double cladding to enhance the field. The upper cladding (D) has a low relative permittivity in the range of 2 to 40, and the lower layer has a high relative permittivity in the range of 1200 to 4000.

[0038] 18. Comparing **FIG. 11** to **FIG. 7**, this dome and cladding configuration creates a much larger electric dipole moment compared to a hole in the plate. The wavy lines are the equi-potential energy lines from the dome (C) and the upper layer (B) and the lower level (A).

I claim:

1. A spacecraft propulsion system comprising:

a rotating octagon of trapezoidal electrostatically charged flat panels which form a closed sloping hull in the shape of a pyramid;

panels each having three holes covered by three ellipsoidal domes of varying size centrally located along the major length and axis of each panel; and

a grid of high voltage electrostatically charged rods located on the interior side of each panel such that a planar potential field is produced parallel to and under each panel hole.

2. The domes, holes and rotating charged hull of method 1 producing:

an ellipsoidal potential energy field emerging from the holes and generating an electric dipole moment on the outside of the hull;

a magnetic moment in the vertical direction due to the rotating electric dipole moment; and

a rotating electric field in the radial direction which generates a corresponding magnetic field gradient in the vertical direction proportional to the velocity gradient of the sloping panels of the hull.

3. A lift force on the spacecraft hull generated by:

the magnetic moment times the gradient of the magnetic field in the vertical direction; and

a dual surface layer hull cladding having different permittivities which enhance the electric dipole moment whereby the upper cladding has a low relative permittivity in the range of 2 to 40, and the lower layer has a high relative permittivity in the range of 1200 to 4000.

ELECTRIC DIPOLE SPACECRAFT

BRIEF SUMMARY OF THE INVENTION

[0001] This invention is a rotating spacecraft that utilizes four spherical conducting domes perturbing a uniform electric field in order to create a lift force by means of a magnetic moment times the gradient of a magnetic field.

BACKGROUND OF THE INVENTION

[0002] An electric dipole p is two electrical charges of opposite sign {q, −q} separated by a distance a.

$$p=qa=\text{coulomb}\cdot\text{meter}$$

[0003] If this dipole is moving with a velocity v, it produces a magnetic moment μ.

$$\mu = pv = qav = \text{coulomb meter}\frac{\text{meter}}{\text{sec}} = \frac{\text{coulomb}}{\text{sec}}\text{meter}^2 = IArea$$

[0004] The magnetic moment is equal to a current I circulating around an area. The magnetic field B has units of kilogram per second per charge coulomb.

$$B = \frac{\text{kg}}{\text{sec } coul}$$

[0005] The gradient of the magnetic field in the vertical direction z has units of

$$\frac{\text{dB}}{dz} = \frac{\text{kg}}{\text{sec } coul \text{ meter}}$$

[0006] This gradient interacting with a magnetic moment creates a force F measured in newtons.

$$F_z = \mu\frac{\text{dB}}{dz} = \frac{coul\ \text{m}^2}{\text{sec}}\frac{\text{kg}}{\text{sec } coul\ m} = \frac{\text{kg } m}{\text{sec}^2} = \text{newton}$$

[0007] In terms of vectors, the force is equal to

$$F=\nabla(\mu\cdot B)$$

which is the gradient ∇ of the dot product (·) of the magnetic moment with the magnetic field. This means that the magnetic moment has to be aligned with the field. The lift force on the spacecraft would then be the magnetic moment in the vertical z-direction μ_z times the magnetic field in the z-direction B_z. For constant magnetic moment, the gradient affects the magnetic field only, resulting in the same force equation

$$F_z=\nabla(\mu_z\cdot B_z)=\mu_z\nabla B_z$$

[0008] Referring to **FIG. 1**, the electric dipole has a positive charge q located on the z-axis at a distance a from the origin of the graph. A second negative charge −q is located at a distance −a from the origin. The positive charge produces an electrostatic potential ϕ_1 at a radius r_1 equal to the charge q divided by 4π times the permittivity of space ϵ_0

$$\varphi_1 = \frac{q}{4\pi\varepsilon_0}\frac{1}{r_1}$$

where the permittivity is linear capacitance, measured in farads per meter. The electrostatic potential has units of volts

$$\varphi = \frac{coul}{\left(\frac{\text{farad}}{\text{meter}}\right)}\frac{1}{\text{meter}} = \frac{coul}{\text{farad}} = \text{volt}$$

because the charge in coulombs held by a capacitor is equal to the capacitance, measured in farads, times the capacitor voltage. Because the second charge has the opposite sign, the potential ϕ_2 at a radius r_2 to the same point in space is

$$\varphi_2 = \frac{-q}{4\pi\varepsilon_0}\frac{1}{r_2}$$

[0009] The total potential ϕ at some point in space is equal to the sum of the two potentials, or

$$\varphi = \varphi_1 + \varphi_2 = \frac{q}{4\pi\varepsilon_0 r_1} - \frac{q}{4\pi\varepsilon_0 r_2} = \frac{q}{4\pi\varepsilon_0}\left[\frac{1}{r_1} - \frac{1}{r_2}\right]$$

[0010] As seen in the diagram, the point of space is a distance r from the origin. Using the law of cosines, radius r_1 can be written as

$$r_1 = (r^2 + a^2 - 2ar\cos(\theta))^{\frac{1}{2}} = r\left(1 + \left(\frac{a}{r}\right)^2 - 2\left(\frac{a}{r}\right)\cos(\theta)\right)^{\frac{1}{2}} = r(1 - 2xt + t^2)^{\frac{1}{2}}$$

where t is the ratio of the charge location over the radius, and x is cos(θ). The potential for positive charge q_1 can be written

$$\varphi_1 = \frac{q}{4\pi\varepsilon_0}\frac{1}{r_1} = \frac{q}{4\pi\varepsilon_0}\frac{1}{r}(1 - 2xt + t^2)^{-1/2}$$

[0011] Dropping the factor $q/4\pi\epsilon_0 r$, the square root can be expressed in terms of the Legendre polynomial P_n cos(θ) of the nth power

$$g(t, x) = (1 - 2xt + t^2)^{-1/2} = \sum_{n=0}^{\infty} P_n(x)t^n$$

where the absolute value of t is less than one. The polynomial coefficients of t^n can be obtained by using the binomial theorem to expand the generating function g(t,x) as

$$(1-2xt+t^2)^{-1/2}=\sum_{n=0}^{\infty}\frac{(2n)!}{2^{2n}(n!)^2}(2xt-t^2)^n$$

which evaluates to

$$\frac{0!}{2^0(0!)^2}(2xt-t^2)^0+\frac{2!}{2^2(1!)^2}(2xt-t^2)^1+\frac{4!}{2^4(2!)^2}(2xt-t^2)^2$$

$$1t^0+xt^1+\left(\frac{3}{2}x^2-\frac{1}{2}\right)t^2+\text{order}(t^3)$$

[0012] The first three Legendre polynomials are therefore

$$P_0=1$$

$$P_1=x$$

$$P_2=\frac{1}{2}(3x^2-1)$$

[0013] The electrostatic potential for both charges of the electric dipole is

$$\varphi=\frac{q}{4\pi\varepsilon_0}\frac{1}{r}\left\{\left(1-2\left(\frac{a}{r}\right)\cos(\theta)+\left(\frac{a}{r}\right)^2\right)^{-1/2}-\left(1+2\left(\frac{a}{r}\right)\cos(\theta)+\left(\frac{a}{r}\right)^2\right)^{-1/2}\right\}$$

[0014] The potential can be evaluated in terms of the Legendre polynomials as

$$\begin{aligned}\varphi&=\frac{q}{4\pi\varepsilon_0 r}\left[\sum_{n=0}^{\infty}P_n(\cos(\theta))\left(\frac{a}{r}\right)^n-\sum_{n=0}^{\infty}P_n(\cos(\theta))(-1)^n\left(\frac{a}{r}\right)^n\right]\\&=\frac{2q}{4\pi\varepsilon_0 r}\left[P_1(\cos(\theta))\left(\frac{a}{r}\right)+P_3(\cos(\theta))\left(\frac{a}{r}\right)^3+\dots\right]\end{aligned}$$

[0015] The first and most dominant term when the radius is much greater than location a is equal to

$$\varphi=\frac{2aq}{4\pi\varepsilon_0}\frac{P_1(\cos(\theta)0}{r^2}$$

which is the electric dipole potential and 2aq is the dipole moment

p=2aq

[0016] Now imagine a constant electric field E_0 which is perturbed by a conducting sphere of radius a. The unperturbed electrostatic potential outside the sphere would the negative of the electric field times the radius times the Legendre polynomial, or

$\Phi_1=-E_0rP_1$

[0017] The electrostatic potential perturbed by the charges is the voltage E_0a times the radius a times the a of the dipole moment times the Legendre polynomial divided by the radius squared

$$\varphi_2=E_0aaa\frac{P_1}{r^2}=E_0a^3\frac{P_1}{r^2}$$

[0018] The total potential outside the sphere is the sum of the two potentials equal to

$$\varphi=-E_0rP_1+E_0a^3\frac{P_1}{r^2}=-E_0P_1\left(r-\frac{a^3}{r^2}\right)=-E_0rP_1\left(1-\left(\frac{a}{r}\right)^3\right)$$

[0019] Referring to **FIG. 2**, the previously uniform electric field is shown perturbed by the neutral conducting sphere. The center of the sphere is taken as the origin and the z-axis is oriented parallel to the original uniform field.

[0020] The electric field induces a surface charge density σ on the sphere equal to the negative of the permittivity of space times the gradient of the electrostatic potential

$$\sigma=-\varepsilon_0\frac{\partial\varphi}{\partial r}|_{r=a}=3\varepsilon_0E_0\ \cos(\theta)$$

[0021] The electric field also induces an electric dipole moment on the sphere equal to the

$$p=\frac{qa}{r}\cdot\frac{2a^2}{r}=4\pi\varepsilon_0E_0a^3$$

with units of coulomb-meter. If this sphere is rotating around a central axis at a velocity v, it will create a magnetic moment μ equal to the dipole moment times the velocity.

μ=pv

with units of ampere-meter^2.

SUMMARY OF THE INVENTION

[0022] As shown in the preceding background section, a neutral conducting sphere placed in a uniform electric field will generate a magnetic moment when rotated around a central axis. The electric field can be created by two points charges of opposite sign separated by a distance between them.

[0023] Referring to **FIG. 3**, the spacecraft has a spherical cabin (A) to which are attached cone-shaped electrostatic towers (B,C) above and below the cabin along the direction of travel in the z-direction. Because the electric field goes from the positive charge to the negative charge, the tip of the lower tower has a positively charged electrode, and the upper tower has a negatively charged electrode. Four equally-spaced neutral conducting spheres (D) are connected to the cabin by non-conducting tubes (E). The tubes make an angle with the cabin such that the distance (CD) is greater than distance (DB). The angle θ of the tube with respect to the cabin can be seen in side view **FIG. 4**.

[**0024**] Referring to **FIG. 5**, the charges create a uniform spherical field between the towers. The conducting spheres perturb this field such that the electric field (E) points toward the upper tower in a manner similar to that shown previously in **FIG. 2**.

[**0025**] Referring to **FIG. 6**, the conducting sphere produces an electric dipole moment (A) pointing at an angle toward the upper tower.

[**0026**] Referring to **FIG. 7**, by the law of addition of vectors, the electric dipole $\bar{p}$ can be represented by two orthogonal vectors pointing in the vertical z-direction p_z and in the inward radial direction p_r.

[**0027**] Referring to **FIG. 8**, the hollow tube (A) connecting the cabin with the conducting sphere contains a spiral-wound electrical solenoid (B) which produces a magnetic field (C). This magnetic field B can be decomposed into two orthogonal vectors pointing in the vertical z-direction B_z and in the outward radial direction B_r as shown in **FIG. 9**.

[**0028**] Referring to top-view **FIG. 10**, the spacecraft has a clockwise angular velocity ω (A) which gives the conducting sphere a velocity v as shown by the vector (B). By the right-hand rule of physics, the angular velocity vector points in the negative z-direction. The angular velocity in the z-direction crossed with the radius r in the radial direction produces a velocity v in the clockwise θ-direction using cylindrical coordinates {r,θ,z}.

$$v_\theta = w_z \times r_r = -\omega r$$

[**0029**] Referring to **FIG. 11**, the negative radial dipole moment p_r crossed with the negative velocity v_θ of the sphere produces a positive magnetic moment μ_z in the z-direction.

$$\mu_z = p_r \times v_\theta = (-p_r)(-v_\theta) = pv$$

[**0030**] Referring to **FIG. 12**, the magnetic field B_z in the vertical z-direction is dotted with the magnetic moment μ_z in the z-direction to produce a force F_z in the vertical z-direction on each conducting sphere **(FIG. 13)**.

$$F_z = \nabla(\mu_z \cdot B_z) = \mu_z \nabla B_z$$

[**0031**] The magnetic field that is produced by the solenoid actually curves away and around. Thus there is a gradient of the field in the z-direction.

[**0032**] The force can also be expressed in tensor notation. The magnetic B field in the vertical direction is part of an electromagnetic 4×4 matrix Faraday tensor F

$$F^{\alpha}_{\beta} = \begin{array}{r|cccc|} & \beta = t & r & \theta & z \\ \alpha = t & 0 & 0 & 0 & 0 \\ \alpha = r & 0 & 0 & B_z & 0 \\ \alpha = \theta & 0 & -B_z & 0 & 0 \\ \alpha = z & 0 & 0 & 0 & 0 \end{array}$$

which shows that the magnetic field is located in slot $F^r{}_\theta$ of the Faraday tensor. In tensor notation the subscripts and superscripts have to match up on both sides of the equation. Matching subscripts and superscripts on the same side of the equation cancel. In this case, the electric dipole moment is in the radial direction p_r. The velocity can be represented as a time derivative of the θ-coordinate x^θ or

$$v^\theta = \frac{\partial x\theta}{\partial t}$$

[**0033**] Thus the force component in the z-direction becomes

$$F_z = p_r v^\theta F^r_{\theta,z} = (-p)(-v)\frac{\partial B_z}{\partial z} = pv\frac{\partial B_z}{\partial z}$$

where the angular and radial tensor components cancel and comma-z (, z) represents differentiation of the magnetic field in the z-direction.

[**0034**] The spacecraft design also has an inherent motion control system for moving in various directions. If the magnetic field of one solenoid arm is increased or decreased, the force on that sphere will be increased or decreased. Thus the spacecraft can turn in a particular direction.

DETAILED DESCRIPTION OF THE INVENTION

[**0049**] 1. Referring to the cut-away view **FIG. 14**, the construction of the spacecraft is a thin-wall insulating thermoplastic having a dielectric constant in the range of 20 kilovolts per millimeter (A). An insulated electrode (B) runs from the cabin power supply and high-voltage transformer

(C) to the tip of each tower (D). The four spheres (E) are silver plated to make them conducting. The tube solenoids (F) are driven by a direct current power supply (G).

[0050] 2. The present model uses 3D computer design software and stereolithography fabrication techniques to create the thin-wall, low-weight, hollow structure of the hull. The computer model is sliced into many thin horizontal slices. A laser, mounted on an x-y table, draws out the slice on a table immersed in a bath of liquid polymer. Due to its sensitivity to the light, the liquid polymerizes. The table is then lowered a few thousandths of an inch more and the process is repeated. Thus making hollow spherical and conical shapes is extremely easy to do. Parts can be designed and stored in *.STL stereolithography files for transmission by Internet e-mail to the service bureau machine shop which sends the finished parts back the next day by express mail.

I claim:

1. A spacecraft comprising:

a. a spherical cabin;

b. an electrostatic conical tower mounted on top of item (**1***a*), supporting a vertically-mounted negatively-charged insulated electrode at the tip of the tower;

c. an electrostatic conical tower mounted on the bottom of item (**1***a*), supporting a vertically-mounted positively-charged insulated electrode at the tip of the tower;

d. a vertical electric dipole created by items (**1***b*) and (**1***c*);

e. a high-voltage transformer to drive item (**1***d*), mounted in item (**1***a*);

f. four tubular arms, mounted at 90° around and extending at an angle from item (**1***a*);

g. four solenoids, each of which is mounted axially inside item (**1***f*);

h. a direct current power supply to drive item (**1***g*);

i. four silver-plated conducting spheres, each of which is mounted on the end of item (**1***f*);

2. an electrostatic lift system that:

a. produces a uniform spherical electric field by means of item (**1***d*) which envelopes item (**1***i*);

b. produces a perturbed electric field due to the presence of item (**1***i*);

c. produces an electric dipole moment in the direction of item (**1***b*) due to items (**2***a*) and (**2***b*);

d. produces a vertical magnetic moment due to the clockwise angular velocity of item (**1***a*) combined with item (**2***c*);

e. produces a vertical lift force on item (**1***i*) due to item (**2***d*) combined with the magnetic field gradient in the vertical direction produced by item (**1***g*); and

f. creates a motion control system by varying the current to item (**1***g*) in order to increase or decrease the effect of item (**2***e*) on a particular item (**1***i*).

POWERING ELECTRICAL DEVICES WITH ENERGY ABSTRACTED FROM THE ATMOSPHERE

Lloyd R. Crump, Silver Spring, Md.

Application March 12, 1954, Serial No. 415,986

1 Claim. (Cl. 321—2)

(Granted under Title 35, U. S. Code (1952), sec. 266)

The invention described herein may be manufactured and used by or for the Government for governmental purposes without payment to me of any royalty thereon.

This invention relates to the convenient and economical provision of power for the operation of electronic circuits and devices using transistors, and of other electrical devices having modest power requirements.

A great advantage of transistors, and a major reason for their enthusiastic reception since their introduction a few years ago, is the fact that they will operate satisfactorily with very low supply voltages and currents. One milliwatt or even less is sufficient to power a transistor in many applications. Various batteries have been developed to provide, in a minimum of space, the relatively minute amounts of power needed by transistors.

My invention provides methods and means that permit transistor circuits, and also other low-powered electrical devices, to be economically and conveniently operated without any batteries whatever, and indeed without any power supply whatever as power supplies are ordinarily conceived.

The invention centers around my discovery that it is practicable to construct operative transistor circuits that are able to abstract from the atmosphere sufficient electromagnetic energy to provide all necessary supply voltages and currents for their own operation. Circuits and devices powered according to my invention will operate indefinitely without any local power source whatever.

I have successfully constructed and demonstrated such circuits. For example, I have constructed a batteryless transistor radio receiver on which I have listened to either nearby or distant broadcast stations as desired, using either headphones or a loudspeaker; this receiver has been powered entirely by electromagnetic energy abstracted from the atmosphere.

From the successful operation of this receiver, and from other experimental work, it becomes clear that, by the methods and means of the invention, a great variety of practical and useful transistor circuits can be powered entirely by energy abstracted from the atmosphere.

Furthermore, as will become apparent below, my invention is applicable to the powering of other electrical devices requiring relatively small amounts of power.

An object of the present invention is to provide methods and means for powering transistor circuits entirely from radiofrequency energy abstracted from the atmosphere.

Another object is to provide methods and means for powering remote radio receivers, low-powered radio transmitters, and other low-powered electrical devices, with energy received by radio from a master station, so that no local power supplies are needed by the devices and so that the powering or non-powering of the remote device is under the control of the master station.

A further object is to provide methods and means for powering transistor circuits and other low-powered electrical devices with radiofrequency energy received from one or more remote radio transmitters.

Other objects, aspects, uses, and advantages of the invention will become apparent from the following description and from the drawing.

Figure 1 is a schematic diagram of a transistor radio receiver in which all necessary power is supplied by energy abstracted from the atmosphere in accordance with the invention.

Figure 2 is a schematic diagram showing a general application of the invention to provide direct-current power to a load.

Figure 3 is a schematic diagram of a system for obtaining a high energy D.-C. source at a high voltage level using energy abstracted from the atmosphere.

Referring to Figure 1, a receiving antenna **1** is connected to antenna coupling coils **2** and **3**, the other ends of which are connected to ground. A parallel resonant circuit consisting of coil **5** and capacitor **6** is coupled to coil **2**. A second parallel resonant circuit consisting of coil **7** and capacitor **10** is coupled to coil **3**. A third parallel resonant circuit consisting of coil **11** and capacitor **12** is also coupled to coil **3**.

Coil **5** and capacitor **6** are tuned to the frequency of a radio transmitter from which it is desired to receive information—for instance, an amplitude-modulated standard broadcast station. The signal received from this transmitter need not be strong. The signal is detected by diode **15** to obtain an audio-frequency information signal. This audio signal is coupled through a capacitor **16** and is amplified by a circuit that includes a transistor **17** having a base **20**, an emitter **21**, and a collector **22**. The amplified audio output of the transistor is coupled through an audio transformer **23** to an electroacoustical transducer, preferably a permanent-magnet dynamic loudspeaker **25** as shown.

The novelty of the invention lies largely in the method and means by which the necessary direct-current power is supplied to the emitter and collector circuits of transistor **17**. This method and means will now be described.

Coil **7** and capacitor **10**, and also coil **11** and capacitor **12**, are tuned to receive radio signals of relatively high strength. It does not matter whether these signals contain information. These power signals are rectified by diodes **26** and **27** to provide direct-current power that is filtered by capacitors **30** and **31**. The D.-C. power thus obtained is utilized to power the transistor **17**.

In the circuit shown, two tuned circuits (coil **7** and capacitor **10**, and coil **11** and capacitor **12**) are tuned to power signals and the D.-C. voltages obtained from each are connected in series. The tuned power circuits may be tuned to the same or different power signals. Under certain circumstances it may be desirable to use more than two tuned power circuits and to tune them to more than two power signals; in this way power can be obtained from several signals and combined. On the other hand, if a strong power signal is available, a single tuned power circuit may suffice to give the needed D.-C. power.

Even weak information signals can be received successfully. A plurality of transistor amplifier stages can be used if desired, or other circuits such as superheterodyne circuits can be used. It is merely necessary that a sufficiently strong power signal or signals be available to provide the small amount of D.-C. needed to power the transistors.

If the information signal happens to be strong, it can be used as the power signal; all of the tuned circuits (coil **5** and capacitor **6**, coil **7** and capacitor **10**, coil **11** and capacitor **12**) are tuned to the information signal.

Engineers who have observed my invention in operation have been surprised at the unexpectedly good results obtained, even with readily available power signals of quite moderate strength. For instance, sufficient power for satisfactory operation of a loudspeaker at low volumes is

readily obtained from a 5-kilowatt standard broadcast station 5 miles away, using only an indoor antenna to pick up the power signal as well as information signals. In typical operation under these conditions a D.-C. voltage of about 2.5 to 3 volts is obtained between the emitter and the collector, at a current of about 250 microamperes; D.-C. power input to the transistor is thus of the order of 0.5 to 1 milliwatt. So far as I am aware, no one has ever before discovered and demonstrated the practicability of this method of powering a radio receiver.

Because existing broadcast stations within a radius of a number of miles provide adequate power signals, the invention is readily practicable with existing power signals in almost any location in or near any city in the United States.

Although I have described a transistor radio receiver powered by my invention, it will be readily apparent that the invention is applicable to the powering of any transistor circuit using one or a number of transistors, and to the powering of other devices requiring relatively small amounts of power. For instance, sensitive electromechanical, electrochemical, or electrothermal devices can be operated by the method of the invention.

Referring to Figure 2, which shows a more general embodiment of my invention, an antenna **35** picks up radiofrequency energy from the atmosphere. This energy flows through coil **36**, which is coupled to a tuned circuit consisting of coil **37** and capacitor **40**. The radiofrequency voltage across capacitor **40** is rectified by diode **41** and filtered by a low-pass filter **46** consisting of capacitors **42** and **44** and choke coil **43**. The resulting D.-C. voltage is applied to a load **45**.

In the practice of my invention, larger amounts of power can be obtained for short periods of time by storing received energy in a suitable energy storage device. Stored energy may then be withdrawn at intervals at a more rapid rate than that at which it was received and put into the storage device. In this way the invention can be used to provide short pulses of relatively very high electrical energy. This result can be readily obtained by charging a relatively large capacitor with direct current and then discharging the capacitor rapidly into a load when desired. This rapid discharge can be initiated automatically when the voltage across the capacitor reaches a certain level, or it can be initiated when a transistor radio receiver receives a certain information signal.

Higher voltages can be obtained with the invention by means of well known devices for raising D.-C. voltages as shown in Figure 3. The D.-C. voltage output from the capacitor **44** can be used to power a low frequency transistor oscillator **52** whose A.-C. output is raised to a higher voltage level by the transformer **55**. This relatively high A.-C. voltage can then be rectified by a diode **61** and fed to a capacitor **64** to provide a high energy D.-C. source at a relatively high voltage level at the terminals **69** and **70**. If desired, energy can now be withdrawn from the capacitor **64** at intervals in short pulses of high energy at a high voltage level. Pulsed radio transmission is one of the possible uses for this form of the invention. Other uses would be to provide a single relatively powerful pulse needed to actuate an electrothermal or electromechanical device.

As has been indicated above, in many locations and particularly anywhere in or near most American cities, power signals normally present in the atmosphere are readily available for the easy and convenient practice of the invention. However, the invention also has important applications in systems in which the necessary power signal is generated and transmitted specifically for the operation of the particular system. Such systems can, for example, comprise a master station transmitting all the power that is needed for hundreds or thousands of fixed or mobile transistor receivers or other remote devices over a range of many miles. This eliminates the need for hundreds or thousands, as the case may be, of local power supplies. At the same time, such a system has the advantage that all of the remote devices can be simultaneously activated or deactivated at the will of the master station, simply by starting or stopping the transmission of the power signal. In such systems it will often be advantageous to use power signals of frequencies sufficiently high to permit the use of resonant receiving antennas of small physical dimensions for signal pickup at the remote devices. In addition to the power signal, the master station may transmit an information signal on the same or a different carrier.

Certain types of devices powered entirely by received radio waves are of course well known. The well-known "crystal set" of the early days of radio, which used a diode rectifier to demodulate an amplitude-modulated radiofrequency signal, is an outstanding example of such a device. My invention is readily distinguishable from such prior devices, however. In typical prior devices a modulated radiofrequency signal is applied to a diode to obtain unidirectional half-wave pulses whose amplitudes vary with modulation. These pulses are integrated by means of a capacitor to obtain a unidirectional signal the amplitude of which follows the audiofrequency modulation envelope. If the radiofrequency signal is received with sufficient strength the audio signal may have sufficient power to operate headphones or similar utilization device without power amplification; but the signal is utilized for its information content, rather than to supply non-information-containing power.

My invention, on the other hand, entails the utilization of received radiofrequency energy to supply power to at least one pair of circuit points (across capacitor **31** in Fig. 1, for example), such circuit points requiring power solely for its power content and not for any information or modulation it may contain. In other words, my invention entails the utilization of radiofrequency energy to supply power that would otherwise have to be supplied by batteries, generator, or other local power source.

It will be apparent that the embodiments shown are only exemplary and that various modifications can be made in construction and arrangement within the scope of the invention as defined in the appended claim.

I claim:

An electrical device for obtaining a high energy D.-C. source at a high voltage level using energy abstracted from the atmosphere, said device comprising in combination: resonant means for receiving radio waves, first rectifier means for converting said radio waves into first direct current energy, first capacitor means for storing said first direct current energy, an oscillator powered by said direct current energy, said oscillator producing an A.-C. output, transformer means for raising said A.-C. output to an increased voltage level, second rectifier means for converting the A.-C. output of increased voltage level from said transformer into second direct current energy, and second capacitor means for storing said second direct current energy.

(57) **ABSTRACT**

This device is a brushless high-voltage electrical generator, requiring suitable means of input rotary torque, for purposes of producing a very-high-energy external electrodynamic field or continuous quasi-coherent DC corona or arc discharge of uniform current density which completely encloses the machine's conductive housing. This housing is divided into distinct electrical sections and contains a flat conductive rotor which electrically links separate negative and positive housing sections and upon which a plurality of toroidal generating coils are rotatably mounted. Circular arrays of stationary permanent magnets are affixed within the housing which induce a constant DC voltage within said coils upon their rotation. The primary voltage so-generated is electrostatically impressed across the rotor such that great quantities of electronic charge may be transported between the opposite polarity sections of the housing, in such a manner that a much higher secondary voltage is caused to appear across interposed neutral sections thereof, and the resulting external breakdown current once initiated is independent of the generating coils' ampacity. Ancillary mechanical, electrical, an/or electronic features may be attached upon or within the housing to aid in harnessing and controlling the useful effects associated with the external dynamic electric field produced by the device.

ELECTRODYNAMIC FIELD GENERATOR

FIELD OF THE INVENTION

The present invention is related in general to rotary direct current (DC) electrical generators which incorporate permanent magnet fields, and in particular to similar electromechanical generating devices whose principal purpose is to produce a useful continuous high-voltage DC corona discharge. This invention also pertains to the field of aerospace vehicles which are capable of propulsion through the utilization of an ultra-high-voltage corona or arc discharge of a special type and form.

DESCRIPTION OF RELATED ART

In order to provide background information so that the present invention may be completely understood and appreciated in its proper context, reference is made hereinbelow to a number of related art patents. These cited references contain certain similarities to the present invention, primarily related to the objective of producing electrically-developed thrust. However, key differences and limitations with regard to achieving this objective are in evidence.

The related art disclosed in U.S. Pat. No. 2,949,550 proposes three attendant objects which are quite similar to certain of the objects of the present invention: (i) to provide an apparatus for the direct conversion of electrical potential to usable kinetic energy; (ii) to provide such an apparatus having a hollow body or housing which contains a source of high electrical potential; and (iii) to provide a self-propelling vehicular apparatus which includes a pair of electrically conductive body portions joined by an insulative portion, whereby said conductive portions constitute electrodes. A further similarity is that the vehicular embodiment proposed preferably be of a circular disc shape somewhat thicker in its center than at its edges. The device set forth in this Patent just cited is noticeably different from the present invention, however, in that a positive voltage is applied to the housing periphery and a negative voltage is applied at the central axis. The proposed arrangement is furthermore limited to operation within a gaseous dielectric medium, upon which it is reliant for the production of the claimed motive force, and is to be operated at a potential gradient less than that which would produce a visible corona. This device moreover makes no provisions for the production and/or extraction of vast quantities of useful thermal kinetic energy, as the present invention does.

The related art disclosed in U.S. Pat. No. 3,071,705 is based on three empirical principles of electrostatics which also figure prominently in explaining the actual shape of the discharge current field that will be produced by the present invention: (i) electrostatic lines of force tend to concentrate on the surface of a charged conductor in those places with the smallest radius of curvature; (ii) they are normal to the surface from which they emanate; and (iii) they do not cross but will bend under the influence of another charged body. The device set forth in this Patent just cited is in fact quite similar to that of the Patent cited immediately before, in that relatively massive positive atmospheric ions and entrained neutral air molecules are repelled from the positive electrode toward the negative electrode along a linear axis—thereby inducing an air flow or "electric wind" which represents the fundamental source of thrust. It is therefore once again limited to operation in a gaseous dielectric medium, and does not make use of a flow of negative and greatly less massive electron current in the course of thrust production—which may achieve comparatively enormous acceleration and even relativistic velocity and specific impulse at a similar given level of applied potential gradient—as the present invention does.

The related art disclosed in U.S. Pat. No. 3,177,654 actually addresses the issue of producing electrically-developed thrust which is not limited to atmospheric operation, and the stated primary object thereof is to provide a propulsion system for enabling controlled flight in the atmosphere which may continue extensively into space without changing the system's basic operation. One embodiment thereof also proposes a circular disc-shaped vessel wherein high-voltage electrode elements ionize atmospheric gases by corona discharge, and a pulsed electromagnet arrangement causes the ejection of the resultant plasma from the propulsion chamber—producing thrust by reaction. This device furthermore addresses the issue of producing local thrust differential(s) on the body or housing thereof, for purposes of flight maneuvering and/or directional control, by providing for a plurality of such pulsed discharge propulsion units arranged in concentric rings (within the discoid body) and having individual divergent nozzles. As such, however, the device set forth in this Patent just cited actually constitutes an ionized jet propulsion method, requiring the use of either a gaseous medium like air or the onboard storage and release of relatively massive ionizable reaction material for any operational capability in space. Moreover, the pulsed mode of operation used, which limits the ionizing potential gradient to a value of less than breakdown field intensity, significantly restricts the level of power produced as thrust as compared to the continuous DC discharge field current produced by the present invention—at voltages which may be greatly in excess of breakdown intensity. Finally, this said device relies upon an unspecified source of generated electrical power in operation which must be assumed would have to be nuclear if conventional in nature, for said device to avoid otherwise having to carry a massive and range-limiting onboard store of fuel, and not upon convenient and protracted-use permanent magnets of high energy density as the prime energy source (as the present invention does).

U.S. Pat. No. 3,464,207 discloses a quasi-corona aerodynamic vehicle which bears only a limited relationship to the present invention, but which is referenced nonetheless as being further indicative of the predominant trend in conceptualization in relation to devices intended for producing electrically-developed thrust. This device also relies upon pulsed corona discharge operation between spaced electrodes at less than breakdown field intensity, thereby greatly constraining the propulsive power obtained. It is furthermore effective only in a gaseous dielectric medium and is based upon an electric wind pressure gradient arising of an admitted incompletely-understood mechanism. This same device evidences a great deal of theoretical complexity and construction material specificity, which might seem to indicate a narrow range of feasibility. Such attributes are not uncommon in the field of electrical aerospace propulsion, and are, to a degree, shared even by the present invention. Nevertheless, it is interesting to note that sizeable thrust in the form of an aerodynamic pressure gradient or lift of up to 30 lbs./ft^2 of external electrode area or more is asserted to be obtainable from said same device by utilizing asymmetrical electrodes or electrode arrays, rather than using electrodes or electrode arrays of approximately equal area (as the present invention does)—which therefore present a uniform cross section of discharge current conduction.

PCT Application WO 85/03053 discloses a flying apparatus whose primary similarity to the present invention is that it incorporates a hollow annular flywheel which provides gyroscopic stability and encircles a relatively stationary central cabin and/or payload area. The device set forth therein also provides free-rolling means to center and stabilize the flywheel or rotor within a discoid housing, and addresses the issue that horizontal flight maneuvering and/or directional control may be accomplished by altering the local angular acceleration of the rotor—as does the present invention. This said other device, however, relies upon the questionable concept that the very large angular momentum of the rotating flywheel is somehow able to compensate the potential energy caused by gravitation and that the overall weight of the apparatus may thereby be annulled. Vertical lift must then be provided for said device in operation by atmospheric thermal updraft means, and no electrical discharge means are utilized to produce a force of lift or thrust.

The device set forth in UK Patent GB 2 312 709 A is a flying craft which is essentially disc- or saucer-shaped and which has a central axial post electrode and a spaced enclosing ring electrode whereby an electrical arc may be struck between the two, to either ignite fuel introduced via nozzles or greatly heat an exhausted air flow produced by fan means. Thus, this device actually provides hybrid jet or turbo-fan means for producing propulsive thrust, and utilizes direct electrical discharge not as the primary source of thrust but to enhance thrust produced by other means. To this end, said device must therefore operate solely in a gaseous atmosphere and/or carry onboard a range-limiting store of combustible fuel. This same device does, however, utilize powerful magnetic fields to impart a rotational and de-randomizing aspect to the arc discharge, thereby promoting a more uniform distribution of the arc discharge field's energy, as does the present invention.

In summary, a number of similar or significant electrical, magnetic, and mechanical features of the several related art devices have been examined but, whatever the precise merits and advantages thereof, none of said devices achieve the correct combination of such features required to fulfill the purposes of the present invention. In this respect it may be stated that none of these related art devices attain the distinction of being able to operate extensively in the vacuum of space without the onboard storage of relatively massive reaction material for the production of thrust. Furthermore it would appear that none of these same devices utilize a charged conductive housing comprising suitably disposed electrodes and/or electrode arrays to create and control an asymmetrical electromotive field of force on itself without expelling a reaction mass, whether in a gaseous dielectric medium or the vacuum of space, to achieve a propulsive object as the present invention does. Finally, it is observed that none of the aforementioned related art devices can develop this type of useful thrust-producing electrodynamic field in a manner which allows more than one objective function to be fulfilled thereby, such as the production of useable thermal kinetic energy and/or the development of potential signal communications capability.

SUMMARY OF THE INVENTION

The present invention is a brushless permanent magnet electrical generator which produces a useful ultra-high-energy external electrodynamic field, or continuous quasi-coherent DC corona or arc discharge of uniform current density, that completely surrounds and encloses the machine's symmetrically disc-shaped conductive housing and tends in consequence toward a balanced bihemitoroidal shape.

The invention incorporates a uniform arrangement of stationary electromagnetic armatures which may be employed as a group to impart a holistic and de-randomizing rotational force to the external discharge current that acts to inhibit the formation of concentrated arc streamer or channel phenomena, and thus to assist in rendering the electrodynamic field quasi-coherent in nature. The arrangement of electromagnetic armatures in said generator acting as a group simultaneously also contribute a portion of the machine's required input rotary torque upon the current-carrying rotor assembly thereof.

This invention provides a permanent magnet high-voltage generator wherein the primary DC voltage induced within its rotating coils is electrostatically impressed across the conductive rotor assembly thereof, in a brushless manner utilizing vacuum tube cutoff bias techniques, such that a secondary DC corona or arc discharge current is thereby initiated about the housing thereof which is orders of magnitude larger than the operating current through the said coils.

The said high-voltage primary generator of the invention then has a housing or hull which is divided into separate negative (emitter), neutral, and positive (collector) electrical sections, such that the continuous external flow of such discharge current is best facilitated and conducted internally by the proximal rotor, and wherein suitable means to circulate one or more form(s) of liquid coolant through any one or more of said housing sections may be employed for purposes of extracting an extremely high level of recoverable thermal energy (arising from such discharge current)—which is intended principally for use in the large-scale production of electrical power and/or distilled or desalinated water.

This invention as an electrodynamic field generator also provides an appreciable and practical level of electrically-developed thrust, from the relativistic impulse of an induced ultra-high-voltage external DC arc discharge current incident upon its positive (collector) housing sections, which may be rendered variably non-isometric in nature and therefore directionally propulsive by means of selectively controlling: (i) the resistance of the brushless electrical linkages between the positive housing sections and the proximal current-carrying rotor; and/or (ii) the magnetic flux output of the various stationary electromagnetic armatures.

The invention as an ultra-high-energy field generator furthermore presents a unique yet practicable method of producing a variable electromagnetic and/or gravimetric signal, by means of which useful information may be both transmitted to and received by a separate similar device, in further harnessing the effects associated with the device's external electromotive field. The relationship of said field effects to quantum potential vacuum fluctuation theory just now being studied, which may allow the devising of such a signal having an unconventional nature, is referred to again below.

In any event, the electrodynamic field generator described may be feasibly manufactured and marketed in various sizes according to need or desire in pursuit of its remarkable objects; may be operated either in a gaseous dielectric medium or in the vacuum of space; and may incorporate ancillary mechanical, electrical, and/or electronic features upon or within its housing to accomplish all the objects set forth hereinabove.

Briefly, in accordance with the preferred embodiment of the invention, first provided is a flat annular segmented rotor of very high conductive ampacity which is rendered capacitive in nature by the attachment of suitably paired electrode rings. Alternating in placement amidst such capacitive ring pairs are also attached on the rotor a series of toroidal generating coils of very large mean radius relative to the cross-sectional radius thereof. The resultant composite rotor assembly is then rotatably mounted within a sectional conductive housing. The potential energy inherent in the fields of ring-shaped stationary permanent magnets, which are affixed in concentric circular arrays within the housing, is utilized to electrically polarize the rotor across its radial annular width by means of the "primary" DC voltage created upon relative rotational motion between such coils and magnets. The thereby polarized rotor is electrically linked on one hand (about its positive inner circumference) to two axially-central collector housing sections, by electrostatic induction via a system of plane-parallel electrode elements, and on the other hand (about its negative outer circumference) to two radially-peripheral emitter housing sections across an evacuated space charge chamber. The rotor's subsequent transportation and storage of electronic charge between the proximal opposite-polarity sections of the housing causes a much higher "secondary" voltage to appear across interposed neutral sections thereof and results in a continuous ultra-high-energy DC discharge current flow about the housing externally and across the rotor internally.

BRIEF DESCRIPTION OF THE DRAWINGS

The benefits and advantages attendant to the invention and its objects as discussed hereinabove are best illuminated through the following drawings and description.

FIG. **1** shows a side sectional view of the invention's peripheral and principal working structure, comprising a rotor assembly as well as frame-mounted elements.

FIG. **2** shows a top sectional view of a 30° radial sector of that same working structure.

FIG. **3** shows a side view of the invention's symmetrical housing or hull configuration.

FIG. **4** shows a top view or bottom view of that same housing/hull configuration.

FIG. **5** depicts a small radial sector of the basic rotor assembly construction, in top view, details of the rotor segments, inter-segment insulators, and field emitters.

FIG. **6***a* and **6***b* show side and top views, respectively, of one of the invention's conductive rotor field emitters.

FIG. **7** shows a simplified schematic representation of the invention's two "primary induction ring" electrode arrays, in relation to the rotor electrical circuit.

FIG. **8** shows a schematic of one symmetrical half of the primary power system circuit of the invention, in a "single-stage" rotor construction embodiment.

FIG. **9** shows a schematic of one symmetrical half of that same primary power system circuit, in a "three-stage" rotor construction embodiment.

FIG. **10** shows a schematic of the field voltage control system circuit of the invention.

FIG. **11** shows a simplified diagram of the electrodynamic field "envelope" produced by the invention, around a side view of the invention's housing/hull.

FIG. **12** shows the diagram of FIG. **11**, with the addition of lines indicating the electric and magnetic field vectors comprising that same electrodynamic field envelope.

FIG. **13** shows a top or bottom view corresponding to the side view of FIG. **12**.

FIG. **14** shows a top or bottom view of a radial sector of the invention's neutral hull section, showing the housing cooling and/or heat transfer system arrangements.

FIG. **15** shows a detail of an embodiment of the preferred central rotor segment attachment means and rotor drive assembly.

FIG. **16** shows a schematic of the stationary armature power circuit of the invention.

DESCRIPTION OF THE PREFERRED EMBODIMENT

Method of Operation

The invention disclosed herein is an Electrodynamic Field ("EDF") Generator. The primary challenge involved in fulfilling the objects of the present invention is how to generate and maintain a multi-megavolt potential difference across the exterior sectional housing which is not immediately neutralized due to uncontrolled direct arc discharge. The first part of the problem in this respect is that it is not possible to produce this kind of voltage directly within a traditional generating coil arrangement, so the voltage applied to the charged housing sections must be achieved by special electrostatic means. Secondly, the discharge current must be produced and conducted internally in such a manner that: (i) only a tiny percentage thereof is actually conducted by the generating coils (within their very limited ampacity compared to that of the rotor); and (ii) the negative and positive housing sections are each charged faster than they are discharged until an enormous equilibrium field potential difference is established which is a sum of roughly equal negative and positive housing section voltages.

Having thus stated the principal parts of the overall problem, it is perhaps best to examine and explain the means to its solution in the reverse order. Therefore, it is deemed of fundamental import to realize that the EDF Generator's housing configuration as proposed will demonstrate a significant static capacitance, despite its unusual geometry, given the fact that the negative and positive sections of its housing are to have essentially equal surface areas. This simple precept ensures two very important consequences: (i) that the voltage across the housing will attain a value representing equal negative and positive potentials, in reliance upon the absence of a fixed ground reference, given induced surface charge densities which are sufficient to cause a continuous 'leakage' current between the opposite-polarity sections thereof; and (ii) that a leakage current between the opposite-polarity housing sections will tend to assume a relatively uniform cross section and current density in response to a calculable level of non-uniform surface charge density between non-parallel but equal-area 'plates'. Thus, it is possible to determine using traditional formulas just how much electron charge must be stripped from the positive housing sections, and stored in ballast capacitors, in order to establish a positive surface charge density which corresponds to the desired housing or hull potential difference.

Next, the Generator must, and will, be able to charge these positive housing sections (by stripping them of native electrons) far faster than the positive surface charge so-created is neutralized by corona or arc discharge from the negative housing sections. Because these discharge current electrons will ultimately attain a transit time approaching zero, this in turn means that it must be "easier" per volt to strip negative charge from the positive sections—using a field induction system which is comprised of "primary electrode arrays"—than it is to deliver this charge to the negative sections across a vacuum chamber using relatively massive rotor-mounted field emitters.

It can be shown that the potential difference across said primary arrays will tend to be equal and opposite in operation as proposed to that across such vacuum chamber, in part due to the Faraday shielding principle, and the negative 'plate' voltage of the capacitive housing will naturally tend toward numeric equality with that of the positive sections by electrostatic induction. Therefore, the stationary electron-emitting primary cathodes which link the positive sections of the housing to the rotor are to have a much lower surface work function (and higher emissivity) than the rotating electron-emitting elements which link the rotor with the negative housing sections. This criterion is achieved by thorium-impregnating these cathodes (to stimulate their emissivity) and by not so-impregnating the rotor field emitters.

The relationship just described establishes what electrical engineers refer to as an 'instantaneous charge differential' with respect to these two sets of components as operated at equal but opposite charging voltages or potential differences, and the ratio of their respective electron emissivities will thus define the maximum ratio by which the said secondary field voltage (across the exterior housing) can be expected to exceed that in evidence across the stationary internal primary electrode arrays. This ratio will hereinafter be referred to as the "primary voltage expansion ratio", and the instantaneous charge differential concept as well as its relationship to the said voltage expansion ratio will be explained in further detail in a pertinent section to follow. It is important to note at this point, however, that for this voltage expansion to be realized it must and will be supported by ballast capacitors having suitable total capacitance as outlined hereinabove, which provide a corresponding force of electrostatic induction.

Finally, a method of impressing as large a primary DC voltage across the rotor as may practicably be developed in the device's principal generating system must and will be employed, without such "Primary Power System" circuit conducting more than a minute percentage of the discharge current thereby initiated. To do so, and in a manner that requires no brushes, vacuum tube cutoff bias technique is utilized in the present invention: whereby such primary voltage is electrostatically induced upon the rotor between two sets of capacitive electrode ring pairs (in vacuo), yet the current flow across these rotor-mounted induction electrode arrays—and through the principal generating circuit itself—is absolutely minimized by the application of a control grid voltage which is substantially negative with respect to the corresponding cathodes.

At a certain relative potential, the electrostatic force exerted by such control grid(s) on rotor circuit cathode-emitted electrons is sufficient to all but completely cut off the flow of DC current across these rotor induction arrays; yet the primary DC voltage is transmitted to the large conductive rotor segments such that a comparatively huge charging current between the opposite-polarity housing sections is initiated and maintained (across the rotor)—which subsequently expresses the expanded secondary voltage as a discharge current about the housing. Thus, an analogy could be made in describing the EDF Generator as a DC equivalent for boosting voltage by electrostatic induction means to the AC transformer (for boosting AC voltage by electromagnetic induction means).

General Form of the Invention

Accordingly, referring to FIGS. **1** through **4**, the present invention constitutes a novel form of brushless permanent magnet electrical generator for producing a useful ultra-high-energy external electrodynamic field, or continuous quasi-coherent DC corona or arc discharge of essentially uniform current density, and as such the Generator fundamentally comprises and incorporates:

[A] a flat conductive rotor **(6)** principally formed of a large number of evenly-spaced individual metallic conductors or segments **(14)** and an equal number of conductive electron-emitting elements or field emitters **(17)**, radially arranged in an annular flywheel configuration rather like the rotatable deck of a carousel, which are all connected in parallel electrically by the attachment of a thin metallic electrode ring **(68)** about the positive inner circumference of each of the two major flat faces of the annular flywheel thus formed and by the attachment of another such ring **(22)** about the negative outer circumference of each such flat rotor face;

[B] a principal electrical generating system mounted on said rotor and used to create a very high primary DC voltage within a plurality of rotating toroidal field coils **(35)(40)(56)** by electromagnetic induction with an equal number of circular arrays of ring-shaped stationary permanent magnets **(34)(39)(55)** (which are positioned adjacent and concentric thereto), such that an internal primary discharge current may thereby be initiated between the rotor **(6)** and a housing electron "Emitter Ring" **(47)**—across an evacuated space charge chamber **(11)**—which is orders of magnitude larger than the operating current through said field coils;

[C] a conductive exterior housing **(1)** divided into a plurality of distinct electrical sections—negative **(3)**, neutral **(4)**, and positive **(5)**—which may be charged from the internal rotor by electrostatic induction and/or by such primary discharge current (as the case may be) and within an evacuated induction compartment **(12)** of which said rotor **(6)** as an assembly, including the said generating coils attached thereto, is rotatably mounted;

[D] a plurality of individual systems of stationary plane-parallel electrode elements **(64)**-**(67)** which electrically link the polarized rotor **(6)** by electrostatic induction about its positive inner circumference (within said evacuated compartment **(12)**) to two axially-central electron collector housing sections **(5)**, and a plurality of similar individual systems of rotor-mounted plane-parallel electrode rings and/or radial electrode elements which may be utilized to connect a principal portion of the individual DC voltage outputs of said rotating field coils in opposed series-parallel across such composite rotor assembly;

[E] this composite rotor assembly **(6)** as a means for the transportation and capacitive storage of electronic charge between opposite-polarity sections of the housing **(5)** and **(3)** (which are proximal to the inner and outer rotor circumferences respectively), such that a vastly higher secondary voltage is caused to appear across interposed neutral housing sections **(4)**, resulting in a continuous ultra-high-energy DC discharge current about the housing externally which is also conducted internally across the rotor segments **(14)** that extend across the neutral housing portion and between the positive sections;

[F] a large number of stationary electromagnetic armatures **(37)** in a uniform circular arrangement located within the neutral electrical region **(4)** of the housing which are to be operated principally on variable DC voltage, but which may also accept limited pulsed unidirectional or alternating voltage input, and which are employed as a group to impart an orderly rotational magnetic vector moment to the external discharge current that acts to inhibit the formation of concentrated arc streamer or channel phenomena and thus to assist in rendering such current quasi-coherent in nature; and

[G] the said principal electrical generating or Primary Power System as operated and used in such a manner that a minor pulsed unidirectional or alternating voltage is superimposed upon the high-energy DC rotor current, and the external discharge current therefore acquires a discrete AC power factor, for purposes of modulating the electrodynamic characteristics of the external field during normal operation and/or for purposes of exploring the invention's potential signal communications capability in relation to intriguing new theories in high-energy quantum physics and relativity.

In a "single-stage" rotor electrical circuit embodiment of the Generator, as intended for use in an electrical and/or thermal energy output application, any such minor AC voltage present in said rotor circuit receives only a modest and single level of amplification—in a manner generally associated with a single multi-electrode vacuum tube. In a "three-stage" rotor electrical circuit embodiment of the Generator, as intended for use in a propulsive and/or communications application, any such minor AC voltage may receive a substantial and multiple level of amplification—in a manner generally associated with a multiple number of sequentially-coupled multi-electrode vacuum tubes.

FIG. **1** shows a side sectional view of the general form of the invention, as if cut through the central axis of the circular structure. Only one side of the tapered peripheral portion of the structure is shown, the overall Generator being symmetrical about the axis along which the section shown is cut. FIG. **2** shows a top sectional view of the invention, as if cut through just above the rotor assembly at the "equator", with only about a 30° radial sector of the circular structure shown (the remaining 330° being identical around the Generator). In each case, identical reference numbers are used to indicate identical elements. FIGS. **3** and **4** are side and top or bottom views of the Generator (respectively), showing the outward appearance of the invention and the external field it produces. The following discussion of the general form of the invention will be in reference to FIGS. **1** to **4**, unless otherwise noted.

The entire apparatus of the invention is contained within a circular conductive exterior hull or housing **(1)**, which is tapered from its vertical centerline ("axis") to its rim (or "equator"). The overall housing is radially symmetrical around the axis, and bilaterally symmetrical about the equator. This housing's two central one-base spheric-zone-shaped sections **(5)** will be positively charged, its two intermediary conical ring-shaped sections **(4)** will be electrically neutral, and the convergent outermost or peripheral conical ring-shaped sections **(3)** will be negatively charged. Preferably, the surface areas of the outer **(3)** and inner **(5)** housing sections are equal, and specific details of the housing or hull design are given in a section to follow.

Each of the housing's two symmetrical positive sections **(5)**, or hull positive "zones", should be divided into equal-area radial sectors **(42)** which are equal in number to the number of like sections into which the device's superstructure is divided. Thus, in the preferred embodiment of the Generator these two positive zones **(5)** will each be divided into 36 such sectors, and isolated top and bottom, yielding a total of 72 individually controllable discharge collector areas. The positive zone sectors **(42)** jointly comprise what may hereinafter be referred to as the device's "Field Hub", and should be composed of a conductive refractory metal or high-temperature structural alloy such as #310 stainless steel. These positive sectors are insulated from sector-to-sector by insulating "partitions" **(43)** of a suitable ceramic material (such as Cordierite), and must be supported by an insulating understructure (not shown).

At least one hull "neutral ring" surface layer **(46)** is also to be affixed on a housing frame and composed of one or more insulating ceramic material/s (such as Cordierite, Zirconia, and/or Kézite, as necessary). Said neutral hull layer/s may be applied in the form of plates and/or tiles to nonmetallic "deck" sheeting (not shown separately) supported by superstructure beams **(153)**. This decking and its supporting beams are both preferably composed of a carbon composite material, and will thus be fairly conductive. Therefore, both must be isolated from the positive Field Hub by a dielectric buffer material **(45)** and from the hull's Emitter Ring **(47)**, comprised of two negative housing sections **(3)**, by an auxiliary dielectric buffer **(50)**. The Generator's neutral housing section superstructure is shown in detail in FIG. **14**, as is a piping system of coolant tubes or "thermal conduits" **(74)**-**(79)** for maintaining the hull neutral sections **(4)** and superstructure—as well as the enclosed Primary Power System—at an acceptable operating temperature. Such an intercooler system would utilize a cryogenic coolant such as liquid air or nitrogen when the EDF Generator is operated in the atmosphere for purposes of thermal energy output, and will be explained in greater detail in a section to follow.

The negative hull plates which form each section **(3)** of the Generator's peripheral Emitter Ring **(47)**, to which the rotor **(6)** distributes the discharge current forming the exterior field envelope, should be composed of high-purity aluminum which is copper-clad and then nickel-plated to prevent erosion at high field voltage and current levels. The abutting edges of all of the adjacent such plates must be welded one to another, and affixed to any necessary neutral hull section hardware, such that a hard vacuum may be drawn within the peripheral chamber **(11)** thereby formed. The induction compartment **(12)** enclosed between the two neutral hull sections **(4)** is contiguous with the peripheral or space charge chamber **(11)**, and thus is equally evacuated.

A pressurizable central chamber **(2)** within the housing **(1)**, located between the two hull positive zones **(5)** thereof, constitutes the location of the Generator's control cabin and of its payload area when used as an aerospace vessel. The interior **(11)**-**(12)** of the negative **(3)** and neutral **(4)** housing sections (respectively) is separately sealed, and must be as highly evacuated as possible to promote the efficiency of the various rotating and stationary electrode arrays and to prevent their destructive failure. The main vacuum seals **(155)** and the rotor's vacuum chamber charge buffers **(156)** are shown in FIG. **1**.

Inside the evacuated induction compartment **(12)** of the housing **(1)**, and surrounding the central chamber **(2)**, is located the composite rotor assembly **(6)** in the form of a flat annular flywheel. In the preferred embodiment, 180 individual conductors or segments **(14)** of very high collective ampacity are employed in the rotor, as will be seen in the discussion of FIG. **5** below, as are a like number of inter-segment insulators or segment "separators" **(16)**. The preferred material for the rotor segments is high-purity copper which is certified oxygen-free, to resist the production of free oxygen radicals at high operating temperatures which would degrade the performance of the various electrode arrays and cause an undesirable increase in vacuum chamber **(11)** temperature.

The inner ends of the rotor segments (**14**) and segment separators (**16**) are mechanically connected via a retaining and lockdown section thereof to one or more ring gear(s) (**8**), which run/s entirely around the central aperture of the rotor assembly. Suitable insulating attachment hardware (**7**), as described in detail in the following section (and shown in FIG. **15**), will be used to effect a rigid mechanical union of the segments and separators to the said ring gear(s) and associated drive means such that the gear(s) and all conductive components of such drive means are electrically isolated from the energized segments. The ring gear(s) (**8**) may be engaged by one or more pinion or drive gear/s (**162**) powered by a motor (**9**) or plurality thereof, which may be of various types (such as electrical or hydraulic), causing the rotor to rotate around the central chamber (**2**). The rotor is supported near its outer edge by two ballraces (**25**) mounted to the housing superstructure and to the rotor, and having bearing balls (**26**), allowing it to spin freely.

As can be seen in either FIG. **1** or **7**, the rotor segments (**14**) are electrically connected together at each end by continuous inner (**68**) and outer (**22**) electrode rings, and also at intermediate points by induction cathode rings (**28**) and induction anode rings (**61**). The inner electrode rings (**68**) constitute the primary induction ring array anode elements, as will be described below. The outer electrode rings (**22**) are each covered by a dielectric layer (**23**) which is in turn covered by an anode ring (**24**), and each combination of rings (**22**) and (**24**) separated by dielectric layer (**23**) forms a housing charge ballast capacitor whose function will be explained in detail below. Induction anode rings (**29**) and cathode rings (**59**) are used to electrostatically induce corresponding negative and positive voltages on rotor-mounted rings (**28**) and (**61**), respectively, thereby electrically energizing the rotor segments as will also be described in further detail below.

FIG. **5** shows details of the basic rotor construction. Wedge-shaped ceramic pieces or segment separators (**16**) equal in number to the conductive rotor segments (**14**) are to be positioned uniformly between the individual segments, as are the rotor's peripheral field emitters (**17**). To form the base rotor construction, the segments, separators, and field emitters must be equal in number, preferably using 180 of each. The said segment separators are actually more structural than insulative in purpose, and not only stiffen the entire rotor to prevent its distortion at elevated temperature and rotational speed but also provide a nonconductive base for mounting all other rotor assembly components. Each of the ceramic separators (**16**) is bonded to its adjacent segments (**14**) by refractory adhesive layers (**15**).

Two important criteria for selecting a ceramic segment separator material are that the compound chosen be readily machinable like steel and provide very high physical strength yet require no firing. These parameters limit the choice made almost to a solitary substance: magnesium silicate ($MgSiO_3$). When suitably formed, this material can be milled, drilled, and tapped like steel (using low-speed tungsten carbide tools) and approaches the physical strength of dry-pressed porcelain. It is ready for use directly after shaping and requires no kiln hardening.

This latter characteristic is very important as it is extremely difficult to produce fired ceramic pieces with the exacting dimensional control necessary in this case, and it eliminates the tendency of thicker fired pieces to develop micro-cracks which may potentially cause destructive failure of the component under high centrifugal loading. Surfacing can be done with abrasive paper or grinding wheels, and it is very important that this material be machined or worked perfectly dry as it is fairly porous and any lubricant used tends to significantly alter its dielectric properties. Magnesium silicate of this type is available from CeramTec NA as CeramTec designation AlSiMag 222, and will withstand constant working temperature of over 1300° C.

The insulating separators (**16**) are shorter than the conductive segments (**14**), allowing for the field emitters (**17**) to be fastened outboard of the separators. The field emitters are thus located around the outer circumference of the rotor assembly and should be formed of a sintered refractory composite, such as tungsten-copper, selected for its relative surface work function and superior arc-erosion characteristics. As can be seen in FIGS. **5**, **6***a*, and **6***b*, the field emitters are fastened mechanically and electrically to the conductive segments (**14**) through locator pins (**19**), which fit into mating holes recessed into the ends of the segments. These emitters (**17**) taper to a somewhat rounded edge at the tips (**20**) which form the outermost periphery of the rotor (as an assembly), and are squared-off at their bases (**18**) to fit tightly against the insulating separators (**16**). From the top view of FIG. **6***b*, it can be seen that the field emitters follow the tapering of the segment separators (**16**), increasing slightly in width from their bases (**18**) to the tips (**20**). The conductive segments (**14**), in contrast, are of constant width over their length.

Overall Description of the Primary Power System Structure

Rotor Drive and Positioning Assemblies

Referring now to FIG. **15**, a split-frame centrifuge-style carrier assembly reminiscent of the rotatable mounting arrangement for the turntable of a carousel may be employed to firmly suspend, center, and rotatably mount the composite rotor assembly about its inner circumference within the evacuated induction compartment of the housing, and such carrier assembly should preferably be constructed of a weldable nonmagnetic metal alloy which is suitably insulated from the electrically energized rotor assembly components.

The rotatable carrier assembly may be mechanically-affixed and/or welded to one or more large metal ring gear(s) which may be comprised of like sections (**163**) to facilitate construction and which in turn may be supported, driven, and dynamically braked by one or more low-voltage DC motor-generator unit(s) (**161**) (similar to those used in large electric trains) and drive pinion gear/s (**162**). Such ring gear(s) may additionally be supported by pinion gear and pillow block bearing assemblies (if necessary—not shown in FIG. **15**). Such drive motor-generators(s) (**161**) and said pillow block bearing assemblies (if any) must be separately and nonrotatably affixed to the relatively stationary housing superstructure.

Referring still to FIG. **15**, it can be seen that in the preferred embodiment the inner end of each rotor segment (**14**) and segment separator (**16**) is flared outward into a retaining "fantail" (**160**). These retaining fantails are preferably enclosed and prepared for connection into a driven assembly using a system of: [i] insulating inner (**171**) and outer (**173**) ceramic thermal spacers; [ii] axial (**172**) and radial (**174**) nylon (or equivalent) load buffers; and [iii] insulating displacement (**170**) and lockdown (**175**) ceramic bushings. The retaining fantails are then secured into a driven assembly by two identical carrier half-structures comprising frame struts and members (**168**) and retaining ring sections (**167**), using: [i] mounting ring sections (**164**) each having two ring gear sections (**163**) attached thereto;

[ii] a corresponding number of mounting ring spacers **(165)** each having a very stiff metallic flexor plate **(166)** attached thereto; and [iii] nylon (or equivalent) torsion buffers **(169)**. The drive pinion gears **(162)** allow a preferred total of 32 like and evenly-spaced DC drive motor-generator units **(161)**, which are mounted to the Generator's ground frame **(10)**, to apply input rotational torque (or counter-rotational braking torque) to the composite rotor assembly by engaging a total of four ring gears (comprised of sections **(163)**) which are mounted to the rotor's described drive carrier assembly.

Rolling bearing assemblies should be employed to further center and stabilize the composite rotor about its outer periphery within the evacuated induction compartment of the housing, as a readily feasible mechanical alternative for that purpose to 'zero-friction' electromagnetic positioning systems (of the type normally associated with mag-lev train technology) which are of a much greater complexity.

Such rolling bearing assemblies may comprise two complimentary pairs of stationary and rotating circular-groove raceways **(25)** about the outer periphery of the composite rotor assembly, as well as an appropriate number of bearing balls **(26)** including uniform ball separation means, and these bearing assemblies may be composed of nonmagnetic stainless steel and/or a specialized ball bearing ceramic (such as silicon nitride (Si_3N_4)) which may run unlubricated in a very hot electrically-charged environment

The Rotor and Associated Elements

There are a number of electrical structures attached to the base rotor construction, which rotate with the segments, separators, and field emitters as a composite assembly. It will be understood that the structures mounted on the rotor and those interacting with the rotor are symmetrical above and below the incorporating device's equator, as well as either continuous or repeating in placement around the device in the plane of the rotor segments, so that a reference to an element at one point above the rotor also applies to the similar elements below and around the rotor.

Referring to FIGS. **1** and **2**, and in the preferred three-stage embodiment of the invention suitable for an aerospace vessel (as shown schematically in FIG. **9**), the following elements of the principal electrical generating means are mounted upon the annular rotor. Generally starting at the outer circumference of the rotor and working inward, and, for each structure, starting at the rotor and working upward, these are:

[a] the ballast capacitor, comprising a negative ring element **(22)** attached directly to the rotor, a dielectric layer **(23)** affixed thereto, and a positive ring element **(24)**;

[b] the bearing ballrace **(25)**, within which the bearing balls **(26)** roll between two identical raceway halves—one on the rotor, and one mounted to the vessel's stationary structural frame. The ballrace **(25)** and bearing balls **(26)** support the rotor peripherally and are structurally mechanical, not taking part in the electrical operation of the invention;

[c] the voltage-induction diode ring array, in the form of a cathode ring **(28)** which is mounted on and electrically connected to the rotor segments **(14)** and an anode ring **(29)** which is affixed plane-parallel to the cathode ring **(28)** and insulated from it by a suitable supporting structure using insulating posts, pins, or brackets in or on the segment separators **(16)**. Although the resulting combination could be thought of as a 2-element or diode vacuum-tube construct and is similarly named, it is more accurately a "cold" parallel plate capacitor of high value and appreciable AC conductance which preferably exhibits a modest circuit DC leakage current;

[d] the outer field coil **(35)**, helically wound and supported upon a continuous coil support or structural core which is preferably nonferromagnetic (not shown). There are preferably two windings on the core which together comprise such coil, as will be discussed in the circuit section below and as is shown in FIG. **9**—the major portion or field winding **(81)**, and a minor portion or bias winding **(82)**;

[e] the outer voltage-transfer triode ring array, in the form of cathode **(30)**, control grid element **(31)**, and anode **(32)** rings or elements, affixed plane-parallel or radially-concentric above the rotor segments **(14)** and insulated from them and from each other by similar such supporting structure (using insulating posts, pins, or brackets) in or on the segment separators **(16)**. This combination also comprises a triode vacuum-tube construct with controllably variable AC conductance;

[f] the center field coil **(40)**, helically wound and supported upon a continuous coil support or core of the type described. There are again two windings on the core, as will be discussed in the circuit section below (and as is shown in FIG. **9**)—the major portion or field winding **(83)**, and a minor portion or bias winding **(84)**;

[g] the inner voltage-transfer triode ring array, in the form of cathode **(51)**, control grid element **(52)**, and anode **(53)** rings or elements, affixed plane-parallel or radially concentric above the segments and insulated from them and from each other by the described supporting structure(s). This combination again comprises a triode vacuum-tube construct with controllably variable AC conductance;

[h] the inner field coil **(56)**, helically wound and supported upon such continuous coil support or core. There are once again two windings on the core, as will be discussed in the circuit section below and as is shown in FIG. **9**—the major portion or field winding **(85)**, and a minor portion or bias winding **(86)**;

[i] the voltage-induction triode ring array, in the form of an anode ring **(61)** which is mounted on and electrically connected to the rotor segments **(14)** as well as a cathode ring **(59)** and control grid element ring **(60)** affixed plane-parallel to the anode ring **(61)** and insulated from it and from each other by the said supporting structure(s). The resulting combination comprises a triode vacuum-tube construct with controllably variable AC conductance;

[j] the primary induction anode ring **(68)**, which is also mounted on and electrically connected to the rotor segments **(14)** and which provides the positive element of the stationary plane-parallel electrode systems used to induce the exterior field; and

[k] the ring gear(s) **(8)** or other appropriate means for allowing a drive mechanism to spin the rotor.

Field Coils

Referring now to FIG. **1**, the field coils **(35)(40)(56)** which comprise the major rotating portion of the primary DC voltage generating means are formed of conductive insulated magnet wire multi-layer toroidally wound upon cores (not shown) whose permeability should generally be minimized, and main portions of the DC voltage outputs of the three field coils comprising each of two like groups thereof—one above the plane of the rotor and one below—are sequentially connected via a plurality of individual systems of rotating plane-parallel electrode rings (or alternatively, modular radial electrode element systems or tubes) in the preferred three-stage rotor emodiment of the invention shown. The number of wire turns comprising each such field coil should in general be maximized (in a practical manner), in either the single- or three-stage embodiments.

As is depicted more clearly in FIG. **8**, each such field coil may be compound wound or comprise two or more independent voltage generating portions, with either all or the major portion of each coil constituting the field winding **(81)(83)** or **(85)** or principal DC voltage generating portion of that coil as a whole, and the principal or field winding portions of the field coils comprising either of the said two like groups thereof may be hooked in series one to another by direct physical connection in the single-stage rotor embodiment of the Generator shown. Each of the two like sets of three such field windings thus formed are then connected on their respective sides of the rotor between the plate resistor **(91)** of the diode array anode ring **(29)** and the inner triode array cathode ring **(59)**, while observing appropriate conventions of polarity assignment.

The remaining minor portion (if any) of each field coil may comprise one or more independent bias and/or control winding(s), or secondary DC voltage generating portion(s) of that coil as a whole, with the largest such secondary winding if any constituting the control grid bias winding of that coil. As shown in FIGS. **8** and **9**, one such bias winding **(82)(84)** or **(86)** is provided for each field coil and is positioned in the schematic(s) immediately thereabove. In the single-stage rotor embodiment of FIG. **8**, these bias windings are also directly connected in series one to another between the inner triode array cathode ring **(59)** and the corresponding grid resistor **(90)** of that same array's control grid **(60)**, with the negative end of each bias winding toward the said grid resistor.

In the three-stage embodiment of FIG. **9**, the field winding of each said field coil is connected in series between the plate resistor **(92)** attached to the anode ring of the outerlying electrode system which is adjacent to that coil and the cathode ring of the innerlying electrode system adjacent thereto, while observing appropriate conventions of polarity assignment. The bias winding (if any) of each said field coil is then connected between the cathode element **(30)(51)** or **(59)** of such innerlying electrode system and the grid resistor **(90)** attached to the negative control grid **(31)(52)** or **(60)** (respectively) of that same electrode system, while observing appropriate conventions of polarity assignment, such that said bias winding is in parallel with the cathode ring or element of that electrode system and may therefore provide an AC and/or DC voltage bias with respect thereto in the manner associated with electron vacuum tubes.

Rotating Electrode Arrays

Electron vacuum tube design, construction, and operating methods are employed to impress the principal portion of each field coil group's combined series DC voltage output across the Generator's rotor in an opposed parallel arrangement (comprising two like field winding circuits or rotor subcircuits), such that the rotor segments become electrically polarized, although the rotor is not considered uniformly energized electrically until a finite DC Primary Power System circuit current is established against the series capacitance and high bias voltage of the several rotor-mounted electrode systems.

Two special pairs of highly-capacitive electrode rings **(22)(24)** seperated by a dielectric media **(23)** are affixed upon the polarized rotor **(6)** near the outer negative periphery thereof, and supplied with a portion of the Generator's positive primary DC output voltage, in order to accomplish the storage of a predetermined amount of ballast electron charge which is sufficient to enable a desired much-higher secondary voltage to appear across the neutral sections of the housing (given the static capacitance and surface charge density characteristics of the housing as a whole in operation).

Electron vacuum tube design, construction, and operating methods may be employed to induce and/or modulate a substantial DC bias upon the plate currents of any or all of the various rotating plane-parallel and/or radial electrode systems or "arrays" employed in the present invention. Each rotating three-electrode system or triode array so-employed should be constructed in such a manner that it exhibits a minimum design amplification factor (μ) equal to 4.0, with reference to any AC voltage or signal present in its electrical circuit and as a function of its engineered relative electrode spacing(s).

Electron vacuum tube design, construction, and operating methods may furthermore be employed to induce, modulate, and/or amplify a minor pulsed unidirectional or alternating voltage upon the high-energy DC rotor current, and therefore on the field envelope current as well, as a means by which the electrodynamic field produced by the Generator may potentially be used (as a form of antenna) for purposes of transmitting and receiving a variable electromagnetic and/or gravimetric resonant frequency signal either to or from itself or a separate similar device (as the case may be).

In light of this teaching, it is contemplated that one possible type of communications signal which might be investigated employing the EDF Generator would couple the electric, magnetic, and gravitic forces to utilize the wave mechanics of quantum potential vacuum fluctuations ($\Delta E_q/\Delta t$), which are believed by some theoretical physicists to propagate at c^2 in order to explain the uniform operation of gravity and entropy in two space-time continuums which are coincident but completely out-of-phase. Should this quantum gravity theory prove correct, the transmission delay of a gravimetrically-coupled EM signal at this wave speed would be only 0.10525 seconds per light-year.

In any event, it should be noted that the rotor interstage coupling transformers **(89)** which are depicted in FIGS. **1** and **9** (but are not shown in FIG. **2**) would be employed only in a preferred three-stage rotor embodiment, and mounted (one each) immediately above the rotating diode and transfer triode arrays (**(28)**–**(29)**, **(30)**–**(32)**, and **(51)**–**(53)** respectively). These transformers may preferentially take the form of continuous toroid coils on either powdered iron or nonmagnetic cores (like the field coils), having single-layer primary and secondary windings, or of one or more pairs of balanced toroidal arc-section coils and cores of similar composition which are uniformly distributed above said rotating arrays. Each transformer **(89)** uses two DC blocking capacitors **(88)**.

It may be appreciated from FIGS. **8** and **9** that each bias winding or series group thereof, its associated triode array, and a corresponding output plate resistor **(91)** or **(92)** together comprise one stage of amplification of any AC signal voltage which may be present across that triode's grid resistor **(90)** as an input. In this way, electromagnetic waves of one form or another from outside the external field created by the Generator may be both detected, from their influence on the waveform(s) of the field envelope current, and amplified from within the device (when used as an aerospace vessel).

The Interaction of the Rotor and Frame-mounted Elements

Magnetic Rings

A plurality of circular arrays of stationary permanent magnets essentially comprise the stationary portion of the primary DC voltage generating means, and each such magnet is preferably to be formed as a C-shaped ring composed of axially round stock of a metallic ferromagnetic substance which exhibits a very high residual induction (such as the alloy family commonly known as Alnico). The number of individual magnetic rings comprising each such array should in general be maximized (in a practical manner). Preferably, each magnet array has a rigid and annular nonmagnetic round core (not shown) which is roughly equal in minor diameter to the inside diameter of the constitutent rings, such that the rings may be easily strung thereupon rather like beads on an abacus wire.

Referring once again to FIGS. **1** and **2**, each of the several magnetic ring arrays **(34)(39)(55)** may be installed in sections which are preferably equal in number to the number of like sections into which the incorporating device's superstructure is divided. The rotating field coil **(35)(40)** or **(56)** associated with each such circular array of individual magnetic rings must be respectively concentric and adjacent thereto, and is basically positioned on both the radial and axial centerlines of the flux gaps of that array's constituent rings. As power is generated thereby, these rings may need periodic replacing.

The maximum length of the flux gap of each such C-shaped magnetic ring must of course be just slightly larger than the minor outside diameter of its associated field coil, and should be roughly equal to or just slightly less than the formed inside diameter of that magnetic ring. In the preferred embodiment these ring flux gaps are oriented horizontally, although they may also be readily oriented vertically if so desired. Each magnetic ring may also be mounted within the superstructure of the housing such that a comparatively small thin axially-polarized wafer of a highly-coercive permanent ferromagnetic substance (like sintered Ferrite 5 ($BaO.6Fe_2O_3$)) is positioned in the hollow center of that ring magnet, with such wafer's magnetic poles facing the like poles thereof, so as to act as a leakage flux blocking or reducing mechanism with respect thereto. These optional components would be most easily installed by insertion into a corresponding slot cut into each of the described mounting cores, and are recommended for use in very large devices.

Also arranged concentrically around the evacuated induction compartment **(12)** of the Generator, but fixedly mounted within the vessel's structure instead of rotating with the rotor assembly, are the following elements of the principal electrical generating means. Again, they are discussed in order from the outer circumference of the vessel inward, as shown in FIGS. **1** and **2**, and a reference to an element at one point above the rotor also applies to the similar elements below and around the rotor:

[a] the stationary half of the ballrace **(25)**;

[b] the outer array **(34)** of stationary permanent magnets, which should be mounted on a nonmagnetic core and in the preferred embodiment incorporates a maximum of 900 such ring magnets equally spaced around the vessel superstructure;

[c] the circular group of stationary electromagnetic armatures **(37)** or "variable inductor" array, as used to impart a rotational magnetic force upon both the external discharge current and the internal rotor assembly (which is proximal thereto). Each such array preferably comprises a maximum of 180 such armatures, and is to be approximately centered within the neutral region of the housing so that its constituent armatures are axially parallel to the rotor's axis of rotation;

[d] the center array **(39)** of stationary permanent magnets, which should be mounted on a nonmagnetic core and in the preferred embodiment incorporates a maximum of 720 such ring magnets equally spaced around the vessel superstructure;

[e] the inner array of **(55)** stationary permanent magnets, which should be mounted on a nonmagnetic core and in the preferred embodiment incorporates a maximum of 576 such ring magnets equally spaced around the vessel superstructure; and

[f] the stationary anode ring **(58)**, located adjacent and plane-parallel to the rotating cathode **(59)** of the inner electrostatic-induction triode array, which develops an induced positive voltage that is made available to the control circuitry shown in FIG. **10** as described below.

FIGS. **8** and **9** show two embodiments of the Primary Power System. The "Field Induction System" or stationary plane-parallel electrode arrangement(s) employed to induce the exterior field is/are basically the same in either case, and the voltage control system of FIG. **10** may be used with either embodiment.

The simpler single-stage rotor system of FIG. **8** is primarily intended for applications wherein the EDF Generator would be employed to produce useful electricity or heat, the latter being extracted from a principal liquid hull coolant circulated through the primary thermal conduits **(48)** (shown in FIG. **1**) that encircle the field power resistors **(63)**. Two thermal exchange or main service manifolds (not shown) would provide ground-based support to such a Generator from an associated utility or physical plant, as well as a remarkable level of electrical or thermal output from such Generator thereto. Each such manifold would connect directly to a single circular center sector of one of the two positive housing zones. Each of these two center sectors **(44)**, one or either of which is depicted in FIG. **4**, must in this case be composed of a nonconductive material.

Description of the Primary Power System Circuit

Referring again to FIG. **8**, the respective outer, center, and inner field windings **(81)(83)(85)** are directly connected in series, and the voltage thus generated is applied to the inner induction triode array cathode ring **(59)** and (through plate resistor **(91)**) to the outer induction diode array anode ring **(29)** and to the ballast capacitor anode ring **(24)**. The respective outer, center, and inner bias windings **(82)(84)(86)** are also connected in series, and the voltage thus generated is applied between the inner induction triode array cathode ring **(59)** and (through grid resistor **(90)**) to the control grid **(60)** of that same array. This places said control grid in parallel with that cathode electrically.

The turns numbers of the bias windings **(82)(84)(86)** and the grid resistor **(90)** values are chosen to apply a bias voltage to control grid **(60)** such that the inner induction triode array is biased very nearly to current cutoff. This results in a very high voltage being induced on the rotor segments **(14)** between outer induction cathode ring **(28)** and inner induction anode ring **(61)**, but at a very low series field coil current due to the near-cutoff bias of the triode array. It is expected that the voltage on the rotor segments between these two rings, in a preferred embodiment using this arrangement, would be approximately 8,000 volts for a four-foot diameter prototype, or about 2,000 volts per foot of housing diameter. It is also anticipated that series field coil current could be limited to fractional amperage in smaller such devices and to single-digit amperage in the largest.

The preferred embodiment shown in FIG. **9** is a three-stage rotor system which is considered to be much more useful for applications wherein the EDF Generator may be employed as an aerospace vessel, in that it allows energy/wave-function signals from outside the vessel to be detected and amplified in the manner previously described.

In this embodiment, instead of the field windings **(81)(83)(85)** being directly connected together in series, intermediary voltage-transferring triode vacuum tube constructs are used to effect an indirect series connection between the said field windings. The voltage thus generated is again applied to the inner induction triode array cathode ring **(59)** and (through plate resistors **(92)**) to the outer induction diode array anode ring **(29)** and to the ballast capacitor anode ring **(24)**. The bias windings **(82)(84)(86)** are in this case used to provide an independent bias voltage to the control grids **(31)(52)(60)** of the outer, center, and inner rotating triode arrays, respectively, in parallel with their cathodes.

As in the single-stage rotor embodiment described above, the turns numbers of the bias windings **(82)(84)(86)** and the grid resistor **(90)** values are chosen to apply a bias voltage to control grids **(31)(52)** and **(60)** respectively such that each corresponding triode array is biased very nearly to current cutoff. This results in a very high voltage being induced on the rotor segments **(14)** between outer induction cathode ring **(28)** and inner induction anode ring **(61)**, again at a very low or fractional current due to the near-cutoff bias of the triode arrays. It is expected that the voltage on the rotor segments between these two rings, in a preferred embodiment using this arrangement, would be approximately 1,500 volts per foot of vessel diameter.

In general, the stationary anode rings **(58)** and all of the rotating electrode rings except the primary anode rings **(68)** should be composed of a nonmagnetic structural nickel alloy (such as Inconel 600). All rotating control grid element wires should be composed of an alloy such as that commonly known as nichrome. The rotating cathodes may be composed of modestly-thoriated tungsten, however, if and only as necessary to establish a small DC Primary Power System current if the observed 'dark discharge' current values are deemed insufficient, particularly in the three-stage embodiment wherein amplification of a minor AC signal voltage may be desired for communications purposes. The ceramic material Titania, with a nominal dielectric constant of 85, may preferably be used to form the posts, pins, or brackets which support the various rotating electrodes.

It is important to observe that both Primary Power System (rotor) field winding circuits as configured in both the single- and three-stage Generator embodiments will have an inherent AC series resonant frequency, and operation at that frequency will maximize the series field winding AC line currents (within given circuit resistor constraints) as well as the dependent stage plate voltage drops (across resistor(s) **(91)** or **(92)** respectively) which allow stage AC signal reproduction and amplification. As in traditional related practice, the series resonant frequency will be that at which the given circuit's inductive and capacitive reactances are approximately equal and opposite. Thus, the series resonant frequency of either of said Generator rotor circuit embodiments will be largely contingent upon the total field winding inductance and coil core permeability, as the various rotor electrode arrays and the plate resistor(s) **(91)** or **(92)** must have quite specific fixed relative design values of capacitance and resistance (respectively)—as a function of total field winding voltage—for proper overall DC and AC circuit performance.

Each Primary Power System control grid winding subcircuit as configured in the three-stage rotor embodiment may then be readily tuned for stage AC parallel resonance at the said inherent series resonant frequency, thereby minimizing stage grid subcircuit line current while maximizing the stage grid voltage drop (across each grid resistor **(90)**) which determines the level of net stage AC signal voltage gain or amplification obtained. As in traditional related practice, the parallel resonant frequency will once again be that at which the given subcircuit's inductive and capacitive reactances are approximately equal and opposite. This condition may be achieved by connecting an optional capacitor of suitable value if desired across the secondary winding (or control grid resistor side) of each rotor stage coupling transformer **(89)**, as indicated in FIG. **9**.

The Field Induction System

Before commencing a technical discussion of the stationary induction electrode systems which will be used to charge the positive housing sections, it will be necessary to further elucidate certain aspects of the Primary Power System electrical circuit so that a few of its key operational characteristics are more clearly understood.

Referring now to FIG. **7**, each of the Generator's two identical groups of rotating field coils (one above and one below the rotor) are in essence connected in simple series across the rotor segments using pairs of capacitive electrode rings, thus forming a single series loop with respect to the rotor. The two such series loops are at the same time, however, connected in mutually-opposed electrostatic parallel with respect to the rotor segment circuit leg common to both such loops.

Based on applicable principles of proper circuit resolution and series DC capacitance, such an opposed series-parallel circuit may readily be configured such that equal and opposite-polarity voltages will result upon the rotor-mounted induction cathode **(28)** and anode **(61)** rings in the absence of a fixed ground reference. To this end, the rotor assembly itself is to remain completely without direct earth or chassis ground in operation, and a corresponding segment polarization will continue as the circuit is duly energized by a finite DC conduction current.

When a primary DC rotor current is also established to the housing's Emitter Ring **(47)** and an external discharge current in turn occurs to the positive zone sectors **(42)**, the two systems of primary induction electrodes **(64)**–**(68)** also complete two simple series loops back to the rotor and the two such external field envelope subcircuits in parallel constitute the EDF Generator's "Field Induction System" circuit. Thus, the total field discharge current equals the primary rotor current, and the rotor segment circuit leg is common to both of the major system circuits described.

As is apparent from the section on Method of Operation, it is imperative that the charged housing sections also have no direct earth or chassis ground, being instead of a 'floating-ground' reference with respect to the described primary rotor circuit. The cathodes **(64)** of these two primary electrode systems may have a chassis ground reference at a very high resistive bias (as indicated in FIG. **10**), across which any actual cathode charge imbalance or potential in operation may be detected and measured.

Therefore, in light of the Faraday shielding principle and the said equal and opposite voltages which occur at opposite ends of the rotor segments (**14**), the potential difference between the rotor field emitters (**17**) and the inner surfaces of the two negative hull sections (or Emitter Ring (**47**)) will tend to become equal (and opposite) in operation to that across the primary electrode systems. And thus, a suitably vast and engineered differential in the electron emissivity of the field emitters (**17**) and the said ground-referenced primary cathodes (**64**) will define the primary voltage expansion ratio which may be obtained (in the manner first outlined in the section on Method of Operation). This topic will be discussed in more detail in a section to follow.

Moreover, a basic field-envelope-circuit generator design is disclosed which thus far, in accordance with Faraday's and Lenz's Laws, can produce a very high DC primary voltage with minimized circuit AC current inductance losses. The Primary Power System's DC voltage is not readily available, however, for purposes of normally-usable electrical output. Brushless electrode rings (**58**) must once again be employed to extract any portion of this primary voltage for off-rotor use. The Primary Power System schematics shown in FIGS. **8** and **9** in conjunction with FIG. **10** best illustrate the use of these two additional stationary anode rings (**58**), one suspended adjacent to each inner rotor induction cathode ring (**59**), which allow a large electrostatically-induced positive DC voltage to be 'picked off'. This positive voltage may then be used as a source of low power within an external circuit, provided that circuit is negatively-grounded and only to the Generator's chassis, and is therefore really intended for auxiliary onboard usage only.

It can be seen thus far, and especially in FIG. **7**, that there are essentially two major systems involved in creating the voltages which must be applied to the positive and negative housing or hull sections in order to form the electrodynamic field that will surround the Generator in operation. These two systems are:

[A] the Primary Power System, which generates a large DC voltage by electromagnetic induction and then electrostatically induces a major portion of that voltage upon the rotor segments (**14**) between two pairs of induction anode (**61**) and cathode (**28**) rings which are conductively affixed thereto (about the inner and outer circumferences of the rotor assembly, respectively); and

[B] the Field Induction System, which utilizes the potential difference which then exists between the positive inner circumference of the rotor—and its two attached primary anode rings (**68**)—and two separate sets of highly electron-emissive stationary cathodes (**64**) which are maintained at chassis ground and which are circularly-arranged near and electrically-connected to the periphery of each central collector housing section (or "zone") so that they may jointly charge their respective zone sectors (**44**) and/or (**42**) positively by stripping them of native electrons.

Each of these primary electrode array cathodes (**64**) connect directly to a field power resistor (**63**), which in turn connects to one positive radial zone sector (**42**) of the central housing sections. Each such cathode (**64**) is also vertically aligned inboard with a group of three stationary plane-parallel grid electrode elements and one of the two innermost rotating induction anode rings (**68**) conductively-affixed to the rotor segments (**14**) (about their positive inner circumference). Each such group of three grid elements is comprised of a control grid (**65**), an accelerator grid (**66**), and a suppressor grid (**67**), with one such combined grid element assembly per radial zone sector (**42**).

Together with the said primary induction anode ring (**68**), each such 5-electrode group constitutes what is termed a "unit pentode array" ((**69**) as seen in FIG. **7**). The unit pentode arrays (**69**) and their associated frame-mounted power resistors are thus arranged in two ring-shaped sets, located between the rotor and the two positive housing sections, which are referred to throughout as the "primary induction ring rays".

The potential difference between the unit pentode array cathodes (**64**) and rotor primary anode rings (**68**) is then referred to as the "primary array voltage", as the unit pentode arrays of each primary induction ring array are connected in parallel electrically (between the field envelope and rotor), and the number of unit pentode arrays should be equal to the number of like sections into which the Generator's superstructure is divided.

Electron vacuum tube design, construction, and operating methods may be employed to induce and/or modulate a substantial DC bias upon the plate current(s) of the several unit pentode arrays, which electrically link the polarized rotor to the central housing sections, for purposes of rendering the external electrodynamic field variably non-isometric and therefore directionally propulsive. Each such "stationary" 5-electrode system or unit pentode array (**69**) (whose anode element actually rotates) should be constructed in such a manner that it exhibits a minimum design amplification factor (μ) equal to 12.0, again with reference to any AC voltage or signal present in the Field Induction System circuit and as a function of its engineered relative electrode spacing(s).

The rotating primary induction anode rings (**68**), stationary cathodes (**64**), and various grid element wires which are associated with the stationary multi-electrode systems should be composed of tungsten, due to the extremely heavy conduction current across these primary arrays. Ceramic posts, pins, or brackets composed of a specialized material such as Titania may once again be used to support all of the various stationary electrodes and grid elements, and each unit pentode array's grid wires should be vertically aligned (or mutually-shading) similarly to those in a "beam power pentode" vacuum tube.

As generally depicted in FIG. **1**, a primary thermal conduit (**48**) with an imbedded coolant-carrying core (**49**) encircles and mechanically supports each unit pentode array, its power resistor (**63**), and that resistor's enclosing dielectric buffer (**45**). These thermal conduits and dielectric buffers will be examined in further detail hereinafter.

The operation of the Field Induction System is regulated by a central Field Voltage Control System which is modular in nature, as illustrated in FIG. **10**, and which is therefore mechanically and electrically connected to the stationary cathodes and grid elements of each unit pentode array (**69**). In this regard, the auxiliary stationary anode rings (**58**) described above are to serve as the source of positive voltage applied to the accelerator grids (**66**) of said unit pentode arrays, and such Field Voltage Control System is designed to directly accept this voltage for that purpose. The Field Induction and Voltage Control Systems will be discussed further in sections to follow.

Zone Sector Construction

Referring now generally to FIGS. **3** and **4**, one major goal in dividing each of the two hull positive zones or sections (**5**) which jointly comprise the Generator's Field Hub into a large number of radial sectors (**42**) in electrical parallel is to limit the external field current reaching each particular power resistor and unit pentode array combination to a fairly uniform level, while somewhat reducing field current return eddy losses as well. However, each radial sector (**42**) is thereby also given the capability of effecting a local thrust production differential (in propulsive three-stage rotor devices), by virtue of its electrical isolation, as it is then possible to vary the local resistance presented to the electrodynamic field with respect to any given radial sector so that a substantial measure of navigational control in the z-axis may thus be achieved by varying the proportional field current conducted by that sector.

Because the inherent resistance of each such sector itself will be negligible even at an extremely elevated operating temperature, in part due to the very low temperature coefficient of resistivity of the proposed steel hull plate material, the voltage drop across the radial length of each sector will also be negligible. Thus, the determination of an appropriate sector thickness becomes an entirely structural consideration. A secondary design goal with respect to zone sectorization is therefore to select a uniform cross-sectional area for the radial zone sectors (**42**) which yields a Field Hub total conduction mass approaching that of the device's rotor segments (**14**).

The hull plating which forms each positive zone (or section (**5**)) of the Generator's Field Hub should preferably be composed of stainless steel or a refractory metal, and divided into thirty-six equal-area radial zone sectors (**42**) of truncated wedge shape and a circular center zone sector (**44**). As stated earlier, in the single-stage Generator embodiment these two center zone sectors must be of a nonconductive material or construction, and should also comprise approximately 4 to 5% of the total area of their respective zones to allow the connection of the exchange or main service manifolds described above. In the three-stage embodiment such center sectors (**44**) must instead be conductive as just prescribed for the radial zone sectors (**42**), and should each comprise about 1% of the said zone area. Each such positive radial sector should be formed of a single piece of the hull plating material in such a manner that its cross-sectional area in the direction of its radial length is maintained at a very uniform value.

The uniform thickness of each center zone sector (**44**) should be equal to that of the radial sectors as measured at the minor (inner) arc width thereof, and the radial sectors must be insulated from the respective center sector where they meet that center sector's periphery (except in single-stage rotor devices). A suitable thin ceramic insulating partition (**43**) may therefore be installed between each adjacent pair of radial zone sectors (**42**), and around each center sector (**44**) in three-stage devices, and the uniform flat thickness of these sector insulators should in general be minimized.

In three-stage devices, four radial sectors (**42**) of each positive housing zone which correspond to cardinal points separated by 90 degrees of the hull's circumference, and which divide the Field Hub into four equal quadrants (as indicated with phantom lines in FIG. **4**), should be connected in parallel with the center sector of that positive zone at the maximum positive voltage end of those four sectors' respective power resistors (**63**).

The parallel resistance of the four conductors which therefore connect each center zone sector (**44**) (in three-stage devices) to its respective network of power resistors should then be such that that sector's per unit surface area level of field current conduction is slightly higher on the average than that of its adjacent radial sectors (**42**), under uniform zero-signal field bias conditions as hereinafter described.

The four unit pentode arrays (**69**) of each primary induction ring array which correspond to the power resistors so-connected to that primary array's center zone sector (**44**) would generally not be utilized individually in the active field current bias modulation related to the production of local thrust differentials (in three-stage rotor devices), being instead reserved primarily for potential involvement in signal communications transmission and/or reception activities.

Power Resistors

As best seen in FIG. **1**, the cathode element (**64**) of each plane-parallel electrode system or unit pentode array which is used to link the rotor assembly with a positive housing collector section or radial zone sector (**42**) is electrically connected to such positive section or sector by means of a ceramic resistor block (**63**), of a certain low dielectric constant and high volume resistivity, which becomes a poor but effective conductor at the elevated operating voltage and temperature of such housing collector sections and which ensures an adequate external field current voltage drop between such section or sector (**42**) and said cathode element (**64**) (which is chassis-grounded as shown in FIG. **10**).

Referring still to FIG. **1**, each said ceramic resistor block or "power resistor" (**63**) is to be entirely jacketed by a hollow ceramic thermal conduit (**48**), including a dielectric buffer (**45**) composed of a ferroelectric material having a certain high dielectric constant and very high volume resistivity which does not become a conductor even at the elevated operating voltage and temperature levels of said power resistors. These thermal conduits (**48**) mechanically connect the power resistors to a flattened inner surface of such positive hull section or radial sector (**42**) and a form of very-high-temperature heat transfer fluid such as liquid sodium may be circulated therein so that the proper resistor temperature is maintained to ensure an optimum cathode potential with respect to ground.

A suitable manifolding, pump, and heat exchanger system (not shown) may be used to extract or transfer an extremely high level of recoverable thermal energy from the power resistors (**63**), arising from the field current voltage drop associated therewith, by means of such primary heat transfer fluid circulated through the thermal conduit cores (**49**) in the manner normally associated with nuclear power plants. Similarly, the rate at which such primary hull coolant is circulated may be used to directly regulate and limit the external field current to a value within the safe ampacity of the rotor assembly.

It is important to point out that each of the Generator's power resistors (**63**) and its associated dielectric buffer (**45**) and primary thermal conduit (**48**) may be designed, as an assembly, to incorporate a fixed positive reduced-voltage tap (not shown), whereby a main source of onboard or output DC or AC electrical power may be provided either for or from the Generator within a limited-duty circuit which is grounded directly to the primary cathodes. Provisions should and may also be provided for biasing, damping, and/or inductively coupling any primary conduit connecting sections, to control or harness electromotive currents induced in the highly-conductive primary coolant. Onboard electrical resistive heating means should and may be incorporated for purposes of pre-heating the primary coolant and, in turn, the power resistors and dielectric buffers.

Referring briefly to FIG. **11**, it is also important to note that the Generator's power resistors must be in a conductive state before the housing potential difference reaches breakdown field intensity, as figured along a minimum semicircular arc trajectory (**142**) across the hull neutral sections (**4**), and the flow of field discharge current commences. Therefore, the actual maximum dielectric constant of the resistor material used in very-high-voltage single-stage rotor devices, and in ultra-high-voltage three-stage rotor devices as well, may be calculated at about k=11.

As is best seen in FIG. **14**, the recovery thermal conduits (**79**) of the secondary hull coolant system which assist in supporting the entire tapered peripheral portion of the housing must pass inboard between the power resistor assemblies referred to above, and therefore the resistors (**63**) must assume a complex tapered shape to provide the necessary clearance. As generally depicted in FIGS. **1** and **2**, they will have a trapezoidal cross section at the 'top' or outward-facing end (with radial length somewhat greater than minor circumferential width) and a rectangular cross section at the bottom or cathode end (with circumferential width much greater than radial length). In this regard, their engineered shape should still maintain a uniform conduction cross section exactly analogous to that of the preferred positive zone sector construction described above.

Dielectric Buffers

Referring once again to FIG. **1**, it is imperative to electrically insulate the power resistors (**63**)—due to the extreme voltage drop that will occur across them in operation—to prevent direct discharge to other nearby structural components from taking place. However, not only is this a problem due to the thickness of insulation which would be required at any 'ordinary' dielectric value, but the power resistors' projected operating temperature range of 600 to 700+° C. completely precludes the use of almost all known dielectrics. Fortunately, the search for high-temperature dielectrics for use in aerospace electronics applications (particularly multi-layer capacitors) has resulted in the development of a small number of exotic materials potentially suitable for use as a space charge buffer (**156**) or dielectric encapsulant (**45**) for the Generator's power resistors (**63**).

In the application contemplated herein, the volume resistivity of the resistor encapsulant is somewhat secondary to its dielectric constant k at high temperature, because no opposing contact voltage is present (as in a capacitor) to encourage circuit conduction losses within the material. Therefore, the prime consideration is the dielectric's ability to exhibit a very large k value at over 600° C. This places the material squarely in the realm of a very small select group of Class III high transition temperature ferroelectrics. These materials, such as Tantalum-modified Lanthanum Titanate and Lead Ytterbium Tantalate, do not begin to demonstrate significant dielectric strength at less than 300 to 450° C. One such compound, Sodium Bismuth Titanate ($Na_{0.5}Bi_{4.5}Ti_4O_{15}$), actually exhibits an amazing peak k value of about 3100 near the middle of the said power resistor operating temperature range: at 655° C. (1,202° F.). This would seem to indicate that this compound is eminently suited for use in forming the necessary rotor space charge buffer pieces (**156**) and/or resistor dielectric buffers (**45**) in this application.

It should be stressed that great care in quality control must be exercised in formulating and sintering this or any similar such special compound during manufacture of the dielectric buffer pieces. An absolute minimum of impurities must be assured, the density of the constituent powder maximized, and each piece finally certified as being free of the smallest physical defect prior to use in order to attain the desired operating performance. It is also hoped that these crucial components may each be compaction die formed and sintered simultaneously with a respective power resistor (**63**), and perhaps even with the corresponding primary thermal conduit (**48**) as well.

The core (**49**) of the thermal conduit associated with each power resistor (**63**) should be constructed of a refractory metal or alloy tubing (such as molybdenum) which is jacketed with high-purity Alumina or a comparable material formed directly thereupon. Thus, each such primary thermal conduit becomes an extremely strong structural member which may also be used to support the stationary electrodes of the corresponding unit pentode array, while circulating the preferred liquid sodium heat transfer fluid or coolant around the outward faces of that power resistor to recover or remove its excess heat.

Each power resistor (**63**), its dielectric buffer (**45**), and associated primary thermal conduit (**48**) together comprise one power resistor assembly, and each such assembly in combination with its corresponding unit pentode array is considered for present purposes as forming the constituent component group of which the primary induction ring arrays and Field Induction System are comprised.

Extensive calculations reveal that a suitable power resistor material in most sizes of the single-stage embodiment of the Generator would be a ceramic material with the chemical formula $MgO.SiO_2$, which is available from CeramTec NA as CeramTec designation Steatite 357. A suitable power resistor material in most sizes of the preferred three-stage embodiment of the Generator would be a somewhat different ceramic material with the chemical formula $2MgO.2Al_2O_3.5SiO_2$, which is available from CeramTec NA as CeramTec designation Cordierite 547.

Overall Description of the Field Induction System Circuit

Before an overview of the EDF Generator's Field Induction System electrical circuit is presented, a somewhat comprehensive examination of the nature of the housing or hull configuration should be made, as in this application the hull itself is an active part of that circuit. Its electrostatic characteristics as a function of such configuration will therefore have a fundamental influence upon the nature of the external field envelope discharge current itself.

Hull Design

The derivation of the Generator's design hull configuration, as best seen in FIG. **3**, comprises a long and complicated story. This should not be taken to imply that the final and rather exacting composite shape selected is the only one that 'works' properly. It merely reflects the preferred embodiment of the inventor's conceptualization of a fundamentally mechanical device which happens to entail both tremendous electrical complexity and inspiring aeronautical implications.

Should the proposed vessel eventually be used to explore the possibility of transcending the time/light barrier, extremely precise calculations regarding its spatial displacement and charge/mass ratio will no doubt become necessary. Therefore, one of the principal reasons for the chosen hull design is that the total vessel displacement may readily be calculated using traditional formulas from analytic geometry for the volumes of the two truncated right conic sections and two one-base spheric zones, and the volume of the remaining cylindrical central chamber region.

Using just these formulas, a vessel hull configuration has therefore been developed which may be linearly expanded (as a scalar function of the hull radius) to virtually any size with no significant loss of accuracy. The Table of Dimensions which follows and the attendant schematic hull diagram of FIG. **3**, upon which all of the subsequent Detailed Calculations quoted are based, illustrates the application of this design technique to a theoretical vessel hull only 48" in diameter. It must be emphasized that the construction of an Electrodynamic Field Generator this small might not prove entirely practical in reality, due strictly to mechanical limitations, and the inventor believes this prototype model to be in fact the smallest such machine that could be built. This original hull size was deliberately selected, however, to encourage the development of the maximum possible accuracy with respect to contingent specifications for the relative size and positioning of the Generator's principal components, prior to the actual construction of larger machines.

The surface areas of the negative **(3)** and positive **(5)** hull sections are set equal to each other, and for two very important reasons: [i] to give the vessel hull a significant theoretical capacitance (despite its unusual geometry); and [ii] to render the two "driving" or discharge current portions of the field envelope uniform in cross section. Essential considerations which are related to these fundamental design criteria are best expressed in the following electrostatic formula for uniform field intensity in a DC capacitor which exhibits a continuous leakage current:

$$E^2 = V\sigma/d\epsilon_o,$$

where V=equilibrium potential difference in volts,

σ=average surface charge density of one plate,

d=plate separation in meters,

ϵ_o=universal electrostatic constant,

and E=uniform field intensity in volts/meter.

This equation plays an important supporting role in the invention's Method of Operation, as previously discussed in that section above.

The volumes of the peripheral right conic sections of hull volume surrounding the Field Hub and and those of the one-base spheric zones comprising the Field Hub itself are also set equal in a preferred embodiment, as this criterion is postulated to promote both the structural integrity of the hull in any attempt to breach light speed (and establish a stable Kerr metric space warp about the vessel) as well as the gravimetric stability of the central chamber/cabin area in light of the relativistic mass effects involved while doing so.

As the case may be, to achieve this equal-area/equal-volume design, it was found necessary to employ two crucial interrelated constants (in addition to the ratio ⅕ used to radially "step off" the hull's interior space): the Hull Area Constant and the Polar Hull Constant. The Area Constant is (as the name implies) necessary to achieve the equal-area part of the overall design solution, and merely dictates the small deviation of the neutral **(4)** and negative **(3)** housing sections' ring radii from the stated preferred design increment of the hull's radial width.

The other requisite design factor, the Polar Hull Constant, is much more complex in nature. This value specifies the maximum height of the spheric hull zones **(5)** as a function of their arc-shape, and the corresponding contingent Polar Volume Differential is absolutely essential to achieving the equal-volume aspect of the preferred design. It is important to note that certain allowances must be made in practice for a finite but electrically-significant peripheral edge 'thickness' (and therefore surface area) at the equator of the device's negative housing Emitter Ring **(47)**, but will in general only minimally modify the "pure" design-model values obtained using the mathematical formulas given in the Table of Dimensions to follow.

Hull Configuration

Referring now to FIGS. **3** and **4**, the exterior housing or hull **(1)** is designed specifically to have a circular disc shape the thickness of which along the vertical axis of symmetry (that also constitutes the rotor's axis of rotation) is relatively minor as compared to the diameter along its radial centerline plane, and which tapers gently from a maximum thickness along such vertical centerline to a very minor thickness at the radial periphery **(47)** of the housing.

The tapered disc shape of the hull is postulated to promote the formation and maintenance of a stable bihemitoroidal corona or arc discharge field based upon certain empirical principles of electrostatics and upon laboratory experiments performed by the inventor involving concentric circular electrodes. Such an electrodynamic field may be characterized electrostatically in this application by an axial positive polar electric field contiguous with a biplanar negative electric field, with each field of one given polarity tending strongly to become oriented parallel to a field of opposite respective polarity but similar intensity.

The exterior housing or hull **(1)** is therefore divided into two axially-central positive electron collector sections **(5)**, as well as: [i] either a single radially-peripheral negative electron emitter ring **(47)** which is biplanar in cross section or two or more such ring sections **(3)** which are uniplanar in cross section having separate planar orientations; and [ii] two dielectric neutral sections **(4)** which are interposed between said positive and negative sections such that each such section of a given polarity is spatially separated from each section of the opposite respective polarity.

The total external surface area of the housing's negative Emitter Ring **(47)** or sections **(3)** is essentially equal to that of the positive collector housing sections **(5)** or zones, such that the overall housing configuration thereby acquires a significant theoretical static capacitance by design as intended. An estimated base value for such hull capacitance 'C' may be obtained by applying the surface area 'A' of the hull's two sets of "plates", as figured using the formulas in the Table of Dimensions below, to the standard formula for parallel-plate capacitance ($C=\epsilon_o A/d$). When plate separation 'd' is taken to be the simple average of the longest **(141)** and shortest **(142)** purely-semicircular arc current trajectories across the hull, as depicted in FIG. **11**, this estimate of hull capacitance is approximately 13 to 14 mmf for an EDF Generator 48" in diameter.

Field Composition

Referring to FIG. **11**, the external discharge current once initiated may be expanded as a function of the operative field voltage to fill two hemitoroidal spatial volumes of rotation **(140)** whose outer perimeters **(141)** are defined by a semicircular electron arc trajectory across the full housing radius in a plane perpendicular to the housing surface, or from the outermost point on the negative periphery thereof to the respective positive centerpoint of the housing lying on the vertical centerline thereof, and whose inner boundaries

(142) are defined by a similar such trajectory across the hull's neutral ring or sections (4) from any innermost point on the negative periphery to the closest point thereto lying on the respective positive collector section (5).

The physical volume (140) of the external discharge current as described has a uniform cross-sectional area in the radial direction of electron conduction which corresponds to any such semicircular arc trajectories between points on the housing's negative Emitter Ring (47) and the respective positive collector housing sections (5) and therefore, by the definition of a conductor, such discharge current must assume a uniform current density. While very difficult to effectively describe in verbal terms, the idealized mathematical configuration of the Generator's heat- and thrust-producing field envelope region (as a function of its housing geometry) is visually easy to grasp and is clearly illustrated in FIG. 11.

As indicated in FIGS. 12 and 13, stationary electromagnetic armatures (37) are uniformly distributed into two circular arrays (145) containing equal numbers thereof which are positioned on opposite sides of the rotor from one another, and which are each located concentric to the rotor's axis of rotation midway between the negative Emitter Ring (47) and positive housing sections (5). These armature arrays (145) may be employed as two separate groups to impart a holistic but attenuating rotational magnetic vector moment upon the external discharge current, reaching through the thin neutral sections (4) of the housing, and thus may be used to modulate the field envelope's kinetic and electrical characteristics in a variety of ways useful to the invention and its objects.

FIGS. 12 and 13 also show the electric field vectors (143) as described above, and magnetic field vectors (144) as produced and modulated by the armatures (37) comprising the two armature or variable inductor arrays (145). FIG. 13 specifically depicts the regular lateral bending or displacement of the radially-impinging electron trajectories (143), under the influence of the inductor arrays (145), which is postulated to have a unitizing effect on the driving portions (140) of the field envelope.

It can therefore be seen that the device contemplated herein may be operated in such a manner that its external breakdown discharge current field achieves a uniform conductive cross section and current density, as well as a holistic and orderly rotational aspect which subsequently acts to assist in rendering such current quasi-coherent. And thus, for purposes of this device and its applications, such a discharge current field should be thought of as a special qualified type and form of DC corona or arc discharge—having significant propulsive potential (to be further examined)—which then merits technical description as an electrodynamic field.

In this respect, it may for now be emphasized that a useful level of electrically-developed thrust may be realized from the relativistic impulse of the electrodynamic field current electrons incident upon the positive collector housing sections and, postulating the operation of the device in the vacuum of space (with a physical field current volume as described), the impulse velocity of such incident field electrons may be raised to as high as 99.99% of the speed of light and more with the corresponding relativistic mass thereof then equal to 69 times their rest mass or indeed much more.

Primary Voltage Expansion Ratio

In keeping with the logic presented at the opening of the Field Induction System section above, the primary array voltage will tend to equal only one-half (½) of the DC voltage expressed across the rotor segments (or "rotor voltage"). Therefore, to develop an extraordinary multi-megavolt 'secondary' or field voltage across the Generator's housing of the type just described, the primary array cathodes' electron emissivity (expressed as a certain factor) must exceed that of the rotor field emitters by a ratio which is at least as large as the ratio of the desired field voltage to half the observed said rotor voltage. The latter such ratio is then thought of as the primary voltage expansion ratio in this application, as outlined in the Method of Operation section hereinabove.

A difference in the instantaneous rate at which these two said sets of parts will tend to discharge under the impetus of a given equivalent voltage or potential difference is thereby created. This instantaneous charge differential enables the primary cathodes to strip native electrons from the positive housing sections (5) thousands of times faster than such charge can reach the negative emitter housing sections (3) from the rotor field emitters. Thus, an instantaneous charge differential is perhaps best described as a cumulative charge imbalance that is known to operate (under certain conditions) in capacitive and/or thermoelectric circuit arrangements and to express itself as an elevation of the applied voltage or potential difference therein.

To actually achieve and support such a condition requires the use of two housing charge ballast capacitors whose negative 'plate' elements or rings are affixed directly to the rotor segments (about their outer perimeter) and which are immediately able to store an amount of such charge that is sufficient to produce equilibrium collector surface charge densities resulting in the desired field voltage. This average required housing charge density is calculated using the traditional formula given in the Hull Design section above.

The voltage applied to the positive rings of these ballast capacitors is taken from the rotor's outer field coil anode ring connections and therefore represents a large portion of the Primary Power System's generated field winding voltage. It should be noted that this voltage must actually be passed to such capacitors beneath the rotor ballrace assemblies in the form of recessed conductive traces on one or more of the segment separators. This same technique must also be employed to connect electrical elements of the Primary Power System lying outboard of the variable inductor arrays (145) with corresponding elements lying inboard thereof.

In any event, these crucial ballast capacitors are therefore properly thought of as belonging to both the Primary Power System and Field Induction System circuits. They provide the necessary electric force means by which a given primary voltage expansion ratio (as defined) may be supported and realized using the engineered instantaneous charge differential concept described. Because of the complexity of this aspect of the Generator's operation, the specific example below will illustrate the relevant principles using the respective temperature emissivity factors of the chosen field emitter and primary cathode materials with respect to the aforementioned 4ft. prototype model.

This temperature emissivity factor, $e^{-\phi/kT}$, where 'e' is the base of natural logarithms 2.71828 . . . , 'k' is Boltzman's constant, and 'T' is the absolute temperature in °K, derives from the famous Richardson-Dushman equation: a formula for the correct thermionic emission current density 'J' of a clean metal cathode in vacuum having surface work function ϕ. And, expressed in mathematical terms, the principle of ratio equivalence defined above may be stated as follows:

$$\text{Primary Voltage Expansion Ratio} \approx \text{cathode } e^{-\phi/kT}/\text{emitter } e^{-\phi/kT}.$$

Using field emitters of sintered 0.68/0.32 tungsten/copper composite and thorium-adsorbed tungsten primary cathodes, a 4 ft. diameter three-stage-rotor prototype unit of the invention's design would achieve a primary voltage expansion ratio equal to about 12,106 given a field emitter $\phi=4.408$ eV and primary cathodes of $\phi=3.639$ eV with both component sets at a temperature of 948° K (or 675° C.) as figured per the above equation. The field voltage expressing this ratio is verified in the Detailed Calculations hereinbelow.

It is important to note that this equation can readily be solved for the required primary cathode ϕ where the projected mean operating temperature of the primary cathodes is given (as it would be in operation), and where the field emitters' ϕ is also fixed and known but their actual operating temperature within a range of possible values must be experimentally or theoretically obtained.

The external breakdown discharge current once initiated and sustained in this manner is generally limited only by the engineered design characteristics of the unit pentode arrays which comprise the Field Induction System. In particular, the negative DC bias voltage applied to the unit pentode array control grids **(65)** must be sufficient to limit the total primary induction ring array current to a value within the safe operating ampacity of the rotor. For purposes of this text, the term "full-power" as used in relation to the Primary Power System and its incorporating device shall be taken to indicate a corresponding rotor speed wherein a full nominal field envelope voltage is achieved, maintained, or exceeded. Such an operational state is depicted in FIGS. **11**, **12**, and **13**.

Field Current Bias

In a simple single-stage rotor embodiment of the Generator used as a "Thermal Power Unit", no active biasing of the current in either of the two current-carrying portions **(140)** of the field envelope (which are otherwise symmetrical) need take place at the primary arrays, and the current comprising each such driving portion of the field is essentially equal. In the preferred three-stage rotor embodiment intended for propulsive units, the field current is actively biased or proportionally shunted by the primary arrays between such field envelope portions **(140)** to render the impulse thrust developed thereby mutually non-isometric along the Generator's vertical centerline. Several important considerations directly related thereto are discussed below, and reference should generally be made to FIG. **7** in this section.

The Generator's maximum full-power total field current must be equal to the rated DC parallel ampacity of the rotor segments, as figured using traditional methods. An operational minimum full-power field current in any propulsive three-stage rotor device used as an "Impulse Drive Unit" should then be considered as equal to either one-half (½) of the so-rated rotor ampacity or a level of total rotor current sufficient to allow the Generator to produce a net vertical thrust equal to its own weight, whichever is the lesser.

Given the minimum engineered amplification factor of the unit pentode arrays **(69)** earlier stated, this minimum full-power field current may in all likelihood be maintained with an average value of primary array negative bias voltage (as applied to the stationary control grids **(65)** shown in FIG. **7**) which is less than or equal to about one-half (½) of its specified design-maximum value. If no unidirectional or alternating voltage component of the Field Induction System current is present, this said average negative bias voltage value constitutes the primary arrays' "zero-signal" bias voltage and the primary arrays may be said to be in a zero-signal field bias condition (as mentioned earlier hereinabove).

Each of the two said driving portions **(140)** of the Generator's field envelope may be referred to as a "field hemitorus" because of its postulated shape, and the maximum individual field hemitorus current at any given value of operating rotor current should at all times be limited to a level which is less than or equal to two-thirds (⅔) of that operating rotor current. Peak net field thrust will then equal one-third the total isometric thrust. Assuming the said given amplification factor, this maximum advisable hemitorus level of proportional total field current may in all likelihood be maintained with an average value of negative bias voltage applied to the corresponding primary array's control grids **(65)** which is equal to approximately one-third (⅓) of its specified design-maximum value (or less proportionally at a rotor current level which is less than rated ampacity).

Due to the lag time in heating either of the two power resistor **(63)** networks through which an increasing field hemitorus current must return, the negative bias voltage applied to the corresponding primary array's control grids **(65)** may be briefly reduced to as little as one-sixth (⅙) of its specified design-maximum value (as a standard minimum operating control grid voltage) or less proportionally at a rotor current level which is less than rated ampacity.

The minimum individual field hemitorus current at any given value of operating rotor current should at all times be maintained at a level equal to or greater than one-third (⅓) of that operating rotor current. Assuming the said given amplification factor, this minimum advisable hemitorus level of proportional total field current may in all likelihood be maintained with an average value of negative bias voltage applied to the corresponding primary array's control grids **(65)** which is equal to approximately two-thirds (⅔) of its specified design-maximum value (or less proportionally at a rotor current level which is less than rated ampacity).

Due to the lag time in cooling either of the two power resistor **(63)** networks through which a decreasing field hemitorus current must return, the negative bias voltage applied to the corresponding primary array's control grids **(65)** may be briefly increased to as much as five-sixths (⅚) of its specified design-maximum value (as a standard maximum operating control grid voltage) or less proportionally at a rotor current level which is less than rated ampacity.

It is important to note that the current passed by the unit pentode arrays **(69)** will depend to a great degree on the accelerator grid **(66)** voltage rather than on the overall primary array potential difference, just as in any standard vacuum tube which employs a screen or accelerator grid whose positive voltage is less than the applied plate voltage. It therefore becomes evident that this positive grid **(66)** voltage may also be modulated in a manner similar to the negative control grid **(65)** voltage. This type of 'duplex' signal-handling or control voltage response capability allows the unit pentode arrays (of either primary induction ring array) to amplify a resonant frequency communications signal while simultaneously controlling an independent level of current-contingent thrust.

In any event, it can be seen here in light of the Law of Conservation of Momentum that a sizeable force of thrust will be developed by each field hemitorus **(140)** from the relativistic impulse of its constituent electrons incident upon the collector housing sections **(5)**, and that suitable means have been provided for rendering such mutually-opposed y-axis thrust vectors variably non-isometric.

A less obvious but very important distinction which should be made in regard to the EDF Generator's production of such electrically-developed thrust is certainly this: it is not necessary that the Generator or in particular its positive hull sections (**5**) (or Field Hub) provide the work required to move the field current charge against the field potential gradient. Per classical electric field theory, the work may be done by the charge itself in being repelled along the potential gradient. In the first case, work is 'performed' and in the second it is 'recovered'. Furthermore, it can be shown mathematically in light of the preceding distinction that any net recoil force experienced by the negative hull Emitter Ring (**47**) is strictly Newtonian in nature, compared to the relativistic impulse thrust produced at the Field Hub, and that the peak value of such recoil would amount to no more than about $^{3}/_{1,000}$ of one percent of the peak net value of the said thrust.

Therefore, the Electrodynamic Field Generator's input rotary torque drive means will provide the work-energy required to establish and maintain the rotor's rotation and the resultant field potential gradient that is induced in the manner described, and the electron charge comprising field hemitorus current will then do the work required to effect its passage toward the positive Field Hub. The resulting collisions are almost completely inelastic, so momentum and kinetic energy are conserved independently, and the field current's gained kinetic energy is recovered almost entirely as heat.

Field Voltage Control System

Accordingly, it can also be seen that the interactive factors or features which result in the EDF Generator's exhibited field voltage as a function of its rotor voltage are much more complicated in nature than the simple turns ratio which defines an AC transformer's secondary voltage in terms of its primary voltage. And because of the extremely high primary voltage expansion ratios which will be operative in large devices, small fluctuations in the Generator's stationary primary array electrode voltages can conceivably cause very large and undesirable fluctuations in the exhibited field voltage. Therefore, a relatively simple but effective Field Voltage Control System is provided which may be used to monitor, regulate, and adjust all individual primary cathode and grid voltages to optimum specified and/or interim operating values such that rotor ampacity is not exceeded, and this system anticipates the use of an associated onboard computer system (to render its various interactive functions automatic).

The embodiment of such a control system as shown in FIG. **10** is intended merely to provide a logical circuit model which is illustrative of the principles of the invention, and of certain principles of appropriate circuit resolution which should be applied within such a system in light of the following aspects of its teaching, and not to preclude the use of other possible embodiments of such control system circuitry.

The cathode elements (**64**) of each plane-parallel electrode system or unit pentode array (used to link the rotor assembly to the positive housing sections) are to have a surface work function ϕ which is significantly lower and/or an operating temperature which is significantly higher than that of the rotor field emitters (**17**), and will therefore tend to exhibit a comparatively much-higher electron emissivity, such that the ratio of their respective temperature emissivity factors (which are each represented by $e^{-\Phi/kT}$) has a very determinate effect upon the respective exhibited ratio of the device's external discharge field voltage to the primary DC voltage generated internally.

Referring to FIG. **10**, these primary array cathodes (**64**) must be composed of tungsten or another refractory metal which may also be either impregnated with thorium oxide or thorium metal submonolayer-adsorbed to achieve such lowered comparative surface work function, and, to calibrate their emissivity relative to that of the rotor field emitters (**17**) as a means of defining and determining the device's external field voltage relative to its primary array potential difference (or half the rotor voltage).

The Field Voltage Control System as shown is basically designed to directly accept the rather high positive induced voltage of the stationary anode rings (**58**) (shown in FIGS. **8** and **9**) for the purpose of providing the primary accelerator grids (**66**) with their standard DC operating voltage. Due to the linear scalability of the Generator's overall design, the nominal (or zero-signal) value of such voltage relative to chassis ground (**10**) is expected to be approximately +362 to +483 volts per foot of hull diameter in three-stage and single-stage Generator embodiments (respectively). An isolation diode (**126**) and switch or relay (**124**) prevent such positive voltage from being neutralized by negative current (s) elsewhere in the control circuit.

Any one or more of the stationary electrode elements (**64**)–(**67**) comprising each said unit pentode array may be artificially cooled, as a means of further regulating the device's external field voltage, and/or subjected to modest variable DC control voltages at times to further assist in the interim adjustment of that unit pentode array's current.

A very high value capacitor (**116**) or a plurality of separate high value capacitors connected into a parallel or series-parallel matrix thereof may be employed to store the displacement charge caused within the Primary Power System by the charging of the rotor-mounted ballast capacitors, as part of such Field Voltage Control System. Said displacement charge holding capacitor(s) (**116**) may hereinafter be referred to as "ballast compensating capacitor(s)".

A very high value capacitor (**117**) or similar such capacitor matrix may also be employed to prevent the grounding of positive housing section potential by ambient ionization charge, from operation in air during the device's start-up period before such sections are fully enclosed (by the external field hemitorus currents), as a further part of this Field Voltage Control System. Such bulk electron storage capacitor(s) (**117**) may hereinafter be referred to as "ambient charge capacitor(s)".

The negative plates of these ambient charge capacitors are to be isolated from ground during rotor spin-up, in order to effect a net negative charge storage, and so their positive plate charge is supplied by a dedicated common variable DC voltage supply (**98**) which is oppositely connected to the ground frame. Each ambient charge capacitor (**117**) employed during the device's start-up period may be selectively switch- or relay-connected by its negative terminal to an accelerator grid element (**66**) of one or more of said plane-parallel electrode systems, in order to effect and control the storage of such ionization charge. Each such start-up capacitor (**117**) may also be selectively switch- or relay-connected by its negative terminal via a variable resistor and/or diode to a suppressor grid element (**67**) of one or more of said plane-parallel electrode systems, in order to effect and control the distribution of onboard stored negative charge reserves from the suppressor grid(s) (**67**) to the rotor, as a standard means of regulating the external field voltage (especially in the vacuum of space).

Said ambient charge capacitor(s) (**117**) may also be similarly connected by the negative terminal(s) thereof either to a separate source of true earth ground or to one or more superconductive current storage ring/s (**200**) (including charge deposition and retrieval means), for purposes of removing any excess ambient electron charge above the bulk storage capability of such capacitor or capacitor matrix which may be produced from normal or full-power operation in air—or other gaseous dielectric media.

Such superconductive current storage ring(s) would be used exclusively in large three-stage rotor propulsive models of the Generator, and thus constitute/s the means by which further expendable onboard charge reserves may be accumulated. The working core of each superconductive storage ring would preferably be a large but relatively thin torus (of small cross section) composed of solid mercury metal immersed in liquid helium, and as such would have a known ampacity measured in the hundreds of thousands of amps.

A linearly-actuated control rod (**103**) or similar mechanism may be used to effect a mechanically variable thermal junction between each primary array cathode or grid element (**64**)–(**67**) and a cold thermal mass of the same or similar refractory metal, maintained at the reservoir temperature of a secondary cryogenic housing coolant such as liquid air or nitrogen. The plate elements and dielectric media of each capacitor or capacitor matrix employed in the Field Voltage Control System could also be incorporated (in a suitable manner) into the coolant vessel which contains said cold thermal mass. This System's diodes would generally not be rated for mounting at such a low temperature.

The voltage control circuit shown in FIG. **10** is modular in nature, in that one such unit is provided for each of the 72 unit pentode arrays associated with the Field Induction System (in the preferred embodiment). All measurements of primary electrode voltage(s), and of positive housing section voltage, are to be made with respect to the Generator's ground frame (**10**) (as generally depicted in FIG. **1**): the metallic structural shell of the device's central chamber to which the rotor carrier assembly drive motor(s) should be mounted. This grounding method is referred to throughout as "chassis ground".

One thermal control rod (**103**) is provided for each primary cathode and grid element (**64**)–(**67**) which variably engages both a control rod socket (**104**) attached thereto and a thermal junction (**101**), which is attached to a cold thermal mass (**102**) maintained at the reservoir temperature of the secondary (cryogenic) housing coolant, by means of a linear actuator (not shown). Such control rod (**103**) may then be used to regulate that electrode's temperature to approximately the same temperature as the associated power resistor (at 675° C. ±55°). In this manner, small adjustments in cathode (**64**) emissivity may be made as necessary during operation and the various grids may be closely matched in temperature to that of their respective cathode(s) to ensure the accuracy of mutual primary electrode voltage balance. Any deviation of cathode (**64**) voltage from a chassis ground potential may be detected and measured across a very-high-value resistor (**107**), connected between said cathode(s) and chassis ground, which is preferably of a large carbon type having multiple fixed taps (and across which an output voltage may exist).

A dedicated common variable DC voltage supply (**95**) is provided for all primary cathodes (**64**) as a means of ensuring an optimum cathode potential with respect to ground, despite fluctuating power resistor temperatures (in three-stage rotor devices where field hemitorus current is variably biased). This supply is shunted with a double-pole/double-throw switch or relay (**123**) to enable either a positive or negative interim control voltage to be applied to the cathodes (**64**), in order to hold their true potential as close to ground as possible. A similar voltage supply (**97**) and switch/relay (**123**) is also provided for all primary accelerator grids (**66**) as a means of modulating the fixed level of applied positive grid voltage (from stationary anode ring (**58**)) and therefore the level of field hemitorus current, independent of the level of applied control grid (**65**) bias. In both cases, these DC supplies are isolated from chassis ground by blocking capacitors (**106**) to inhibit any net charge loss or accumulation from accruing to the ground frame (**10**) during operation (in propulsive units which are not connected to true earth ground).

A dedicated common variable DC voltage supply (**96**) is provided for all primary control grids (**65**) as well. This voltage supply is not capacitor-isolated from chassis ground in this case, so that the primary control grids (**65**) and cathodes (**64**) may have a common direct ground reference as they would in a typical vacuum tube circuit arrangement. The said control grid supply (**96**) should also have a resistor (**107**) of the same type as that provided for the associated cathodes (**64**), connected between such supply's positive terminal and chassis ground. These two criteria further ensure the accuracy of mutual primary electrode voltage balance, and the nominal (or zero-signal) value of such DC control grid voltage relative to chassis ground is expected to be approximately −36 to −48 volts per foot of hull diameter in three-stage and single-stage Generator embodiments (respectively). A variable bypass resistor (**108**) may be adjusted to ensure a very low and relatively constant DC operating grid current despite fluctuations in the value of the AC input signal resistor (**110**), as discussed below.

Ballast compensating capacitors (**116**) are provided whereby negative outrush charge from the stationary anode rings (**58**) and the positive plates of the rotor ballast capacitors may be purged from the Primary Power System during rotor spin-up, to prevent stage electrode array voltage ratings from otherwise being greatly exceeded, via these same two anode rings (one per primary induction ring array), connecting switch/s or relay/s (**124**), and resistor/s (**125**). During the Generator's spin-up and 'run' periods, each ballast discharge switch/relay (**122**) is normally open; switch/relays (**124**) are 'run-open'. Upon rotor de-spin, such ground-restoring charge must be proportionately returned to each stationary anode ring via switch/relays (**124**) and resistors (**125**), and to the Primary Power System as a whole via the discharge switch/relays (**122**) and suppressor grid discharge shunts (with variable resistors (**113**) and diodes (**115**)), for the most part after vacuum chamber current to the hull Emitter Ring has essentially ceased.

Then, such normalizing charge may be 'dumped' across the described suppressor grid discharge shunts at a rate sufficient to ensure that the entire Primary Power System returns to a ground potential (by brief direct surge rotor-shorting to the outer induction array anode rings). Thus, resistors (**113**) provide a variable time constant for the discharging of the said compensating capacitors (**116**). An a independent common variable DC voltage supply (**99**) whose negative terminal is connected to the ground frame (**10**) ensures that the proper total ballast compensating charge described may be stored against the high positive applied potential of the stationary anode rings (**58**).

The ambient charge capacitors (**117**) absorb ionization charge (arising from operation in air) which perforce must fall into the potential well(s) established by the positive housing sections at least until the field envelope's two hemitorus currents are fully formed, and which would otherwise tend to ground the desired positive housing section voltage. Therefore, the negative plate voltage of these storage capacitors (**117**) is applied from another dedicated DC supply (**100**), which is similar to that (**99**) provided for the compensating capacitors (**116**), by means of a common dpdt switch/relay (**119**). None of these DC supplies (**95**)–(**100**) are to have internal load-line diodes.

The variable output of this "dynamic compensating" voltage supply (**100**) is to be approximately the same as that of the ambient charge capacitors' positive voltage supply (**98**), thereby allowing the said capacitors (**117**) to be gradually saturated during rotor spin-up with electrons collected at the accelerator grids via storage shunt inrush current switch/relays (**121**) and diodes (**114**). During the Generator's spin-up and run periods, the "control gate" switch/relays (**119**) are normally closed such that the negative pole of supply (**100**) is connected to the negative plates of these same capacitors. In the Generator's run and de-spin periods, however, switch/relays (**121**) are normally open.

Any excess ionization charge above these capacitors' joint storage capability which might lower the 'run' Field Induction System circuit voltage must then be either grounded off or deposited in said superconductive storage ring(s) (**200**) (in ungrounded propulsive Generators designed for maximum ambient charge storage), via the same said throw of control gate switch/relay (**119**) in conjunction with shunt switch/relay (**120**) and resistor (**112**). In this case, the storage shunt switch/relays (**121**) remain run-closed. Otherwise, the slow 'run' release and distribution of negative charge reserves to the rotor from the storage capacitors (**117**) is effected by the gradual synchronized relaxation of the voltage/s from supplies (**98**) and (**100**) across switch/relay (**119**) and discharge resistor (**113**), with shunt switchs (**120**) and (**121**) open, while diodes (**114**) and (**115**) ensure that the said capacitors (**117**) may only be discharged in the manner described.

This discharge of stored charge reserves actually takes place from the suppressor grids (**67**), which may serve as low-power electron emitters given their proximity to the primary anode rings (**68**). An isolation diode (**127**) prevents such negative charge from neutralizing accelerator grid circuit voltage. It should be noted that the suppressor grids may be held at ground potential as they would in a typical beam power pentode circuit arrangement, or at a very low if not negligible negative voltage for purposes of effecting such controlled low-power charge release, by means of [i] a minor negative voltage induced thereon by the corresponding proximal primary anode ring/s (proportional to their capacitance relative thereto); [ii] the combined DC voltage drop across the paralleled resistors (**109**) and (**111**) connected to their respective accelerator grids; and/or [iii] the voltage of the dynamic compensating supply (**100**) relative either to earth ground and resistor (**112**) or to chassis ground and the relative opposing voltage of the ambient charge storage capacitor's supply (**98**).

The bypass resistor (**109**) provided between each accelerator grid (**66**) and its associated suppressor grid (**67**) returns the inevitable stationary anode ring (**58**) and accelerator grid (**66**) DC circuit current to the rotor from the suppressor grids (**67**), and simply assists in maintaining each suppressor grid at a DC potential as close to true ground as possible. The suppressor grid resistor (**111**) which is paralleled with said bypass resistor (**109**), however, is analogous to a plate resistor on behalf of the corresponding inner (rotor) induction array in both the single- and three-stage rotor embodiments, in that any rotor circuit final-stage AC output voltage variations will be reproduced across it once field envelope circuit current commences. Likewise, any AC signal oscillations from an outside (remote) source which are induced upon the field envelope current will immediately act as a detected first-stage AC input for rotor circuit amplification, and again will be reproduced across the said grid resistor (**111**).

Therefore, any rotor or field circuit AC potential difference across this grid resistor (**111**) provides an output signal voltage that may be: [i] received by an actual communications console or a simple AC control-voltage operating circuit in the Generator's central cabin; and/or [ii] reapplied either in- or out-of-phase with the voltage across the input signal resistor (**110**) of the associated control grid (**65**) as a further AC signal voltage amplification or suppression stage (respectively). An input AC signal or control voltage may also be applied across the control grid resistor (**110**) from such an onboard communications console or control-voltage operating circuit, as would generally apply to three-stage and single-stage devices, respectively. This grid resistor is variable for circuit tuning purposes related to resonant frequency communications (if desired).

It can be seen from FIGS. **8** and **9**, however, that the AC output amplification stage (or inner induction array) of the Primary Power System and its input stage (or outer induction array) are directly coupled by the rotor segments (**14**) in both single-stage and multi-stage rotor embodiments. Thus, the rotor electrical circuit as configured will be subject to continuous positive (or regenerative) feedback of any AC signal voltage present either in the field current or on the rotor, as described above. To provide a desired or requisite level of signal amplitude suppression or compensation, negative (or inverse) feedback may be applied to the rotor circuit using the feedback coupling relays (**129**) and stage transformers (**130**) shown in FIG. **10**.

Because plate voltage and grid voltage are typically 180° out of phase in a beam pentode arrangement such as the Generator's primary arrays, inverse feedback is achieved when the voltage fed back to the control grid (**65**) has the same waveform and phase as the plate or anode (**68**) voltage. In related traditional practice, an inverse feedback signal applied to the input (control grid) current decreases AC amplifier input impedance and distortion; an inverse feedback signal proportional to the output (plate/anode) current raises the output impedance of such amplifier. Therefore, an inverse feedback AC signal proportional to the current through resistor (**111**) which is applied in-phase with the AC line current across resistor (**110**) decreases the rotor input stage impedance yet also reduces the amplitude of the AC output current. A loss of total amplification (through a fractional stage 'gain') results, but is accompanied by a decrease in signal distortion.

The stage feedback transformers (**130**) ensure voltage reference isolation between such stationary amplification or suppression stage and the corresponding rotor stages, when AC signal feedback across the control grid resistors (**110**) is necessary or desired. A double-pole/double-throw switch/relay (**129**) may be used to decouple each such transformer from the input signal resistor (**110**) side of its circuit connections, and/or to apply either positive (regenerative) or negative (inverse) feedback to the rotor AC amplification stage(s), and tunable blocking capacitors (**131**) isolate the transformers from circuit DC voltages. The coupling transformers (**130**), isolation relays (**129**), and blocking capacitors (**131**) are therefore only necessary in Generator embodiments not having a central AC control-voltage operating circuit with suitable inverse feedback characteristics and in three-stage Generator embodiments which may be used in a communications capacity. In the latter case, an optional capacitor across the secondary or control grid resistor (**110**) side of each such transformer (in parallel with the said resistor) may once again be employed in parallel resonance fashion, and is indicated in FIG. **10**.

During continuous operation of an EDF Generator in the vacuum of space, the exhibited DC field voltage will tend to rise gradually as the total amount of charge contained in the field envelope circuit is gradually reduced through unavoidable electron leakage losses (primarily at the hull Emitter Ring peripheral edge). To compensate for this effect, a small amount of stored ambient charge must therefore be continually released at the suppressor grids (**67**) into the rotor return current. The rate at which this gradual discharge must be effected is dependent upon the observed field leakage rate, as only a rough approximation of this leakage may be pre-calculated. It is for this reason that at least one superconductive storage ring (**200**)—containing a tremendous quantity of reserve ambient charge in the form of a continuous zero-loss current—must be included in any ungrounded Impulse Drive unit used in space exploration, as the capacity of such storage ring determines the vessel's effective range of operation.

It is postulated that the external field current's energy density will be sufficiently enormous that it exhibits a virtual self-evacuating operational condition above a certain ultrahigh field voltage in propulsive three-stage EDF Generators, and such a condition is essential to the successful atmospheric ground launch thereof Such kinetic occlusion of a significant portion of the otherwise available ambient ionization charge may also occur once the field envelope is fully formed even in ground-based single-stage devices operated at breakdown field intensity. During continuous operation of such ground-based devices in a gaseous atmosphere, field leakage losses which could cause an undesired gradual field voltage rise if they exceed available ambient charge accretion may be compensated by bypass-shunted charge from earth ground. In this case, the positive pole of supply (**100**) is connected at low power via dpdt switch/relays (**119**) to earth ground, in order to avoid a limited spin-up/run/de-spin repeating duty cycle.

General Method of Construction

The actual construction of an Electrodynamic Field Generator of any given size is relatively straightforward, whether of a manned propulsive embodiment or not, and proceeds in fact from the inside out. Referring generally to FIG. **1**, one of the most practical features of the construction process is that virtually the entire instrumentation and payload compartment or "Central Chamber" (**2**) may be outfitted first, before any portion of the Primary Power System is assembled or even necessarily designed. In the preferred three-stage embodiment to be used as an aerospace Impulse Drive Unit, the central chamber should obviously incorporate low-density materials wherever possible.

Construction next proceeds with the Generator's ground frame (**10**): the metallic structural shell which provides an enclosing framework for the central chamber to which all ancillary inboard electrical equipment may be grounded. This structural framework should be as strong, lightweight, and nonmagnetic as possible, and may preferably be of a welded tubular design using stainless steel or a suitable titanium alloy.

Once the ground frame and enclosed central chamber are completed, including the installation of a preferred total of 32 high-torque DC motor-generator rotor drive units (in four sets of eight), the two rotor mounting frame sections and attached ring gear/s (**8**) of the "Carrier Assembly" may be built and dynamically balanced (using a temporary peripheral spacing "jig"). Then, construction of the composite "Rotor Assembly" may commence with the laying out of equal numbers of copper segments (**14**), ceramic segment separators (**16**), and refractory composite field emitters (**17**) which are all of exactly equal weight by type, the latter components providing the nonconductive base to which other rotating electrical hardware may be attached.

When the three sets of said principal large rotor pieces (which preferably number 180 each) are bound together with electrode rings silver-soldered to the segments, and clamped between the two halves of the centrifuge-style carrier assembly, the assembly of the "Primary Power System" itself may begin. Once thin insulative rotor surface "facing", the aforementioned recessed and conductive separator traces, and the rotor ballraces (**25**) have all been affixed to the base rotor assembly, and the field coils, electrode arrays, and other rotating components have been added, the fabrication of the vessel's "Structural Intercooler System" may proceed. When this secondary thermal conduit (hull coolant) system is completed and has been pressure-tested, the "Primary and Magnetic Arrays" may be installed—including the 5-armature variable inductor array sections depicted in FIG. **14**. The primary (induction ring) arrays here are comprised of the unit pentode arrays (**69**) as individual assemblies each having an adjunct assembly comprising a field power resistor (**63**), dielectric buffer (**45**), and primary thermal conduit (**48**).

Finally, once the rotor has satisfied nonenergized operational mechanical clearance and dynamic balancing criteria (using a temporary outer rotor bearing support "jig") and a final complete thermal conduit system pressure test has been made, the "Outer Hull Components" may be installed. Thus, the basic vessel construction may be completed in a total of seven distinct steps or stages. Due to the tremendous weight of the finished rotor (as the device's most massive single assembly), an operating characteristic of utmost importance is the actual rotor speed required to maintain a specification field voltage which is figured using the method outlined in the Detailed Calculations below. This will determine the rotor's operating angular momentum, which in propulsive units must be sufficiently large to provide gyroscopic stability against the use of variably-imbalanced isometric thrust (produced by field hemitorus current) but not so large that the vessel's navigational and maneuvering characteristics are thereby rendered sluggish.

It can be shown mathematically that the nominal rotor speed for a 4 ft. diameter theoretical design prototype would be roughly equal to or somewhat less than that of a typical small electric motor. However, as the size of the device increases, it will be necessary to reduce rotor rpm due to the extreme increase in the rotor's 'tip' speed and therefore the centrifugal forces to which it is subjected. Sufficient information is contained in the basic specifications which underlie this disclosure to allow engineers to reduce rotor speed as necessary in larger devices following the course of an intensive program of small device tesing; e.g., the projected nominal rotor rpm for a 20 ft. Thermal Unit is 1045.

Structural Intercooler System

The secondary thermal conduit sections which carry hull coolant or heat transfer fluid through the Generator's tapered "Drive Ring" (or the combined volume of the negative and neutral housing sections) must pass between the power resistor and unit pentode array assemblies, and so they must conform in outside dimension to the available space within the supporting framework of the neutral hull construction. The most unusual feature of these secondary conduits is that they also comprise (of necessity) the principle Drive Ring load-bearing members, and together they form the EDF Generator's structural intercooler system as illustrated in FIG. **14**.

These secondary hull coolant conduits should be fashioned in a manner similar to the primary thermal conduits described hereinabove, and in the preferred embodiment would be formed in four types or varieties: [i] the initial outbound coolant supply runs **(75)**, called "headers"; [ii] the circumferential heat transfer sections **(76)** (to which the Emitter Ring hull plates are fastened), called "peripheral shunts"; [iii] the inner **(77)** and outer **(78)** intermediary coolant runs, or "transfer links"; and [iv] the radial coolant returns **(79)** or "recovery lines". Within the Drive Ring, each of these conduit types may be fashioned as single sections which connect one to another in 'series-parallel' branch systems or zones. To wit, one header **(75)** from a reservoir coolant manifold **(74)** connects to one peripheral shunt **(76)** which in turn connects to one recovery line **(79)**.

Thus, a single coolant zone is illustrated in FIG. **14**, the arrows indicating the direction of coolant flow. A molded ceramic support bracket **(71)** having integral elbows and a set of mounting "knuckles" may be used to secure the inner corners of each two adjacent negative hull plates **(72)**, by means of a matching mounting ring welded to each inner plate corner and a retaining pin (not shown). Each Emitter Ring hull plate **(72)** is to have an angle-stock thermal transfer channel welded along but just inside its inner edge (as indicated by dashed lines), which encloses the corresponding peripheral shunt **(76)**.

These coolant headers, shunts, transfer links, and recovery lines are preferably formed of molybdenum tubing, and would take advantage of the high thermal conductivity and electrical resistance of a thin Alumina coating thereon to absorb excess heat from the single-stage Drive Ring hull and (in particular) the Emitter Ring hull plates. In single-stage rotor devices which are used as Thermal Power Units, the recovery lines then exit the Generator housing through two exchange manifolds (as stated earlier), from a preferred total of 72 individual coolant zones, to an external heat exchanger. Just how effective this method of cooling the Drive Ring as a whole will prove to be during operation in air, using the preferred liquid air or nitrogen coolant, is somewhat difficult to project. Liquid helium could alternatively be used in this respect to ensure adequate hull cooling, but would entail significantly increased piping and pumping difficulties in doing so.

It is expected, however, that the intercooler system described will be satisfactorily effective during the operation of three-stage devices in the vacuum of space, and is principally designed with this mode of usage in mind. Accordingly, it is believed that an Impulse Drive Unit operated in space will be able to purge its excess heat by actually circulating the primary conduit liquid sodium or equivalent through the secondary thermal conduit system (instead of the cryogenic coolant). In this case, the intercooler structure is used to transfer heat to the Emitter Ring hull plates as a radiative heat sink. This cooling method would provide the necessary means of liberating the Generator from permanent ground-based support to achieve free-ranging operation in space.

Neutral Housing Section Construction

In order to establish and withstand the action of the field envelope discharge current, the surface of the neutral sections of the Generator's housing or hull (or "Neutral Ring") must be constructed entirely of specialized nonconductive material(s) which should be applied in two layers to an underlying superstructure that is actually conductive in nature. It is proposed that overlapping ceramic 'tiles' be used in this regard, in a manner rather like that employed on the NASA space shuttles, which are adhesed to an underlying deck of structural nonmetallic sheet stock While the intercooler system conduits (described in the preceding section) comprise the principal load-bearing members which support the Drive Ring portion of the hull, a system of beams **(153)** and struts **(152)** that are also composed of the same nonmetallic structural material as the deck or a similar and compatible material should be utilized to further strengthen and 'unitize' the Drive Ring superstructure such that an internal hard vacuum may be drawn and maintained prior to operation. These secondary load-bearing members are also depicted in FIG. **14**, and in a preferred embodiment these members and the base deck material itself would be composed of a carbon composite commonly referred to incorrectly as graphite.

Sophisticated carbon composites similar to those found in golf-club shafts and racing-bicycle frames were first developed to make use of their special combination of extreme strength, rigidity, and lightness in aerospace applications. These materials are generally made from polyacrylonitrile (PAN) carbon fibers which are heated under tension to drive off the non-carbon portion. The individual fibers are about 7 microns in diameter and approach 300 kpsi in tensile strength. They may then be pulled into a rope-like 'tow' or woven into a fabric-like 'matte' before being coated with either epoxy or polyester resin. Therefore, carbon composites are eminently suited to forming rods, tubes, and sheets, and display excellent vibration damping characteristics. The final product is, however, still very expensive per pound.

To simplify the vast diversity in specialized grades of PAN carbon composite for purposes of this application, this material should be considered as coming in two basic density grades: low-density "deck" grade (at about 35% of the specific gravity of sheet steel), and high-density "beam" grade (at about 65% of the specific gravity of structural steel). It is also available in two standard temperature grades, depending on the bonding agent used: a 350° F. rating (lo-temp) epoxy-bonded material and a 750° F. rating (hi-temp) polyamide-bonded composition. The hi-temp grade only should be employed in the Neutral Ring, but the lo-temp grade may be used to build the Central Chamber.

Thus, a low-density/hi-temp grade of carbon composite laminate should be used as the basic deck material in construction of the Neutral Ring hull sections. To wit, this deck layer itself is initially affixed to the vessel superstructure by solvent welding and/or mechanical means. The PAN carbon deck, a middle layer of ceramic substrate plates and an outer skin of exolayer tiles together then comprise the composite Neutral Ring hull. Several factors enter into the selection of an appropriate ceramic material for the substrate layer plates. Of primary concern here is that the material of choice have a very high volume resistivity and very low thermal conductivity at temperatures from 300–500° C. It is also important that the material have a very low thermal expansion coefficient, as the substrate layer plates must be bonded to the deck layer with a refractory-class adhesive. Therefore, the substrate material should also be non-vitreous and have relatively high porosity to promote adequate adhesion. One of the Cordierite class of compounds, bearing CeramTec designation 447, has relatively low hardness and flexural strength but should function admirably in Thermal

Power Units as the center layer of a bonded composite construction given its other highly desirable characteristics. Impulse Drive Units will require an alternate substrate plate material as discussed below.

The selection of a ceramic material for use as the exolayer dielectric thermal tiles of the EDF Generator's housing or hull is contingent upon the operative field voltage, and therefore different materials must be specified for Thermal and Impulse Drive Units. To prevent substantial skin conduction losses, the minimum dielectric value k for the exolayer tile material used in Thermal Power Units has been calculated (using the peak field voltage) at approximately k=9. Therefore, the material of choice is a Zirconia composition bearing CeramTec designation 848, with a minimum (high-frequency) dielectric constant of 28. Even though this material has a comparatively high thermal expansion coefficient, it has very low thermal conductivity and is very dense and hard. Moreover, it exhibits exceptional flexural strength and resistance to fracture.

The minimum dielectric value k for the exolayer tile material used in Impulse Drive Units has been calculated at approximately k=107. Therefore, the material of choice is the same titanate composition prescribed for the dielectric buffers (and described in some detail in a previous section). Known chemically as Sodium Bismuth Titanate (and commercially as Kézite), this highly unusual compound is technically a piezoelectric material, but is also ferroelectric in that its dielectric constant actually increases on temperature rise to a peak low frequency value of about 3,100 at its 655° C. curie point. Like most ferroelectrics, its tensile and flexural strengths are quite low yet it is very dense and exceedingly hard. It does, however, exhibit a thermal expansion coefficient which is very high for a ceramic material.

The expected higher flexural stresses upon the Neutral Ring of an Impulse Drive Unit (compared to a Thermal Power Unit) may prove sufficient to crack the substrate plates were they composed of the Cordierite material described above. The Zirconia compound mentioned earlier should therefore be substituted for Cordierite 447 as the substrate plate material in Impulse Drive Units. This would likely stiffen the composite Neutral Ring hull adequately to prevent such stress cracking, while effecting a much closer match in thermal expansion coefficient to the titanate tiles. In both Thermal and Drive Units, the exolayer tiles should be applied to the substrate plates with a refractory-class adhesive in a mosaic overlay pattern, such that the edges of each exolayer tile are evenly spaced as far as possible from the underlying edges of the nearest substrate plates.

Because the underlying deck layer of the Neutral Ring hull will be quite conductive when composed of carbon composite sheeting, and referring now to FIG. **1**, it becomes imperative to use an auxiliary dielectric buffer **(50)** between the inner edges of the Emitter Ring **(47)** hull plates and the outer edge of the said deck layer to prevent an otherwise enormous deck leakage current from occuring. Although it might seem that the much-cheaper and nearly-as-strong fiberglass composites available (which are nonconductive) would tend to minimize any such leakage current condition, their use would not prevent the possible build-up of unacceptable levels of static charge within the working induction compartment **(12)**. Therefore, the use of conductive deck material ensures that the Faraday shielding principle protects Neutral Ring components from transient static voltages because the presence of a finite deck leakage current means the deck layer is a charged conductor, whereupon any net static charge must be external.

A secondary concern is the actual operating temperature of the contact areas where the deck layer abuts to both the auxiliary **(50)** and primary **(45)** dielectric buffers, which must be kept below the 750° F. temperature rating of the carbon composite. It can be shown mathematically that the deck leakage current can be held to a thoroughly acceptable fractional amperage per cm^2 of such contact area if this condition is met. In Thermal Power Units, the use of a secondary cryogenic hull coolant should keep the auxiliary buffers **(50)** and outer deck contact areas at a temperature which is under the said rating. Doing so at the primary buffer **(45)** contact area locations may well require the use of auxiliary cryogenic thermal conduits in both Thermal and Drive Unit models of the EDF Generator. The auxiliary dielectric buffers in any given Generator should be composed of the same material used in that device's exolayer tiles, and should be of about half the radial thickness of the primary buffers employed therein.

While the specific materials discussed above should not be construed as critical to the EDF Generator's proper construction, their properties and characteristics are highly indicative of the rather involved considerations which must be undertaken to ensure that the neutral sections of the vessel hull are physically suited to optimizing a given size device's performance and minimizing its housing maintainance or repair requirements.

Stationary Electromagnetic Armatures

Because the EDF Generator's stationary electromagnetic armatures have no bearing on the device's rotor or field voltages, and no direct connection therewith, they are properly thought of as being part of neither the Primary Power System or Field Induction System circuits but rather a separate ancillary subsystem intended to optimize the invention's overall performance and efficiency in a number of important ways. To this end, their main purpose is to create and independently control a variable level of both rotor torque and field current rotational force, as necessary or desired.

As depicted in FIG. **14**, the individual stationary armatures **(37)** (or "variable inductors") may be installed in 5-armature groups or array sections within the Neutral Ring of the hull, using notched and mating supports **(151)** which firmly clamp the armatures about a reduced diameter center section of each armature core. These armatures and a basic control circuit arrangement for them are shown in FIG. **16**, with the polarities indicated being those which would result in a clockwise rotation of the rotor as viewed from above. This armature power distribution system may be manually adjusted and/or automatically controlled (using a computer and/or other circuitry).

In both single-stage and three-stage embodiments of the Generator, each of the two electromagnetic armature arrays should be wired in parallel from one or more separate source(s) **(185)** of low-voltage DC current which is/are chassis-grounded and which is/are common to the armatures **(37)** of that array. No variable regulation or biasing of individual armature DC current(s) in single-stage rotor or Thermal Power Unit devices is necessary. The desired individual biasing of armature DC current in three-stage rotor devices, for propulsion-related reasons explained below, may be simply accomplished through a variable resistor **(184)** associated with each armature and its DC power supply subcircuit(s). A minor unidirectional or alternating voltage component of such armature supply current may be added across or in parallel with such resistor **(184)**, using an AC power source **(186)** and/or suitable control interface of a conventional nature, in either single-stage or three-stage Generator embodiments as desired.

Each stationary armature **(37)** incorporates two separate electrical coils **(180)**–**(181)**, to be operated principally on DC voltage, which are formed of conductive insulated magnet wire multi-layer wound upon a single ferromagnetic core. Each such armature core also incorporates a connecting center section or "flux reductor" **(182)** between said separate coils which is of a significantly reduced cross-sectional area with respect to the balance thereof, and which is designed to saturate magnetically when the respective core flux density of either of said coils is approximately equal to or greater than half saturation value. Pure annealed iron or low-carbon steel should be used as the armature core material, due to the high permeability, superior intrinsic induction, and low hysteresis thereof.

The inner or "flux initiator" coils **(181)** of these electromagnetic armatures (or those closest to the rotor) may be used as a means of creating axial magnetic fields of force **(144)** which are perpendicular to the plane of the current-carrying rotor segments **(14)**. Thus, when powered collectively at a common DC current value, the said inner armature coils **(181)** in conjunction with their respective cores may serve as a source of uniform yet variable secondary input rotary torque (or in a torque-assist capacity) for the invention in the course of its normal operation as an electrical generator.

The flux initiator coils **(181)** are so-named because their as-wound polarity relative to the fixed outward direction of the primary DC rotor current establishes both the direction of rotor rotation and the required winding direction and polarity of the outer (and similar) armature coils **(180)**. The said inner coils **(181)** are energized by a variable DC power supply **(185)**, through an output variable resistor **(184)** and a filter diode **(189)** which blocks induced positive AC half-cycles (if any) from crossing the negatively-grounded DC supply **(185)**. Such power supply **(185)** must, however, be sufficiently rated to carry any corresponding induced unidirectional negative current impulses to ground, and may be of a solid-state or rotary induction design.

The axial armature-produced fields **(144)** described may also be individually and variably superimposed on the rotor to develop a selectively controllable force of rotational torque upon its current-carrying segments **(14)**, through variable regulation of the principal DC current in individual armature inner coils **(181)**, such that a locally-unbalanced force of angular acceleration may be applied to the rotor and therefore a directional force of horizontal thrust may indirectly be imparted to the housing for lateral flight maneuvering in propulsive three-stage rotor devices.

The outer coils **(180)** of the stationary electromagnetic armatures, or those closest to the field envelope, may be used as a means of creating axial magnetic fields of force **(144)** which in this case are essentially perpendicular to the described field current arc trajectories. This situation is best illustrated in FIG. **12**, which shows the hull location of the two variable inductor arrays **(145)** (or circular groups of armatures **(37)**). Thus, when powered collectively at a common DC current value (including any minor unidirectional or alternating component thereof), these outer armature coils **(180)** in conjunction with their respective ferromagnetic cores serve to impart an attenuating yet holistic and orderly rotational vector moment upon the external discharge current. The general effect of such applied magnetic rotational force, which may be used to modify or modulate the field's electrodynamic characteristics, is further depicted in FIG. **13**.

Referring again to FIG. **16**, and to continue in the same vein, it is postulated that the quasi-coherent aspects of the field envelope may actually be optimized through the proper control of the amplitude, frequency, and/or phase relationships between any minor AC voltage component of the field envelope current and the said minor AC current (if any) collectively supplied by AC power source **(186)** to the outer or "transflection" coils **(180)** (of each variable inductor array). This consideration applies to both single- and three-stage embodiments of the Generator, although it is decidedly more important in the case of the latter, and may also allow the engineered reduction of field radiative emissions.

These transflection coils **(180)** are so-named because they may be used to impart a variable transverse deflectionary force upon all of the radially-impinging field current electrons. In the region(s) of the field envelope shown in FIG. **11** between the surface of each neutral hull section **(4)** and the corresponding field envelope inner boundary **(142)**, this magnetic force may in fact be large enough to produce a continuous annular flow of "displacement charge" current. In any event, and as shown in FIG. **16**, such outer armature coils **(180)** are also energized by a variable DC power supply **(185)** which is similar in type to that of the inner coils **(181)**, through an output variable resistor **(184)** and filter diode **(189)**. In addition, a variable AC power source **(186)** may impress a minor unidirectional or AC voltage upon the DC current supplied to the said transflection coils **(180)**, either across or in parallel with the output resistor(s) **(184)** of their respective DC power supply subcircuit(s), through separate output variable resistors **(184)** and DC blocking capacitors **(188)** connected to said AC power source.

The axial magnetic fields **(144)** produced by the armatures **(37)** may also be individually and variably superimposed on the field envelope to develop a selectively controllable rotational force upon the described field hemitorus current, through variable regulation of the principal DC current in individual outer (or transflection) coils **(180)**, such that a locally-unbalanced force of angular acceleration may be applied to such hemitorus current. Any such angular force imbalance will cause a corresponding change in the local field current density and therefore a secondary directional force of variable thrust in the z-axis may indirectly be imparted to the housing in propulsive devices, yielding a further measure of navigational attitude control over non-isometric thrust produced by the Generator which may otherwise be largely unilinear.

Given the nature of the flux reductor **(182)** as described above, it can be seen that either the inner or the outer armature core sections may be collectively or individually operated at any flux density above half of saturation level without significantly affecting the operating flux density of the respective opposite core sections, provided both corresponding sets of armature coils (**(181)** and **(180)** respectively) are powered by DC current of the same relative polarity. Thus, the base collective full-power operational level of flux density in the inner armature core sections of a three-stage rotor Impulse Drive Generator should be roughly half saturation level, in order to facilitate the achievement of temporary local rotor torque imbalances for propulsive purposes as described above. Such inner core section base flux density for single-stage rotor or Thermal Power Unit devices may be any desired in a range between 0 and 100% of saturation.

As shown in FIG. **16**, means have nevertheless been provided for reversing the fundamental DC polarity of either the inner **(181)** or outer **(180)** coil of any given armature **(37)**, without changing the given polarity of such coil's DC power supply **(185)**, using a dpdt relay **(190)**. It can be seen that this simple feature allows a counter-polarity magnetomotive force (or counter-mmf) to be applied to either wound core section of any given armature, with respect to the core polarity of that armature's opposite wound section. This feature, when taken in conjunction with the described nature of the flux reductor(s), enables the outer armature core sections in both single- and three-stage devices to be operated at nearly any flux density within their output capability which might be required to optimize the desired quasi-coherent properties of the field envelope, despite the relative polarity and/or flux density of the inner armature core sections. In both single- and three-stage devices, these same two features also allow a substantial level of braking or counter-rotational torque to be applied to the Generator's rotor —by any or all of the inner armature core sections— while maintaining such an optimum level of flux density in the outer armature core sections: even if the two such opposite core sections are operated at opposite respective polarities.

Detailed Calculations for Preferred Embodiment

It is important to note that all of the underlying specifications pertaining to the size and/or positioning of Primary Power System components located within the hull's neutral section region (or "Neutral Ring") are given in terms of fractional increments of the hull radius (R_h) and/or the radial width of the Neutral Ring (C_v–C_a). This means that these components may be easily scaled in exact proportion to the hull, for any selected radius thereof, with no significant error or modification. However, an upper limit of vessel size utilizing the technology represented by the EDF Generator probably exists at a hull diameter not greatly above 100 feet, due to inordinate DC Field Voltage concerns (as that voltage is calculated using the method below).

Table of Dimensions	
Hull Radius = R_h	
Hull Volume Constant (C_v)	$C_v = \frac{1}{5}R_h$
Hull Area Constant (C_a)	$C_a = 0.012919C_v$
Drive Ring Radius (r_f)	$r_f = 2C_v$
Emitter Ring Radius (r_{neg})	$r_{neg} = C_v + C_a$
Neutral Ring Radius (r_{neut})	$r_{neut} = C_v - C_a$
Field Hub Radius (r_z)	$r_z = 3C_v$ (Note: $R_h = r_f + r_z$)
Polar Hull Constant (h_z)	$h_z = 0.1421245r_z$
Polar Volume Differential (X_h)	$X_h = \frac{(r_z^2 - h_z^2)}{2h_z}$
Radial Hull Constant (R_s)	$R_s = h_Z + X_h$
Area of Positive Zone (A_z)	$A_z = 2\pi R_s h_z$
Area of Negative Section (A_n)	$A_n = \frac{s(C + c)}{2}$, where: $s = \sqrt{(C_v + C_a)^2 + (\tan\alpha(C_v + C_a))^2}$, $C = 2\pi R_h$, and $c = 2\pi(R_h - (C_v + C_a))$, and Note: $A_z = A_n$.
Volume of Central Section (V_c)	$V_c = \pi r_z^2 h_f$, where $h_f = r_f(\tan\alpha)$, and α is the said Emitter Ring angle.
Volume of Positive Zone (V_z)	$V_z = \frac{2}{3}\pi R_s^3 - \pi\frac{R_s^2 X_h - X_h^3}{3}$
Vol. of Drive Ring Section (V_f)	$V_f = \frac{\pi h_f(R_h^2 + R_h r_z + r_z^2)}{3} - \pi r_z^2 h_f$ Note: $V_z = V_f$
Total Hull Volume (V_t)	$V_t = 2(V_z + V_f) + 2V_c$

The variable 'α' equals the displacement angle of the Emitter Ring negative sections (with respect to the hull's horizontal centerline plane), which is preferably 7.5° to 8° each.

Field and Rotor Voltages

Part A: Model Unit Field Intensity

[1] The Marginal Envelope DC Field Intensity for all EDF Generator models regardless of type should be equal to the breakdown dielectric strength of air or vacuum at 3 million (3×10^6) volts/meter, as measured along a full pure semicircular arc drawn from the center point on the surface of either hull Positive Zone (**5**) to any exterior point on the vessel's design hull configuration which lies on the horizontal centerline plane thereof. This distance shall be referred to as the "Drive Field Perimeter" (**141**), as shown in FIG. **11**, and is taken to represent the longest continuous DC field current trajectory.

[2] For purposes of these Specifications, the "Drive Field Boundary" (**142**) shall represent the distance measured along a full pure semicircular arc from any point on the outer peripheral edge of either hull Positive Zone (**5**) to the closest point thereto which lies on the inner peripheral edge of the vessel's corresponding negative hull section (**3**) (as shown in FIG. **11**), and is taken to represent a shortest such DC drive current trajectory.

Part B: Thermal Power Units

[1] The Nominal Field Voltage (nom.V_f) should be numerically equal to 1.5 million (1.5×10^6) times the vessel R_h as measured in feet. This value is also equal to the Thermal Unit's standard design Primary Voltage Expansion Ratio of 750 times its Specification DC Primary Array Voltage, as a function of the charge stored within the Primary Power System's two Field Ballast Capacitors and of the Unit's primary cathode emissivity.

[2] The Specification Field Voltage (spec.V_f) should be equal to the Marginal Envelope DC Field Intensity times the distance comprising the Drive Field Perimeter, or (as presently calculated under the above directive) 0.9666 times the Nominal Field Voltage. This value shall constitute the Unit's standard operating value of field envelope voltage.

[3] The Peak (design operating maximum) Field Voltage (max.V_f) shall be equal to 110% of the Specification value thereof, and should never be exceeded in operation.

[4] The Nominal Rotor Voltage (nom.V_r) would be numerically equal to one-third the product of 1,000 (1×10^3) times the vessel R_h, as measured in inches, as a gauge of the basic full-power DC generator value of rotor rotational speed, in a 'single-stage' device.

[5] The Specification Rotor Voltage (spec.V_r) should be numerically equal to 0.25776% of 1.5 million (1.5×10^6) times the vessel R_h as measured in feet, and is also equal to 0.9666 times the Nominal Rotor Voltage. This value would constitute the standard operating value of DC rotor voltage, as a function of the engineered Primary Power System output at a nominal design rotor rotational speed.

[6] The Peak (design operating maximum) Rotor Voltage (max.V_r) shall be equal to 110% of the Specification value thereof, and should likewise never be exceeded.

[7] The Specification DC Primary Array Voltage (spec.ΔV_p) will be equal to half (½) of the Specification Rotor Voltage, and affects all primary array electrode spacings.

Part C; Impulse Drive Units

Unlike the case with Thermal Power Units, it is not possible to specify in one step a Nominal Field Voltage for Impulse Drive Units which is a linear function of the hull radius R_h; the DC Field Voltage which must be produced to achieve the chosen design goal for net linear thrust output, equal to five-thirds the Earth's pull of gravity, is jointly proportional to the rotor ampacity which rises as a function of the square of increases in R_h and to the vessel weight (which rises as a function of the cube of R_h increases).

Therefore, a Marginal Field Voltage is initially to be computed for Impulse Drive Units which reflects a projected theoretical operating value of DC Field Voltage required to produce a vessel acceleration approximately equal to 1.67 'g' outside of a proximal gravity field. This Marginal Field Voltage is to be calculated using the "specific impulse" of the vessel concerned (in nt-sec), and for purposes of the application contemplated herein this term is hereby defined as being equal to five times the vessel weight (in newtons) divided by the rotor ampacity times the number of electrons per coulomb.

[1] Accordingly, the Marginal Field Voltage shall then be equal to the Unit's specific impulse (F_{dt}) times the speed of light (c) divided by the unit electron charge (q).

[2] An estimated nominal Field Voltage will also be computed whereby a nominal value for the final electron speed of Drive Field current is assigned which is in fact a linear function of R_h, as applicable to vessels of from 4 to 100 ft. in diameter only.

[3] The Nominal DC Field Voltage (nom.V_f) should then be equal to the simple average of the Marginal Field Voltage and the said estimated nominal Field Voltage.

[4] The Specification Field Voltage (spec.V_f) should equal the Nominal DC Field Voltage (nom.V_f) divided by an assigned engineering design constant equal to 0.982826.

[5] The Peak (design operating maximum) Field Voltage (max.V_f) shall be equal to 110% of the Specification value thereof, and should never be exceeded in operation.

[6] The Nominal Rotor Voltage (nom.V_r) would be numerically equal to one-fourth the product of 1,000 (1×10^3) times the vessel R_h as measured in inches, as a gauge of the basic full-power DC generator value of rotor rotational speed, in a 'three-stage' device.

[7] The Specification Rotor Voltage (spec.V_r) should be numerically equal to 0.19332% of 1.5 million (1.5×10^6) times the vessel R_h as measured in feet, and is also equal to 0.9666 times the Nominal Rotor Voltage. This value would constitute the standard operating value of DC rotor voltage, as a function of the engineered Primary Power System output at a nominal design rotor rotational speed.

[8] The Peak (design operating maximum) Rotor Voltage (max.V_r) shall be equal to 110% of the Specification value thereof, and should likewise never be exceeded.

[9] The Specification DC Primary Array Voltage (spec.ΔV_p) will be equal to half (½) of the Specification Rotor Voltage, and affects all primary array electrode spacings.

[10] The design Primary Voltage Expansion Ratio for each Impulse Drive Unit should then be equal to the ratio of Specification Field Voltage to Specification DC Primary Array Voltage, and is once again a function of the ballast capacitor charge and of the primary cathode emissivity as in the case with Thermal Power Units.

Example of Specific Unit Voltage Values

Four-foot diameter model

Section A: Thermal Power Units

A 4 ft. EDF Generator constructed for use as a Thermal Power Unit would have specific Rotor and Field Voltages, according to the preceding instructions, as follows:

[1] The Nominal Rotor Voltage (nom.V_r) will be equal to 8,000.

[2] The Specification Rotor Voltage (spec.V_r) will be equal to 7,732.8.
